Hence, if the resistance opposed to the machine is susceptible of being varied, it should be rendered such that the velocity $V$ of the point of application of the equivalent force is one-third of the greatest velocity $V'$ which the power can produce if unresisted. Substituting this value of $V$ in the above equation for $F$ we get $F = \frac{4}{9} F'$; therefore $F$, the momentum of impulse, or the effect of the machine, becomes $\frac{4}{9} F' V'$ when that effect is a maximum, the resistance remaining unaltered.

If two bodies are connected together by a flexible line (supposed to be without weight) passing over a pulley at the common summit of a doubly inclined plane, the parts of the line being parallel to the surfaces of the two planes; the relation between the weights may be determined so that the momentum of that which is to be raised by the descent of the other may be a maximum. Let $p$ and $w$ be the weights of the bodies, or the forces of gravity acting on them vertically, and let $\theta$ and $\theta'$ be the respective inclinations of the planes on which they are placed, to the horizon; then $p \sin \theta$ and $w \sin \theta'$ are the forces of gravity on the planes, and consequently $\frac{p \sin \theta - w \sin \theta'}{p + w}$ is the accelerating force by which $p$ descends.

Now, by dynamics, the velocity of a body varies with the force and time; therefore, $v$ representing the velocity of $p$ or $w$, and $t$ the time of motion,

$$ v = \frac{p \sin \theta - w \sin \theta'}{p + w} \cdot t, $$

and consequently the momentum of $w$ varies with

$$ \frac{p \sin \theta - w \sin \theta'}{p + w} \cdot t. $$

This expression is to be a maximum; therefore, differentiating it, $w$ being the variable, and making the result equal to zero, the value of $w$ may be found in terms of $p$ by a quadratic equation: thus the required relation may be obtained.

If it were required to find, in any machine which when reduced to its most simple state may be considered as a lever or a wheel and axle, the ratio of the velocity of the moving power to that of the resistance to be overcome when the latter is a maximum, the following process may be used.

Let the arms of the supposed lever, or the semidiameters of the supposed wheel and axle, be represented by $r$ and $r'$, the power $p$ being applied at the extremity of $r$, and the resistance $w$ at that of $r'$. By the nature of the lever, $p = \frac{r}{r'}$ in the case of equilibrium; therefore, when the power is such as to produce motion, the motive force may be expressed by $p \cdot \frac{r}{r'} \cdot \frac{r}{r'}$, or if applied at the extremity of $r$. Now, in order to find the momentum of the inertia of $w$ at a distance $r'$ from the fulcrum may be made equivalent to the momentum of inertia of a body at a distance $r$, on representing such body by $p' r'$, we have $p' \frac{r}{r'} = w r'$: whence $p' = w \frac{r}{r'}$; the whole inertia to be overcome, if applied at a distance $r'$ from the fulcrum, will therefore be $p + w \frac{w r^2}{r}$, and the accelerating force at the extremity of $r$ will be

$$ \frac{p + w r^2}{r} = \frac{p' + w r^2}{r'} $$

But, by dynamics, the velocity of a body varies with the force and time; therefore, representing the velocity at the end of the arm $r$ by $v$,

$$ v = \frac{p' + w r^2}{r'} + \frac{w r^2}{r} + \frac{w r^2}{r'}, $$

in order to obtain the velocity at the end of the arm $r$, the expression for $v$ must be introduced in the ratio of $r'$ to $r$; therefore the velocity at the latter extremity varies with

$$ \frac{p' + w r^2}{r'} + \frac{w r^2}{r'} + \frac{w r^2}{r}. $$

This expression is to be a maximum; therefore, on differentiating it, $r$ being the variable, and making the result equal to zero, there will be obtained the ratio of $r' \cdot r$, which is the same as that of the velocities of $p$ and $w$ consistently with the condition that the velocity of $w$ is a maximum.
MAXIMUS, RUTILIUS, a Roman jurist, whose period is uncertain, but he probably wrote under Severus and Caracalla. The only work of his mentioned in the Florentine Index is Ad Legem Faelichian, or a commentary on the Lex Faelichiana. On (died 1326). There is one excerpt from Maximus in the Digest.

Q. CORNELIUS MAXIMUS, a contemporary of Cicero, was the master of C. Trebellius Tcesta, the friend of Cicero and Brutus. There are three fragments of his works: 1) letter to Brutus, 2) letter to Caesar, and 3) oration 48 (Dig. 38. 1. 16), which prefers his opinion to that of Servius on the use of adverbial sentences when conflated with the 'instrumentum,' the word 'instrumentum' comprised the rakes, spades, poles, and stakes.

MAY-FLY, the popular name of the Neuroptera insects of the genus Ephemeris and its allies. [Ephemeris, P.C.S.] Baetis (referred to Mayfly in P.C.S.) is one of the genera of Ephemerida. The Baetis venosa, an insect inhabiting a great part of Europe, is the type.

MAYER, SIMONE, a composer of great repute during the latter part of the last, and early in the present century, was born in Bavaria (at Sandersdorf, in 1760, according to Gerber; at Mendorf, in 1763, as stated by Lichtenhal). In 1778 he composed his 'Tres musicae'; in the same year 'La Ginerva di Socrate,' founded on the episode of Ariodante, in the 'Orlando Furioso,' which yet keeps possession of the Italian stage. In 1782 he died at his 'Kolhak,' [Avorno ed Asciola,' and 'La Rossa Bianca, e la Rossa Rossa,' a subject of the latter from the history of our wars of the Red and White Roses. But the greatness of his conceptions, and the most striking proof of the energy of his mind, are evidenced in his serious operas, 'Medea,' first made known in London by Madame Pasta, whose personification of the Sorceress of Colchis was by all acknowledged to be one of the finest historical exercises that any stage in any country had exhibited, and who did no less justice to the vigorous music of the composer than to the classical taste of the poet, the living and well known Signor Rosetti, who built his dramas on the foundation of the poet. The bold determination of Mayer (and also of Faer) to draw more effects from the orchestra—to give to his compositions a higher colouring, as well as deeper contrasts of light and shade—was, to say the least, a discovery—by no means at first with much opposition from the staidy non-progressive, and, through their influence, from the public generally. But the enlarged powers of the art thus obtained soon became apparent, overcame all resistance, and the Italy of our day adds another to the numberless instances of one extreme passing into its opposite; for the clamour of all kinds of braying instruments at present supplies the want of invention, may even of taste in plagiarism. Hence what Gretry un unjustly and expensively, if not justly, said half a century ago—that Mozart 'placed the statue of the poet, the pedestal on the stage'—may now with the strictest propriety be affirmed of the stage. In addition, that the statue exhibits nothing but distorted features and false proportions. Mayer died December 2nd, 1845.

MAYHEM. [MAXIMI, C. P. C.] MAYHEM. [MAXIMI, C. P. C.] NEVILLE, JAMES, born in 1604, in Devonshire. After having continued at Westminster school till nineteen years old, he was entered as a scholar of Christchurch, Oxford; and in 1631 he commenced M.A. Taking holy orders, he became chaplain to the king, and lived in the royal household. He was created D.D. in 1646. Firmly devoted to the royal cause, he was deprived of his student's place and chapelries, and banished from the city. After a life of suffering, he was restored to his living; he then became chaplain in ordinary to the king, a canon of Christchurch, and archdeacon of Chichester. He died at Oxford, in 1672, and was buried in the aisle adjoining to the choir of Christchurch. His works consist of a part of Lucian's Dialogues; and also several sermons and scattered poems. But he is now remembered only through the humour which marked his conversation, and which gave birth to two plays of his— 1. 'The City and the Country' 1658, folio; 1658, 4to.; 1659, 8vo.; and in the ninth volume of Dodalcy's 'Old Plays;' a work considerably more amusing than decorous, and especially lively in its satire on the Puritans; 2. 'The Amorous Warr, a tragi-comedy,' 1648, 4to.

MAZZOLINI, LODOVICO, a celebrated painter of Ferrara, sometimes called Lodovico Ferrarensis, was born about 1481. Mazzolino, like several other distinguished painters not Florentines, owing to the silence of Vasari regarding them, has only recently received his due meed of praise. His name is sometimes confounded with Mazzolino, a name given by Lumazza to Partenio, as the diminutive of Mazzola, and Vasari has noticed him slightly under the name of Malini, whom, says Lanzi, he has been divided into two—Malini and Mazzolino, and treated as two distinct scholars of Lorenzo Costa, instead of one and the same; an error which is not corrected by Baruffaldi, the historian of the Ferrarese painters, who appears to have had very imperfect knowledge of him. Mazzolino was nevertheless, in pictures of small dimensions and small figures, of the most masterly manner of the Italian painters. His works are miniatures of pieces, and are excellent in colour, light and shade, and expression; and even in composition they are equal to the best works of their style, the symmetrical. They are still more remarkable to the small works by Gardadio. Mazzolino generally painted architectural backgrounds, and these are remarkable for the beautiful detail of the ornaments and figures in basso-reliev, which are introduced into them. He died at Ferrara in 1550.

The works of Mazzolino are not numerous. There are several in the Capitol and in the Dom Church of Ferrara, four in the Gallery of the library, which is a valuable large picture on wood, of Christ disputing with the Doctors; it is marked MDXXIV. Zesar Lodovicos Mazzolinos Ferraren- nas. There are two also very characteristic works of this master in the National Gallery, in London; and two in the Gallery of Bologna. Besides these, there are very few authenticated works by this painter, many being no doubt ascribed to other masters, especially of the school of Mantegna. It is the case with a beautiful Nativity in the Florentine Gallery.

Lanzi, Storia Pictorica, &c. MECCA, the birth-place of Mohammed, and the holy city of the Moslems, stands in the situation of the land of Arabia which is called El Hedjaz or Hedj, about 21° 30' N. lat. and 40° 20' E. long., and seventy miles from the Red Sea, in a straight line. This city is situated in a narrow and sandy valley, the main direction of which is from north to south. The breadth of the valley varies from one hundred to seven hundred paces; the chief part of the city is placed where the valley is widest. In the narrower part are single rows of houses only or detached shops. The town itself, or that part where the houses are contiguous to one another and constitute one mass, covers a space of about fifteen hundred paces in length, but the whole extent of ground comprehended under the designation of Mecca amounts to three thousand five hundred paces in length. The mountains enclosing the valley are from two to five hundred feet in height, completely barren and destitute of shrubbery and wild vegetation. The rainfall is very small. Most of the town is situated in the valley itself, but there are some parts built on the sides of the mountains, especially on the eastern chain. The streets of Mecca are in general broader than those of eastern cities, the houses lofty and of stone, and the numerous windows that face the streets give them a more lively and European aspect than the streets of Egypt or Persia. Many of these houses are three stories high. In most towns of the Levant the narrowness of the streets contributes to their coolness, and in countries where wheel-carriages are unknown it allows two loaded pack-horses to pass the town with sufficient ease. In Mecca it was necessary to leave the passages wide for the visitors who crowd here. The only public place in the body of the town is the large
square of the great mosque, which is only enclosed during the Hadj (Pilgrimage) by the great number of well-stored shops. The streets are all unpaved, and in summer the sand and dust are as great a nuisance as the mud is in the rainy season, during which they are scarcely passable after a shower.

Mecca is badly provided with water; there are few cisterns for receiving rain, and the well-water is too brackish except during the time of the pilgrimage, the lowest class of hajji drink it. The famous well of Zemzem in the great mosque is indeed copious enough to supply the whole town, but the water is not well tasted. The water is brought upon an ass from the vicinity of Ar'afat, six or seven hours distant. This aqueduct is wholly built of stone, and all those parts of it which appear above ground are covered with a thick layer of stone and cement. There are two places in the interior of Mecca where the aqueduct runs above ground, and in these parts it let off into small channels or fountains, at which some slaves of the sheriffs are stationed to exact a toll from persons who fill their water-pots.

All the houses in Mecca except those of the principal and richest inhabitants are constructed for the accommodation of lodgers, and divided into numerous separate apartments, each consisting of a sitting-room and a small kitchen. Since the pilgrimage has begun to decline, numerous buildings in the outskirts have fallen into ruin, and in the town many houses are no longer inhabited. Except four or five houses belonging to the sheik, two mediresses, or colleges, and the mosque, Mecca has no public edifices, and in this respect it is perhaps more deficient than any other Eastern city of the same size. Burckhardt remarks that the want of splendid edifices is to be imputed to the veneration which the inhabitants entertain for their temple, and which prevents them from constructing any edifice that might possibly rival it.

The mosque, called Beitullah (God’s House), or El Ihsan, is only remarkable for the Kaaba, which it encloses; for there are several mosques in other places of the East nearly equal in size and superior in beauty. The Kaaba stands in an open space, surrounded by colonnades; on each side there are four rows of pillars and on the other sides only three. They are united by pointed arches, every four of which support a small dome, plastered and whitened on the outside. The number of these domes is one hundred and fifty-two, and that of the pillars is variously stated at four hundred and fifty and five hundred. The columns are from one foot and a half to one foot and three-quarters in diameter, and above twenty feet in height, but otherwise there is little regularity in them. No two capitals or bases are exactly alike. The capitals are of coarse Saracen workmanship, and some, which had served for other buildings, have, by the ignorance of the workmen, been replaced by better ones.

Seven paved causeways lead from the colonnades towards the Kaaba, or Holy House, in the centre. The whole area of the mosque is upon a lower level than any of the streets surrounding it, and is a descent of about half a mile, from the gates on the north side into the platform of the colonnade, and of three or four steps from the gates on the south side.

Towards the middle of this area stands the Kaaba, which, according to the belief of the Mohammedans, was constructed in heaven two thousand years before the creation of the world, and Adam, the first believer, erected the Kaaba upon earth on its present site, which is exactly below the spot which it occupied in heaven. It is an oblong massive structure, eighteen paces in length, fourteen in breadth, and from thirty-five to forty feet in height. It is constructed of the greatest size of little square blocks of different sizes, jointed together in a very rough manner and with bad cement. It stands upon a base two feet in height, which presents a sharp inclined plane. As the roof is flat, it has at a distance the appearance of a perfect cube. The only door leads into it opened only two or three times in the year: this door is on the north side, and about seven feet above the ground; it is entered by wooden steps. At the north-eastern corner of the building is the famous Black Stone; it forms a part of the sharp angle of the building, and is four or five feet above the ground. It is an irregular oval, about seven inches in diameter, with an undulating surface, composed of small, perfect cubes, each one of a different size and shape, well joined together with a small quantity of cement and perfectly smooth. Every pilgrim kisses this stone. As its surface has been much worn by the kisses and reaches of the place, it is difficult to determine the nature of the stone. It appeared to Burckhardt to be a lava, containing several small extraneous particles of a whitish or of a yellowish substance. The colour is now a deep reddish brown approaching to black. The four sides of the Kaaba are covered with a black silk stuff, hanging down to the roof bare. This covering is renewed annually at the time of the hadj, and is brought from Cairo, where it is made at the expense of the Turkish sultan. An opening is left for the black cloth which is supposed to be put on by the women after a period of fifteen days before the new one is put on. The black colour of the covering spread over a large cube in the midst of a vast space, gives to the Kaaba a singular and imposing appearance. As it is fastened slightly, the least breeze causes it to move with a slow undulation, which is hailed by the assembled congregation as a sign of the presence of the guardian angels, whose wings by their motion are supposed to produce the waving of the covering.

Seventy thousand angels have the Kaaba in their holy care, and are ordered to transport it to Paradise when the trumpet of the last judgment shall be sounded.

There are several other buildings within the area of the mosque, mostly appropriated to reading prayers, preaching, or the performances of devotions. The Zemzem, or holy well, is supposed to be the spring found in the wilderness of Hagar, at the moment when her infant son Ismael was dying of thirst. It seems probable that the town of Mecca owes its origin to this well; for many miles round no sweet water is found, and where this spring has been discovered men have supplied a copious supply. It is enclosed by a square building of massive construction, with an entrance to the north opening into the room which contains the well. This room is beautifully ornamented, and the objects of amusement are intended to be joined to it, but having a separate door, is a small room with a stone reservoir, which is always full of Zemzem water; this the hajji get to drink by passing their hands with a cap through an arched grating, which serves as a window, and into the reservoir without entering the room. From before dawn till midnight the well-room is constantly filled with visitors. It is considered a miracle that the water of this well never diminishes, and has never even overflowed the reservoir. The ascent to the Kaaba is made by a covered staircase, on which is a window looking into it. Burckhardt learned that the water flows at the bottom of the well, and that it is supplied by a subterraneous rivulet.

The revenue of the mosque is considerable, there being few towns or districts of the Turkish empire in which it does not possess property in land or houses; but the rest of this property is often withheld by the provincial governors, or at least is reduced by the hands through which it passes, to a small proportion of its true value.

The inhabitants of Mecca, with few exceptions, are Arara from different countries; but they have amalgamated, and they wear the same dress and have adopted the same customs. They have two houses, one in Mecca and the service of the Beitullah; but the former has the preference, and there are very few ulama, or persons employed in the mosque, who are not engaged in commercial affairs, and who are on steps from the Kaaba. With the exception of a few potteries and dyeing-houses, the people of Mecca have not a single manufacture. During the hajj Mecca becomes one of the largest fairs in the East, and certainly the most interesting, from the variety of nations which frequent it. The merchants of the place make large profits during this time by their merchandise.

They have also a considerable trade with the Bedouins, and especially with the inhabitants of the towns of the Nadj, who in want of India goods, drugs, articles of dress, and corn. The greatest profit however is derived from supplying food to the large numbers of pilgrims, and twenty times the consumption of grain is much greater in Arabia than in any of the surrounding countries, for the great mass of the population live almost entirely on wheat, barley, lentils, and rice, covered with black and white cloth, and have establishments at Jidda, whence they receive all their merchandise.

Mecca was, up to recent times, governed by a sheik, who was raised to that dignity by the famous Black Stone, and the consent of the powerful sheik families of Mecca. He held however his authority from the Turkish Sultan, who invariably confirmed the individual who had got possession of the government. The government of different states has been diminished, and the Porte was no longer able to send large armies with the hajj caravans, the sheiks of Mecca being entirely independent, and disregard the orders of the Porte. But Mohammed Ali of Egypt has restored the
authority of the Osmanis in the Hedja, and usurped all the
power of the sherif, allowing to the present sherif merely a
nominal sway. The sherif is chosen from one of the many
tribes of sherifs, or descendants of the Prophet, who settled in
the Hedja; the number of these tribes is now reduced to a
few families of Mecce.

The succession is not hereditary, but although it seldom takes place without some
contest, there is little bloodshed in general; and though in-
stances are rare where, for any reason, the choice of those
princes is withheld, the principles of honour and good faith which distinguish the
wars of the Desert have generally been observed.

(Burchardt's Travels in Arabia; All Bey's Travels in Morocco,
Tripsid, Cyprus, Egypt, Arabia, Syria, and Turkey.)

MECHANICAL POWERS is the name given to certain
simple machines or engines, for these words are applied in

indifferently, either of which is occasionally used by itself in
moving bodies or raising weights, or any of which are com-
bined together in the formation of the complex constructions
which are employed in manufactures and the arts. Frequently
however, in investigations relating to statical equilibrium, the
properties of the mechanical powers are introduced when no
machine is contemplated; as when, at some part of a plane
surface, the effect of a pressure at another part is determined by
the ratio of the distances of the point of application from a
certain point of support.

The several machines to which the name of mechanical powers is applied are the Lever,
the Wheel and Axle, the Inclined Plane, the Wedge, the Screw, and the Pulley.

The Levers are of three kinds; as the fixed fulcrum, the movable fulcrum, and the
free fulcrum. In the first, the fulcrum is placed under words in the body of this work, and the last in the
Supplement.

The object proposed in every machine is to transmit a force from
one part of a body to another, and is generally applied to that
power which is to be overcome or some operation to be
performed; and, in the transmission, the intensity of the
motive power is to be increased so that effects may be pro-
cured which could not be accomplished by the motive power alone.

The increase of the power is obtained by causing part of the
resistance which is to be overcome to rest on the machine or
on the fixed points which serve for its support, so that only the
reduced power is supposed to do the work. Thus, if it be required to raise a heavy body to a certain height from
the ground, no exertion of human or animal strength may be
sufficient, if directly applied, to accomplish the end; but if a
plane is inclined to the horizon and extending from the object to
the spot to which the latter is to be raised, the object can be placed on its foot, the force of gravity in the
vertical direction being resolved into two forces, one of which
is destroyed by the reaction of the plane, the other may be
overcome by a motive power less in intensity than that which
would be required if a direct application of force were
made; or several forces which will suffice for the attainment of the
end diminish in proportion as the length of the plane is
greater.

The manner of overcoming a resistance, which is specified in the
above, will serve also to explain the fact that in every application of a mechanical contrivance to
overcome a resistance, as much advantage is lost in respect of
time or space as is gained in respect of power. For it is evi-
dent that, in order to raise the object vertically through a space
equal to the height of the plane, it would be necessary to
move it over a space equal to the length of the plane; that is,
through a space which bears the same ratio to the vertical
height as the weight of the object bears to the power required to
move it up the plane.

An account of the applications of the mechanical powers in
the construction of complex machines would involve descrip-
tions of a vast variety of arts and sciences, and in the
abridged or dispensary, and the reader is referred to works which machines or engines are expressly
described, such as Gregory's 'Mechanics,' vol. ii., and Barlow's
'Treatise on Manufactures,' in the Encyclopædia Meto-
politana. (1)

In determining the efficacy of the mechanical powers it is
evidently necessary to consider their parts as mathematical lines,
and the ratio of the parts. The parts are, without a doubt, une-
qual weights, and, in order to reduce such a lever to a state from which the exact relation
between the opposing powers may be found, the weight of each arm
must be computed, and being, in imagination, applied at the
centre of gravity of the arm, the product of the weight multi-
plied by the distance of the centre of gravity from the
fulcrum is to be added to the momentum of the weight
which is actually applied at the point of action of the lever.

The sums of these moments, when the actual mechanical
conditions are given, enable us to determine the relation
between the opposing powers. The conditions of equilibrium being determined,
the excess of the power which enters into those conditions will evidently overcome the resistance, or
produce motion in the machine.

MECKLEN, MEKLEN, or MECHELEN, ISRAEL VAN, a celebrated
artist of the sixteenth century, born probably at Mecken near Bocholt, in the
bishopric of Münster, though this is a matter of speculation,
and his name is written in a great variety of ways, but
the above form has met with most supporters, as it is found writ-
ten in full on his tombstone and upon two of his prints:

some however have supposed that the engraver and painter
were two distinct artists, or that Israel van Mecken is not
Meister Israel the painter mentioned by several old writers.

There are eighteen beautiful old oil-paintings in the Pina-
kothek at Munich, and in some other collections, which
are attributed to Meister Israel; they are of the Van Eyck
school, but most of them have been found in the neighbour-
hood of Cologne and Cleveux, which is one of the reasons
for concluding that Mecken in Westphalia was the artist's
birthplace, notwithstanding Meckelen near Boon is in the
province of Gelder, where the artist is said to have
resided. Nevertheless, Lord Schlotheim is very evidently in favour of Mecken, as Israel
was buried at Bocholt, and he appears to have resided there.

In Ottley's 'Early History of Engraving' there is a print from a drawing in the
library of the late Mr. Vandyke. It is of the Israel's tombstone (since lost), which contains an inscription
in the old Gothic character to the following purport:-

In the year of our Lord 1605, died Master Israel van Meck-
len; his soul rest in peace, Lord. Israel van Mecklen, the
maker of oil-paintings, was born in the fifteenth
century, and is a representative of his nation. Thus, the
年限 of his birth is given as 1505.

Israel Van Mecken was evidently an engraver, from the
signatures on his numerous prints, and we know him to have
been a goldsmith, from accounts in the old Bocholt records in
which his name occurs, from 1492 to 1505 inclusive; but he
is on no occasion mentioned as a painter. Yet a painter of
the name of Israel is mentioned by several writers, and
among them by Jacob Wymefeld, in his 'Rerum Ger-
manicarum Epitome,' c. 67, 'de pictura et plastica,' but from
this very circumstance it is argued that the goldsmith and
engraver Israel van Mecken cannot have been the painter
Israel Allemannus mentioned by this writer, as he was not
known until the first part of the fifteenth century, and is
therefore not the artist who painted "Venus in the
Wymefeld's" picture, which, as it is not possible to say this
picture was executed by Abraham Beer, the list.

Wymefeld, however does not say picturae or tabulaver: in
pectore, but icelis Allemanni, which may mean prints as well
as pictures, and hence it may be inferred that he was
influenced by and contemporary with Albert Düür, while he
noticed Martin Schoen, or Schongauer, an excellent engraver, as
already dead, of whom he says, 'qui fuit tam eximius.' He
generally clearly writes a time when engravings were not
only known, but very generally spread over Europe: his book
appeared first in 1605, at Strassburg, only two years after the
death of Israel van Mecken. From these facts it is
evident that there are not, as far as Wymefeld Concerned,
the slightest grounds for disputing the identity of Israel van
Mecken the engraver and Israel Allemannus the painter.

Lomazzo, in his 'Trattato della Pittura,' which was
published in 1568, in a famous book on art and
entitled 'Miheum,' gives an account of a painter
Israel. He calls him Israel Metric (Meken), and says
he was the master of Martin Schöen; but if we substitute pupil
for master we shall probably have the truth, for Israel studied
engraving or painting, and there are numerous prints made by him of Martin's prints. It is remarkable that out of the
three hundred prints and upwards, attributed with and
without certainty to the Israel, one only has the date fixed to it, and
that is the Virgo, or a Virgin and Child, which was upon
the half-moon, with the infant Christ on her left arm,
and in her right-hand a crucifix; the whole surrounded by
a glory of angels. On the margin of this print is 'Diua maculat
Tabulae pictae a diebus' (no date given), followed by his
signature and date.—'Israe1 V. M. A.' 1602,' the being re-
versed. It is No. 44 in Heinicke's list. His prints are
generally signed Israel V. M.: I. V. M.: I. M.; and sometimes
Israe. alone. He has engraved his own portrait twice: in one, his name is signed in full 'Israël van Meckenem, gold-smith'; the other, in which his wife is also engraved, is marked 'Francesco Israelis et Ioanni Georgii'.—J. V. Ysbr. The pictures attributed to Israël van Meckenem, upon what authority is not explained, are all upon gold grounds and upon panel. They are some of them on a large scale, many of the figures being above life size. In execution of life they are equal to any works of their style extant; their expression is often excellent, and the colouring very clear, forcible, and effective. The Ascension and Coronation of the Virgin, Joachim and Anne at the golden gate, and several pictures of Apostles, in the Pinacothek at Munich, are very beautiful works, and if by Van Meckenem, he is evidently entitled to rank with the Van Eycks, Wilhelm von Köln, Hans Burgkma, Lucas van Leyden, and other distinguished masters of that time and school. Some of these pictures were drawn in lithography, in 1829, by N. Strixner. The supposed signature of Van Meckenem, with date, on a picture in the gallery of Vienna, mentioned in the catalogue of Von Mechel, is according to Bartch an error.

(Heleneke, Neue Nachrichten von Künstlern und Kunstsch.; Florillo, Geschichte der Zeichnenden Künste, &c.; Bartch, Peintres-Crest; Becker, Kunsthistor., 1839; Nagler, Neues Allgemeines Künstler-Lexicon; Dills, Gemälde in der Königl. Pinakothek zu München; Brulliot, Dictionnaire des Monnemarces, &c.)

Medicago (from medike, a beetle, and kuke, a resemblance), a genus of plants belonging to the natural order Papaveracae, and formerly referred to Papaver. This genus stands between Papaver and Argemone. It has 4 petals, numerous, short-styled, and many free stigmas, the capsule obovate, opening by pores beneath the apex.

There is but one species, M. Cambrica, the Welsh Poppy, and this is native of Great Britain, but it is a rare plant. It is also found in many parts of Europe. It is a biennial, which are very fuchas, and are seated on long peduncles which are infested before the opening of the flower, so that the flower-bud is drooping. It is an ornamental plant, and may be introduced into the garden. It will grow in a rich light soil, in a shady situation. It may be propagated by dividing the roots, or by seeds.

Medicago (from mughe, the Greek name of one of the species), a genus of plants belonging to the natural order Leguminosae, to the tribe Loteae, and the subtribe Trifolium. It has the calyx somewhat cylindrical 5-cleft, the keel rather removed from the vexillum; the stamina dinelephous; the legume many-seeded, of various forms, reniform, falcate, or costelate, but usually twisted in a spiral manner. The species are herbs or shrubs, with the stipules usually cut; the leaves trifoliolate, the leaflet usually toothed, and the pod long-tubed, flowered. They are numerous, upwards of eighty species have been described.

Medicago, Lucern, has many-flowered racemes; the pods compressed, spiral, with two or three turns, downy, unarmed, but shorter than the calyx; the leaflets obovate, oblong, dentate above, emarginate. This plant is a native of Europe, and is found wild in England and Scotland. It has an erect stem, with yellow or violet flowers. It is commonly cultivated in the fields of Europe (Lucanus, P. C.), and Babington says that 'the wild specimens found are scarcely naturalised.' This is the mughe of Theophrastus, 'Plant. de Caus.' ib. 2, cap. 20; and the Medicago of Flinia, ib. 18, cap. 10.

Medicago, Falcata, has the racemes many-flowered, the pods compressed, sickle-shaped, downy, unarmed; the pedicels shorter than the calyx, longer than the vexillum; the leaflets obovate-oblong, decurrent, emarginate. It is a native of Europe on dry mountainous pastures. In England it is a rare plant, but is occasionally found on dry gravelly banks and old walls. L. V. the species is said to be the Lucern which is cultivated in Switzerland.

Medicago, Lupinula, Black Medick, or Black Nonsuch, has many-flowered dense oval spikes; the pods compressed, kidney-shaped, with a spiral point rugose with longitudinal branched prickles. The leaflets are acute, the stipules sessile, and the leaflets roundish-obovate, dentilicate above, emarginate, mucronate. It has a procumbent stem with yellow flowers, and is a native of Europe in meadows, pastures, and waste ground, and is very common in Great Britain. It affords excellent fodder for sheep, and must be treated in the same way as lucern.

Medicago, Arbor, Tree Medick, is a villous shrubby plant; it has obovate-cordate leaflets nearly entire; the stipules linear, acute, entire; the peduncles racemose; the legumes stipitate, twisted, reticulated from transverse veins; 2-3-seeded, the seeds somewhat flat, the fruit achenes, the fruiting head a large coma of down. The species which is native of the south of Europe, and appears to be the eurinum of Theophrastus, 'Hist. Plant.' ib. 4, cap. 5; ib. 1, cap. 9; 'De Caus. Plant.,' ib. 6, cap. 6; and the sererov of Dioscorides, lib. 4, cap. 113. The cited species is Medicago rumphii, Fl. lib. 18, cap. 24; Virgil, 'Ecl.' i. 79; 'Georg.' ii. 431.

Besides the first three species, described above, M. maculata, M. minima, and M. dentiugata are natives of Great Britain. M. maculata, and M. dentiugata were introduced into the British Flora as growing on the sea-shore at Oxford in Suffolk; Mr. Babington, in his 'Manual,' states that he is convinced, from personal observation, that no such plant now exists in the British Flora. The species of this genus is propagated by cuttings. In cultivation the species may be easily raised from seed, and the shrubby species propagated by cuttings. The perennial herbaceous species may be propagated by dividing their roots.

(Babington, Manual Brit. Fl.; Fras, Synopsis Plantarum Flora Classicarum.)

Medici, Gian and Giaimo, Marquis of Marignano, born at Milan in 1450, was the son of a steward of the Duke of Milan. He entered early the military profession, in which he showed great courage, accompanied with a want of all principle. In the war between the Italian states and France, for the defence of the duchy of Lombardy, Medici took the part of his countrymen, and served under Pescara in the campaign of 1522, in which the French were driven out of Lombardy. He acquired the confidence of the Duke of Milan, to whom he was devoted, and who employed him to murder Astorre Visconti, a descendant of the former dynasty of the dukes of Milan, who gave umbrage to the actual occupant of the ducal throne. Medici, having committed the deed, was sent to assist in recovering the castle of Musso, situated in the mountains above the lake of Como, which was still held by the French. He succeeded in taking possession of it, and kept it for himself for years. After returning from his expedition, he went to Rome, and making predatory incursions among his neighbours. When Francis I. again invaded Lombardy, in 1526, Medici made an incursion into the Valley of the Ticino which belonged to the Grisons, and took possession of Chiavenna. The Grisons, alarmed for their own country, recalled their troops which were serving as auxiliaries in the French camp, and this defection is said to have contributed to the defeat of King Francis at Pavia. In consequence of this disaster, Medici was acknowledged by the duke as feudatory of Musso and other places, with the title of Chatelan.

In the subsequent quarrel between Duke Sforza and his overbearing wife, who wished to place himself at the head of the disaffected Milanese emigrants, and annoy the Spaniards, but after a time, the Spanish governor of Milan succeeded in conciliating Medici, on whom he conferred the title of Duke of Musso; the latter, on the other hand, carved out a principality for himself at the expense of his neighbours. He again invaded the Vallassina and took Bergogno. At last, in the year 1529, Duke Sforza, partly by force, and partly by offering him a sum of money with an annuity and the past, made him give up Musso and his other strongholds. Medici then retired to Piedmont and entered the service of the Duke of Savoy. Here his career as an adventurer terminated. Medici afterwards served in the campaign of 1556 against the French in Piedmont. Having returned to Milan after the death of Duke Sforza, he was made Marquis of Marignano by Charles V. He then went to Spain, from whence he accompanied Charles in his expedition against the revolted Flemings. From thence he went to Hungary to fight for the emperor against the Turks, and afterwards he served in Germany under Charles himself against the Duke of Saxony. Returning to Italy, Medici was appointed to the command of the expedition against Siena, which city he took after a long siege in the year 1555. On his return he was received by Duke Cosimo I. of Tuscany at Florence, with great honours and distinctions. The young Medici Tuscany, to the Medici of Tuscany was acknowledged by Cosimo, notwithstanding which it is still greatly doubted, or rather disbelieved. On his return to Milan, Medici fell ill and died in November, 1563, of a disease of long standing. He attended him in his last moments. His body was buried at Marignano with great pomp, but afterwards his brother Cardinal Giovanni Angelo Medici having become pope, in 1545,
MEDINA, the second holy city of the Mohammedans, and the place where their Prophet was buried, is situated in that part of Arabia which is called El Hedjaz, or Hedj, about 120 miles from Yembo, the town of Yembo on the Red Sea, which is the harbour of Medina.

Medina is built on the elevated plain of Arabia, not far from the eastern base of the ridge of mountains which divide the table-land from the lower country between it and the Red Sea. The town stands on the lowest part of the plain, in which the watercourses unite, which produce in the rainy season numerous pools of stagnant water, and render the climate unhealthy. Gardens and date-plantations, interspersed with fields, enclose the town on three sides; on the side towards Mecca the rocky nature of the soil renders cultivation impossible.

The city forms an oval about 3800 paces in circuit, ending in a point. The castle is built at the point on a small rocky elevation. The whole is enclosed by a thick wall of stone, between five and six feet thick, and about six feet high; towers and surrounded by a ditch: it is well fortified for an Arabian town, and has always been considered the principal defence in Hedjaz. There are well-built gates leading into the town. The houses are well-built, entirely detached and two or more stories high. As the stone is of a dark colour, the streets have rather a gloomy aspect, and for the most part very narrow, often only one or two paces across; a few of the principal streets are paved with stone. The dimensions in the number of pilgrims of late years has caused a great part of the houses to fall into decay. There are only two large streets which contain shops. There are very few large buildings within the precincts of the city. The great mosque containing the tomb of Mohammed is the only temple. There are two fine mosques or colleges. The castle, standing at the western extremity of the city, is surrounded by strong walls and several high and solid towers. It contains sufficient space for 600 or 800 men, has many arched roofs, bomb-proof, and may be deemed impregnable against an Arabian foe. It contains a deep well of good water.

The suburbs extend on the west and south of the city, and cover more ground than the city. They are separated from it by an open space, narrow on the south, but forming on the west a space of some miles; it is of so close a cover of shrubs and trees. This open place has no walls, but on the outside they are enclosed by a wall of inferior size and strength to that of the city. Four gates lead through this wall from the suburbs into the city, and consist of two rows; there are also large court-yards with low houses built round them, and separated from each other by gardens and plantations; they are inhabited by the lower classes of the town and all those who are without houses or who cannot afford houses. This enclosure is about forty families, so as to form a hamlet by itself. The castle are kept in the midst of the court-yard, where there is a large well, and the only entrance is shut at night. In the western portion of the suburb are regular and well-built streets with houses resembling those of the city. There are two mosques in the suburbs, one of which is called Medjed Ali, or the mosque of the prophet's cousin.

The town is supplied with sweet water by a subterraneous canal which runs from the village of Koba, about three-quarters of a mile distant in a southern direction. The water is abundant, and in several parts of the town steps are made to carry it to the principal houses, and in about thirty places it is sold. There are also many wells scattered over the town; every garden has one, by which it is irrigated; and when the ground is highly cultivated the water is applied in abundance. Water is found in abundance on the various heights and on the slopes of the highlands, from the higher grounds to the lower depression in which Medina is built, and part of the city is inundated. All these circumstances, and the scarcity of water in the environs of Medina, a circumstance which made the city especially convenient for the considerable settlement of Arabs long before it became a

The mosque containing the tomb of Mohammed bears, like that of Mecca, the name of Haram, on account of its inviolability: but in other Mohammedan countries goes by the name of Medjed el Naby (Haram of the Prophet). The mosque of the Prophet was the place of the first compilation of the Koran. It is situated towards the eastern extremity of the city, and its dimensions are much smaller than those of the mosque at Mecca, being a hundred and sixty paces in length and a hundred and forty-three in breadth: but it is not built upon the same plan, forming an open square surrounded on all sides by covered colonnades, with a small building in the centre of the square. The colonnades are much less regular than those of Mecca, and the southern parts of the colonnade is composed of ten rows of pillars behind each other; on the western side are only four, and on the northern and eastern sides only three rows. The columns themselves are of different sizes. On the southern side, where the prophet's tomb stands, and which forms the most holy part of the building, they are of larger dimensions than in the other parts, and about two feet and a half in diameter. They have no bases and the shafts rest on the ground. The columns are of stone, but being all plastered white it is difficult to decide in what kind. The roof of the colonnade consists of a number of small domes, white-washed on the outside. The interior walls are covered with arabesques, and each one of the four principal sides is divided into one and part of the southern-eastern corner, which are cased with slabs of marble, nearly up to the top. The floor under the colonnades on the western and eastern sides is paved and is nearly covered with sand, as is likewise the open square. On the southern side the floor is paved with fine marble across the whole colonnade, and in these parts the floor of the tomb of Mohammed is paved with a plan, of mosaic, of excellent workmanship. Large lofty windows, with glass panes, admit the light through the southern wall; some of them are very well painted. On the other side there are smaller windows along the walls, but they are neglected.

Near the southern-eastern corner of the mosque stands the famous tomb, detached from the walls so as to leave between it and the southern wall a space of about twenty-five feet, and fifteen between it and the eastern wall. The enclosure which protects the tomb from visitors, forms an irregular square of about twenty pieces, in the midst of the colonnade, several of its pillars being included within it; it is an iron railing painted green, about two-thirds of the height of the columns. The railing is of good workmanship in imitation of filigree, and is decorated with open-worked inscriptions in yellow bronze. This is the actual grave of the Prophet. Within the interior except by several small windows, about six inches square, which are placed in the four sides of the railing, about five feet above the ground. On the southern side, which contains within the railings the two rows of colonnades, there is a recess so contrived that when praying, the railing is thinly plated over with silver, and the inscription 'There is no God but God, the evident truth,' is repeated in silver letters across the railing. The colonnades consist of three open gates, three of which are constantly kept shut, and one only is opened every morning and evening to admit the eunuchs, whose office it is to clean the floor and light the lamps. The enclosure is called el Hedjra. Permission to enter it is granted gratis to people of rank, and may be purchased by other people, from the principal eunuchs, for about twelve or fifteen dollars; but on entering the enclosure nothing more is to be seen than what may be observed when peering at the windows of the railing. At the distance of only a few paces from the railing is a curtain carried all round; it is equal in height to the railing. It is made of a rich silk brocade of various colours interwoven with silver and gold, and adorned with a band of inscriptions in golden characters running across the middle of it. This curtain has a small opening at the northern end, which is always shut, no person being permitted to enter except high eunuchs, the chief eunuchs, who take care of it, and who put on during the night the new curtain sent from Constantinople, whenever the old one is torn or worn out. The window it leaves open is in the northern or western side of the enclosure. The old curtains are sent to Constantinople, and sent to cover the tombs of the sultans and princes.

According to the historians of Medina the curtain covers a square building of black stone and supports a roof the interior of which are the tombs of Mohammed and his two earliest friends and successors, Abu Beker and Omar. These
toms be deep holes, in which the coffins are deposited; that of Mohammed is cased in silver. The floor between the curt-
ain and the galleries is inlaid with variously coloured marble in mosaic; glass lamps are suspended all round the curtain, and every evening the ornaments burn in all night. The whole of the enclosure is covered with a fine
lofty dome rising far above the domes which form the roof of
the colonnades, and is visible at a great distance from the town.
As soon as ingress to Medina catch sight of it they repeat some prayers.

Near the curtain, and within the galleries, is the tomb of
Seuta Fatime, the daughter of Mohammed and wife of Ali; it is a close, with walls covered with a richly embroidered black brocade, and without any other ornament.

Mohammedan tradition says, that when the last trumpet shall sound Ayas (Jesus Christ) is to descend from heaven to
the earth, and to announce to the inhabitants the great day of
judgment; after which he is to die, and will be buried in the
Hegira by the side of Mohammed; that when the dead shall
rise from their graves, they will all rise together and ascend
to heaven, where Ayas will be ordered by the Almighty to separate the faithful from the infidels. In conformity with this
tradition the spot is pointed out through the curtain of the
Hegira where the tomb of Ayas will be placed, and guarded.

Four gates lead to the interior of the mosque: a few steps are
to be ascended from the neighbouring streets up to the gates, the area of the mosque being at a somewhat higher level. The gates are usually closed about two hours after sunset the gates are generally shut by means of folding doors coated with iron, and not opened till about an hour before dawn; but those who wish to pray all night in the mosque obtain permission from the commanding guard, who sleeps near the Hegira. During Ramadhan the
mosque is kept open the whole night.

The inhabitants of Medina, like those of Mecca, are not
Buddhists but strangers, who have come to the place as pil-
gri
gs and afterwards settled there, or they are descendants of
such strangers. Medina is not so great a place of commerce
as Mecca, and the merchants are not so rich, but it has the advan-
tage of a considerable trade attached to it for cultivation, and there are many wealthy landowners in the
town, who let out their possessions to poorer people. Wheat
and barley are cultivated, but the chief profit arises from the
plantations of date-trees, the fruit of which is held in greater
estimation than the dates of Egypt.

(Burchardt, 'Travels in Arabia'.)

MEDITATIO FUGAE WARRANT, in the law of
Scotland, is a writ by which a debtor, supposed to be about
to make his escape from the country, is arrested and kept in
custody, until he pay the debt, or find security to pay it if he
shall not, and liable to be proceeded against from its being an old consuetudinary practice in Scotland, which
happens to be in unison with the late legislation of
England on the subject of debtor and creditor. In Scotland
no action of arrest on a warrant can be brought, according
to the law of England anterior to the 1 & 2 Vict. c. 110, appears
to have been ever acknowledged; and it was only on the
ground that he was about to flee the realm, that a debtor
could be arrested, unless on the authority of a final judgment
of a court of law, or on the extracted registration of one of those
documents in which by a clause of registration for execution or
by commercial custom (as in the case of bills of exchange)
the grantor agrees to be put in the position of having a decree
recorded against him. A mediatic fugae warrant may be
granted by any judge having jurisdiction in questions of
debtor and creditor, as by a sheriff, a magistratus of a burgh, a judge of
an anterior court, etc. Where granted by a sheriff, the
late act, the advantage that it may be executed in any part of
Scotland, whether or not within the jurisdiction of
the sheriff who grants it (1 & 2 Vict. c. 110, § 25). The grant
of a mediatic fugae grant that at the
place, the oath of the creditor, who must distinctly set forth the
amount, nature, and origin of the debt. The debtor is
then brought before the judge, who, hearing the statement of
both sides, may, on his discretion, be satisfied that if the
magistratus on a distinct oath of debt should refuse to commit,
he is personally liable to the creditor for the consequences,
and that if, on the other hand, he grant a warrant on an
impossible statement, he shall be liable in damages to
the person committed. At all events a person desiring a
mediatic fugae warrant is liable to damages if he obtain it on
a false statement. A person imprisoned on such a warrant must
be liberated in six months, unless his further imprisonment be authorized by other judicial proceedings. By 6 & 6 Wm.
IV. c. 70, imprisonment for any debt under 8l. 6s. 6d. (100.
Scots) was abolished in Scotland, and it was lately found by
the court of session that mediatic fugae warrants come within the
act.

MEGALICTHEYS, a genus of fossil Ganoid fishes, from
the carboniferous strata of Edinburgh, Glasgow, Leith, Man-
chester, etc. (Agassiz, 'Recherches sur les Fossiles
Poissons'.)

MEGALODON, a genus of fossil Conchils, proposed by
Goldfuss. From the Devonian strata.

MEGAMORPHIA, a genus of ferns, found on the conti-
measures. (Arts. Antediluvian Phytology.)

MELALEUCA (from μῆλος, black, and λευξ, white), a
genus of plants belonging to the natural order Myrtaceae.
It has the calyx-tube nearly hemispherical, the limb 8-petate;
the petals 5; the stamens numerous, combined into 5 elon-
gated bundles, which alternate with the petals; the anthers
incumbent; the stilo filiform, the stigma obtuse; the capsule
comanate with and enclosed in the thickened tube of the caly-
x, which is sessile on, and adnate at its base, to the flower-bearing
branch, 3-seeded, many-seeded; the seeds angular. The
species are trees or shrubs with alternate or opposite entire
leaves, with white, yellowish, or purplish oil. They are
found
in the Antediluvian, and other East India islands.

MELARUMAGE, CASSIEPI, P.C.)

M. Leucodendron, White-tree, or Cajeput-tree, has alter-
nate long lanceolate acuminate filate 3-5-nerved leaves;
the flowers borne in clusters pendulous, the flowers in spikes
rather distant, which, as well as the racis, are quite gla-
rious. It is a native of the East India islands, and was at one
time supposed to yield the oil of commerce. Roxburgh asserts
that it produces an oil which it probable that this oil is
rarely or never used for the distillation of the oil which
is used in the European markets.

Upwards of thirty species of Melaleuca have been
described, the majority of which are natives of New Holland. Many
of them are fine plants with beautiful blossoms, and very de-
sirable for the conservatory or greenhouse. They grow well
in a mixture of peat, loam, and sand, and may be propagated
by cuttings, which will readily take root if planted in a pot
of sand and placed under a hand or bell glass.

(Mandley, 'Flora Medica; Don, Gardener's Dictionary.')

MELAMON, a genus of plants (lychnis, scutellaria),
which, a genus of plants belonging to the natural order Scrophulariaceae or Scrophulariaceae. It has a tubular 4-toothed calyx; a
ringent corolla; the upper lip compressed laterally with reflexed
margin by means of a depressed nectariferous tube; the sepals
expanded, ob-
lige academically compressed; one or two seeds in each
smooth. The species are annual plants, with opposite lanceolate
linear entire leaves, with opposite usually second terminal
flowers. Eight species are enumerated by Don, six of which
are European and two Americans. Of the six European four
are natives of Great Britain.

M. cristatum, Crested Cow-wheat, has the spikes densely
imbibed, 4-sided, and the bracts heart-shaped. It is a na-
tive of woods and thickets in the eastern counties of England,
and also generally of the north and middle of Europe.

M. aureus, Purple Cow-wheat, has lax conical spikes, and
orange-yellow flowers.

M. pratense has the flowers axillary, second in distant
pairs; the calyx closed; the upper lip protruded. It has
large pale yellow flowers. It is a native of Great Britain,
but not a common plant. It is said that it is a species of
M. pratense, with an open calyx, and lips equal in length.
It is a rare plant, and found in alpine woods.

(Mabon, 'Manual of British Botany; Don, Gardener's
Dictionary.')

MELASTOMA (from μῆλος, black, and στόμα, a mouth,
because the berries when eaten stain the mouth black),
a genus of plants, the type of the natural order Melastomaceae.
It was the tube of the calyx ovate, half-adhering to the ovary, densely covered with scales or bristles; the limb 5- rarely 6-cleft, the segments alternating with the appendages, both deciduous; the petals 6-5; the stamens twice the number of the petals; the anthers linear, a little arched, opening by a pore at the apex, each furnished with a stipe-formed connective, which is in some species elongated, and in others short, but always biseriate or emarginate in front; the fruitlet part of the ovary central and bristly; the style filiform, somewhat thickened at the apex; the stigma a pruinose dot; the capsule baccate, 5-6-celled, opening irregularly; the seeds carunculate. The second species of this genus are shrubs, which are usually covered with strigae. The leaves are peltate, and either quite entire or serrulate. The flowers are large, white, rose-coloured, or purple.

Melilotus, Malabar Melastoma, is a shrubby plant with tetragonal branches rough from strigae; the leaves elliptic-oblong, obtuse at the base, acute at the apex, quite entire, green on both surfaces, and scarious from strigae; the corollas 1-5-flowered; the calyx clothed with admixed strigose scales, with ovate acute lobes, the connectives of the anthers short, or very long. It is a native of the East Indies, and frequent in the Indian Archipelago. The leaves of this plant are employed by the natives, where it grows, as a remedy in diarrhoea, dysentery, and mucous discharges.

Between thirty and forty species of Melastoma have been described. They grow in the warmer districts of the Old and New World, in Asia, Africa, America, and South America. Their flowers are very handsome, and all the species may be cultivated for ornament. They grow well in a mixture of loam, peat, and sand, and young cuttings root freely in sand in greenhouses.

(Lindley, Vegetable Kingdom; Don, Gardener's Dictionary.)

MELICA, a genus of plants belonging to the family of Gramineae. It has rarely glaucous leaves, with lateral ribs, nearly as long as the ovate spikelet of 1 or 2 flowers rounded on the back, and a club-like rudiment of one or two more; the palisade hardening on the loose fruit; the styles terminal. There are two British species of this genus, M. xerophita and M. mutana, which are found in damp shady woods.

(Babington, Manual of British Botany.)

MELILOTUS (from μελίς, 'honey', and λοτος, 'lotus'), a genus of plants belonging to the natural order Leguminosae. It has a calyx with five nearly equal teeth, the keel obtuse, the filaments filiform, the ovary straight, the pod subglobose or oblong, 1-celled, 1-4-seeded, longer than the calyx, the petals distinct, deciduous. The species are herbaceous plants with stipules adnate to the petiole, and trifoliate leaves with usually toothed leaflets. None of them are ornamental plants as such; they are employed in florists' gardens, and in botanical collections. Two of the species are used as fodder for animals.

(Mellor, P. C.) Two species are found native in Great Britain. M. officinalis, the common Mellilot, has lax racemes, with the calyx short and the keel equal; the pod ovate, acute, compressed, transversely wrinkled, hairy; the leaflets serrate, truncate, narrowly ovate; the stipules setaceous, entire. M. vulgaris has the leaflets longer and keel equal, but shorter than the standard; the pod ovate, obtuse, mucronate, reticulate, rugose, and glabrous. It is a rare plant, and is found in sandy and gravelly places near the sea.

M. Messemaea, Messina Melilot, has an erect stem, with obovate-cuneate dentilicate leaflets; the stipules broad at the base, toothed, linear at the apex; the racemes few-flowered; the teeth of the calyx nearly equal, hardly shorter than the standard, very much narrowed, 1-seeded; the seeds ovate, compressed, large, black, rugose from dents. This plant is a native of Barbary, Sicily, Piedmont, and the Straits of Messina. It is the Lotus of Theophrastus, Pliny, and Dioscorides, and λάυρες ἅμαρτων of Dioscorides, lib. iv., cap. 171. It is also the Lotus of the Romans (Pliny, xiii. 17; xxxii. 21; Virgil, Georg. i. 84, and iii. 394).

The petals, the calyx teeth, and stamens are very much cultivated as ornamental plants. They may be easily propagated by seeds, which should be sown in the open border in spring. A light, very poor soil suits them best.

(Mcllwain, Manual of British Botany; Don, Gardener's Dictionary.)

MELISSA (from μέλισσα, a bee), a genus of plants belonging to the natural order Labiate or Lamiaceae. This genus has been defined according to the different views of systematic botanists. Bentham, in his monograph on the Labiate, has referred about 30 species to this genus. They are all known by the common name of Balm, and some of these species have been described under Calamintha, P. C. S.
The typical species of this genus are:

r_Melissa officinalis, borem by two Angeli, after a design by himself; and Pope Urban VIII., after Bernini. He enjoyed a great reputation during his lifetime; Charles II. invited him to England, and Louis XIV. granted him an annual pension, and gave him apartments in the Louvre. He died in England, in 1688. His engravings were much esteemed in France, and are still much admired. (Florent Le Comte, Cabinet de Singularités, &c.; Huber, Manuel des Amateurs, &c.)

MELIORE. The Linnean genus Meliora included the several genera of heterothallic Dipsacaceae, especially the family Cardiaceae, interesting on account of its including those beetles known under the name of 'bitterling flies,' and employed in medicine. The term mellio is now restricted to the aperous Callitrichus and the Sanguinaria, and all the species with large and swollen bodies, and short oval elytra, laying over each other at the base of the nuture. They are sluggish creatures and feed on various plants, especially the species of Myriophyllum. Some of them are often found in the leaves of the plants on which they are feeding. Their legs are oily, yellow, or reddish liquid. Latreille maintained that the insect was the bespritz of the ants, to which noxious qualities were attributed. (See his paper on the subject in the 11th volume of the Mém.
It is well clothed with wood, and presents one of its forest foliage. The upper part of the elevated ground is covered with small shining masses of ironstone having a metallic lustre as if they had been ejected from a furnace. The sloping sides are less stony, and the flat ground is generally quite free from stone. Streams of water are scarce, but the swamp water is generally drinkable, and by sinking wells a constant supply of excellent water is obtained. The swamps are generally full of long grass and reeds, intermixed with small trees. Narrow gullies cut up with a kind of cane or rattan (Flagellaria indices, Linn.) lead into these swamps.

The soil of the island is of inferior quality, paking of the character of the ironstone which is generally spread over it. The surface after digging two feet and a half is much better, being a brown mould of a saporous texture. Close to the shore the country is very rocky, and the soil is light and shallow, intermixed with sand and gravel. Bordering on the swamps it is richer and more productive, and it is supposed that some of the flats so situated are capable of producing rice.

Vegetation is very luxurious, and during the whole year there is plenty of grass for cattle. The timber is of general good quality, and although trees which are small in the stem predominate, there are many of considerable dimensions, and applicable to house-building, furniture, ship and boat building. The most common tree is the ironstone, of which the average height of trees to an acre is about one hundred and twenty, but in some places they amount to one hundred and eighty. Among these four trees several species of eucalyptus are most abundant. The eucalyptus is a wild tree.

The most common quadrupeds are kangaroos, opossums, bandicoots, native dogs, a small brown rat, and a species of squirrel. The Termeia bat or flying fox is very numerous. The birds are mostly distinguished by their beautiful plumage, especially some species of cockatoos and parrots. There are also several varieties of king-fisher (Dacelo gigas), swamp spoon-bills, quails, currawongs, wild ducks, sand-hawks, wild pigeons, several kinds of cranes, and a wild fowl of the gallinaceous order of considerable size. Many beautiful small birds are very abundant. The variety of states, nature, and length of life, is very great; some of them are venomous. There is also a great variety of lizards of beautiful colours: the largest are the frilled iguana (Chlamydosaurus Kingi), and the common iguana (Iguana delicatissima). All the birds above in Aspley Strait, and turtles are found at some places on the coast.

The most destructive of the numerous insects are the white ants.

The number of natives is rather large, considering that they lead a wandering life, and during the dry season live on kangaroos, opossums, bandicoots, iguanas, and lizards; and during the wet season on fish, turtles, crabs, and other shellfish. The marine产物 are the cabbage-palm and fruit of the sago-palm. They are evidently of the same stock as the natives of Australia, but they are more active, energetic, and enterprising. Their language is said to be so far different that a native of the southern coast could not understand one word of what they said. In the construction of their canoes, spears, and waddies, they show much ingenuity, although the workmanship is rough from want of tools. Their canoes, water-buckets, and the sheath of bark, are studded with strips of split cane. They are extremely diffident of strangers, and it was found impossible to enter into any friendly intercourse with them during the four years that the British flag has been hoisted on Aspley Strait.

The settlement on Aspley Strait, called Fort Dundas, was formed in 1824, for the purpose of attracting to it the commerce of the eastern part of the Indian Archipelago. But in 1828 the island was sold by the inhabitants of the island, and it was ascertained that the soil was far from being fertile, and the climate very debilitating to Europeans, although not absolutely unhealthy. These combined circumstances led to the abandonment of the settlement in 1828, but in 1837 a new one was established in Port Essington on Coburg Peninsula, a place which is visited by the inhabitants of Macassar and other islands, to fish for trepang.
Bruges, and he added very probably to Memling. Vasari apparently alludes to Memling when he speaks of Aunee (Anese) of Bruges. The dates of Memling's pictures range, according to the printed accounts, between 1450 and 1499. The most valuable of these are those of the Madonna of Aragon, wife of Philip of Burgundy; this picture is mentioned in the anonymous Journal published by Morelli in 1800 — Notizie d'Opeue di Degoeno nella prima Metà del Secolo XV. in its early form, painted by Memling, Bruges. Croma, and Venezia, scritta da uno Aunee di quel Tempo, in which the picture is called Mamertino or Memelino. If this date be correct, Memling must have been born before 1439. He was living at Bruges in 1467, and he may have been there nearly all his life. The date 1497 is found on a small picture in the possession of M. van Ertborn at Utrecht; it is also the year in which he finished some paintings for the Carthusian convent of Miraflores near Burgos in Spain, in which he is said to have died. It was not long afterwards: the account is given by Ponz, in his Viaggio de' Spagnoli.' This convent was destroyed by the French in 1412. Memling appears to have lived some years in Spain: he is supposed to be the Juan Flamenco of Flanders who was at Miraflores between 1496 and 1499, and perhaps later. He probably also visited Italy and Germany, and certainly Cologne; and he is said to have served Charles the Bold, Duke of Burgundy, both as painter and as warrior. The story is, that he was at the battles of Granson and Morat, in 1476; and in the beginning of 1477 was admitted, ill from wounds and distemper, into the Hospital of St. John at Bruges. It was a poor Hospital for old and injured soldiers. In five of these pictures the work is attributed to Memling, and the others are in his style. It was during his residence in this hospital that he painted the beautiful pictures which still adorn that hospital, and for which his name is, among the painters of the fifteenth century, one of the first of the painters of the fifteenth century.

The principal work by Memling in this hospital is the history, in minute figures, of St. Ursula and her companions, expatiately painted in oil, in many compartments, upon a red case of a gothic design, known as La Chasse de St. Ursule. This chasse, or shrine, has been the subject of a special work by Baron von Keverberg, intituled Ursula, Princesse Britannique, et ses peintres: Memling, Ghent, 1816. The paintings have been drawn in lithography by MM. Manche and Ghemard. Memling painted also during his stay in this hospital the small picture of the Adoration of the Magi, and the splendid large altarpiece of the Marriage of St. Catherine, both of which are still there.

The Marriage of St. Catherine, in which the figures are much larger than is usually the case in Memling's works, was painted in 1479, and is one of the most brilliant pictures of the fifteenth century. It is in three compartments, a centre and two revolving wings. In the centre is the marriage of St. Catherine, attended by saints. In the background are painted episodes illustrating the lives and martyrdoms of the attendants saints and of St. Catherine herself. The left wing is the beheading of John the Baptist; the right wing is St. Catherine of Alexandria. In the left compartment of Patmos: the last is a remarkably comprehensive composition. On the exterior of the left wing are two Hospital Brothers, the Apostle James, and St. Antony of Padua; on the right, exterior are two of the Hospital Sisters, with saints Agnes and Clara. There is an inscription on this work, but as it has been renewed, it cannot be taken as an authority in a difference respecting the signification of letters: it is however variously reported. There are three other pictures by Memling in this hospital: a Descent from the Cross, on wood, with two wings; the Madonna and Child, with a portrait of Martin van Nieuwenhoven, burgomaster of Bruges in 1497, on the wings of the picture; and a Madonna of the Virgin, and a female, inscribed 'Sibylia Sambetha quae est Petrae an: ante Christ nat. 2040.' There are other works by this painter in the Academy of Arts, and in other buildings of Bruges.

There is, or was in 1832, a small portrait of a young man in the costume of the hospital brothers of St. John, in the collection of Mr. Aders in London, which is said to be that of Memling himself. This is inscribed: 'Memlin' was painter to the Hospital St. John at Bruges, and a female, marked: Dr. Water well not mention it. Another very interesting work, by Memling, is the collection of Mr. Aders, the travelling altarpiece or altar of the Emperor Charles V., which was preserved in the cathedral of Bur-
anlying name. Few of Memmi's works now remain, and there are performed more performant that the principal among the frescoes of the chapter of the chapel degli Spagnuoli at Florence, painted in 1332: they consist of stories from the lives of Christ, San Domenico, Saint Peter Martyr, and part of the legend of the Dead Christ, restored to Pisa and transcribed in it.

In one of the last works are the reputed heads of Petrarch and Laura, but this story, as Lanzi says, is a mere fable, for Memmi did not paint Laura until four years after the completion of the frescoes, in 1336, and he was invited to Avignon.

[GADDI, TADEO, P. C. S.] There are also some stories by Memmi, from the life of San Ranieri, in the Campo Santo at Pisa: they are engraved in Lasinio's 'Fitture dei maestri della Schiuma.'

Simone painted also in miniature. There is a MS. of Virgil, with the commentary of Servius, now in the Ambrosian Library at Milan, but formerly in the possession of Petrarch, which is preceded by a miniature of Virgil seated with his pen in his hand, invoking the poetical muse; before him is Æneas in armour, with his sword, representing the Æneid; there are likewise a shepherd and a tiller of the soil, representing the Erotes and Georgics; and Servius is also there, drawing a fine veil to himself, as symbolical of the elucidation of his commentary. This design, supposed to have been made at the instance of Petrarch, is inscribed with the following couplet:

'Venus Virgilium qui talia semina fist, Seu talia Memmi dixit qui talia placet.'

Memmi died in 1344, according to the necrology of the Dominicans at Siena, aged sixty, according to Vasari, but much older according to Della Valle and some others.

Vasari, pointing out the inconstancy of style of Memmi, which he said was worthy of one of the moderns, his remaining works are not at all beyond his age, and he was surmised by the two Gaddi: his design is meagre and ugly. Of his portrait of Laura nothing whatever is known. The reputed head of Laura above mentioned is engraved in D'Agincourt's 'Histoire de l'Art par les Monuments,' Plate, ex. 22, and in Cigoli's 'Storia della Scultura,' Plate, ex. 43. The latter of these figures represents, however, some other reputed portraits of Petrarch and Laura, at considerable length in the third volume of his History. The only authentic portrait of Laura extant, of that age, appears to be a miniature in a MS. in the Bibliotheca Laurenziana at Florence, which however may have been copied from the original work by Memmi: there is an outline of this also in Cigoli's work, i. p. 42.

Vasari gives the following as the inscription on Simone's tomb, but he does not say where:—Simoni Memmi pictoris oris tonum omnis actae celeberrimae. Vixit ann. LXX. mens. il. d. ilij. —His chief excellence was invention.

Vasari, who was brother-in-law to Simone, assisted Simone in some of his works, and completed others which were left unfinished at his death. He was not equal to Simone, though a better colourist than he: there are a few of his heads in the antique manner which he was living.

[Vasari, Vite de Pittori, &c., and the notes to Schorn's German translation of Vasari; Della Valle, Lettere Senesi; Lanzi, Storia Pittorisce, &c.; Rumohr, Italianische Forschungen.]

MEMMI DI MARTINO. [Simone, P. C. S.] MENANDER, ARRIUS, a Roman Jurist, at the time of Severus and Caracalla. The only work of his mentioned in the Florentine Index is four books on Militaria. There are also excerpts from Menander in the Digest.

MERCHANT SEAMEN. [Sirev, P. C.] MERCER, LOUIS SERBAUEN, a prosperous writer on men and manners, politics, science, the drama, literary criticism, and many other subjects. The greater part of his works are sunk in oblivion, but several of them still deserve and obtain attention. He was born at Paris on the 6th of June, 1740. He was for some years professor of rhetoric in the college of Bordeaux. The works for which he chiefly deserveth attention at the present day are his attacks on the manners and institutions of his age. The first of these appeared in 1771, with the title 'L'An 2440;' Rêve, s'il en fut jamais.' In 1781 he commenced the publication of 'The Tableau de Paris.' Having courted the attention of the authorities to his anti-bullying works, which, had they been published in the hands of the liberal institutions of France, was sure to provoke their wrath, he found it prudent to retire to Switzerland, where he completed this remarkable work. Without holding with its author that the 'Tableau de Paris' produced the French Revolution, there is no doubt that it did much to open the eyes of mankind to the immoral and corrupt state of the social system of the French capital, and the inapplicability of the great national institutions of the country to supply their proper ends. It was frequently reprinted, and was translated into an animated, descriptive, and biting pen. He occasionally appealed to a high sense of morality, but his chief power lay in showing his readers the bad taste and the folly of the prevalent corruption, and in severely denouncing the base industry struggling against false social laws, or the remnants of prismatic simplicity holding out against the inroads of corrupting manners, his tone has dignity and feeling. When he speaks of the French, he is always careful to administer a wholesome diet of the artificial and vicious tides of the fashion, of the tenuity over the free expression of opinion, he overrules with sarcastic ridicule. The work is a curious anatomy of French society, and exposes many evil incidents to large cities, of which the lapse of sixty years has not entirely enabled us to find the remedy. The sanatory regulations which have lately so much occupied the attention of society, and other means of social organization, are intended to supply deficiences which Mercier points out in his own peculiar fashion: whether he could have devised remedies for the defects he discovers may be questioned. He was a master of paradoxes. In 1801 he published 'Néologie, ou Vocabulaire de Mots nouveaux, à renouveler, ou pris dans des Asceptions nouvelles,' a work in which he announced such propositions as:—'The name of France is a diminutive of France; it is the chief ornaments of French literature; seeming, wherever public opinion had unequivocally declared itself, to find that he had to perform the function of reversing the judgment. In philosophy his work is a good one: in the science of politics, he was against the best-established truths in physical science. From these peculiarities his attacks on the social morality of his age have been received as造成的 blows struck in a right quarter by a man who strives genuine, that the author of his 'Tableau' has thus frequently been looked on as no more the result of just observation than the censorious remarks of a universal grumbler, who, living in a brothel or a gambling-house, pretends the authenticity of this and that impropriety by which he was surrounded. But Mercier deserves a better appreciation, and none can attentively read his censure without seeing that they proceed not only from a confirmation of what is wrong, but a sense of what is right. A list of his works would be much longer than the present article. He passed a life of cheerful vivacity, surrounded by friends who seem not to have been too attached to him that he perpetually displayed with singular simplicity his sublime self-conceit. He died on the 25th of April, 1814.

MERCURLIUS, a genus of plants belonging to the natural order Euphorbiaceae, has discursive or monstrous flowers; the style short and forked in the female flowers; the capsule 2-seeded; the cells 1-seeded, bursting at the back. The species are herbs; two of them are natives of Great Britain.

M. perennis, Perennial Mercury, has a simple stem, the leaves stalked, ovate-oblung, rough; the female flowers long on common stalks; the root creeping. It is a native of woods and hedges.

M. annua, Annual Mercury, has the stem branched, leaves stalked, ovate, or ovate-oblung, smooth, the female flowers nearly sessile, the root fibrous. It is a common plant in waste cultivated lands. It once had a place in the British Pharmacopæia on account of its supposed efficacy as an emmenagogue, but it is not now used for that purpose. The leaves abound in magnotious matter, and are cooked and eaten in Germany in the same way as we eat spinach. Professor Burnett has pointed out the peculiar instability of the stamens of this plant. At the period when they are fully developed, they are touched by the flower, the flowers are forced into buds, and, being then forced inwards, have their stipules, and, and voilâ elliptically towards the pistillate flowers.

[Burnett, Outlines of Botany; Babington, Manual of British Botany.]

MERCURY, DEPRESSION OF. [Depression of Mercury, P. C. S.] MERIAN, MATTHEW, a very distinguished German portrait painter, was the son of the eminent engraver of the same name. He appears to have been born at Antwerp in 1621. He was the pupil of Sandrart, who was much attached to him; he studied also after Vandyck in London; became acquainted with Le Sueur and Voset in Paris,
and studied under Sacchi and Carlo Maratti at Rome. From about 1730 to 1750 he was the chief print-engraver in his father's book and print business, at Frankfurt on the Main, but he did not give up his own profession. He painted the Emperor Leopold I. on horseback, and many other German and other statesmen and statesmen of historic persons, and engraved a few plates, which are marked M. Merivan, junior. He died at Frankfurt, in 1837.

Matthew's sister Maria Sibylia Merian was an eminent in- scence of watercolor painter. She died at Amsterdam in 1717, aged seventy.

---

MESMERISM. [Animal Magnetism, P. C. S.]

MESOLONGHI or MESOLEO'NGI, perhaps the ancient Olene, Όλενη, in Aetolia, a small town in Greece, lies on the northern side of the Gulf of Patras, near its entrance, and right opposite Cape Kologria or Papas in the Morea. It became remarkable during the last Greek insur- rection against the Turks, as is stated in the life of Bozjariz in the Greek letters, and the character of it by Ibrahim Pasha, the commander in chief of the besiegers. The heroic resistance of the Greek garrison, and their ultimate fate, made the name of Mesolonghi popular throughout the world.

Mesolonghi is built on the edge of a marshy plain, bounded on the north by the high ridge of Zygos, the ancient Arseny- thus, and is protected towards the sea by a lagoon extending across the Gulf of Patras, which is cut into the land, and encloses the Vassiladi, on which the Greeks had built a small fort; and by the sea, by the town of Anadotiko. At the time of the outbreak of the Greek revo- lution the town contained several thousand inhabitants, who derived wealth from their extensive fisheries. The fortifications were in such a state that the allied fleet of the Greeks to strengthen the place by additional works; but the Turks left them only time to add a rampart of earth faced with stones, and a ditch, which surrounded the town on the land side. The enemy, under the Turkish commander in Northern Greece, in the beginning of 1825, many Greek palikars and others flocked to Mesolonghi with their families, so that the garrison was increased to about 5000 fighting men. Their provisions were reduced, and the town was invested and bombarded by the Turks, under the command of General Lord Byron, of the 2nd of August, 1825, Reshid Pasha appeared in sight of the town, with an army of 20,000 men and a numerous battering train, to which the besiegers could only oppose forty-eight bad iron guns of calibre varying from 4- to 48- pounders, two brass 10-inch mortars, one howitzer of 5 inches, and one mountain howitzer of 4 inches. The Turks made the first breach on the 5th of May, and on the night of the 11th of June, the great bombardment began. Bombardments and stormings now succeeded each other during two months, but the fire was well answered from the rampart, and the Greeks made frequent sallies, in which the besiegers were almost always defeated. In the beginning of July, the Turks found their 2nd howitzer of 48 pounds, and the Hydriot village lying at the entrance of the lagoon, to be occasion of many evacuations and provisions in the town, till, on the 10th of the same month, the great Ottoman fleet appeared off the place, and, after having obliged the Hydriot to avoid a certain defeat by a hasty retreat, landed a strong body of Turks, under Husein Bei. On the 28th of July, the 2nd of August, and in the night of the 3rd, the fortress was furiously assailed, and a terrible and complete deli- cation destruction among the houses and their inhabitants; but the Greeks stood their ground, and were excited to hopes of certain victory when, a few days afterwards, the great Greek fleet under Moulis and Sakhtouri came in sight, and after a severe conflict defeated and dispersed the Turkish fleet. The maritime blockade was now at an end, and in the beginning of September the garrison was still 4000 strong, with an ad- ditional population of 10,000 women, children, aged and infirm men. Reshid Pasha, however, was far from being discouraged, and resolved upon still more vigorous attacks; but Sultan Mahmud, who was bent upon the possession of Mesolonghi, gave orders to Ibrahim Pasha, who commanded in the Morea, to take the chief command, while Reshid Pasha was to act as his first lieutenant.

The Egyptians General moved northward, and towards the end of November the combined fleet of Turkey, Egypt, and Barbary, drove the Greek fleet from the lagoon, and kept a strict watch over its entrance. During the whole of the months of December and January, the Greeks were com- pletely cut off, and they made some sorties and noted the Greeks to make an attack. In the beginning of the month of January, the Greek fleet was cut off, and the garrison continued to be kept in constant danger of starvation they would not capitulate, and continued their deadly sorties, when at last, Ibrahim, after having taken the islands of Poros and Anadotiko, made the town a heap of ruins by an unrelenting and perfect destruction of the whole town, and a few months after the date of the fall of the fortress, Ibrahim Pasha appeared in the Egyptian camp, and they might have escaped with their families without incurring great risk of being either...
driven back within the fortress, or mass prisoners while in the midst of the enemy's army. Their ammunition and food being completely exhausted, so that even cats and rats were devoured with avidity, the garrison resolved to cut their way through the Egyptian defiles and effect a retreat into the neighbouring mountains. According to the best authorities the population consisted, in the month of April, of about 6000 persons. Three thousand fighting men were to rush headlong from the besieging army, and, when the heroes of Mesolonghi appeared outside their shattered stronghold, they were suddenly surrounded by the main body of the Egyptians. A dreadful conflict ensued. Five hundred men were cut down by the infuriated besiegers; 1800 persons, of whom 200 were females, escaped, of whom, however, 600 were starved to death in the mountains; and Ithobal boasted of having taken prisoners 3000 soldiers, and from 3000 to 4000 women and children. Many of the captives were afterwards ransomed through the exertions of the Philhellene societies in Europe. Nothi-Bonzaris and Mitcho-Koutyiani, though both upwards of seventy, escaped safely. Among the slain were Joseph Frat, the chief merchant of the town, Tony Papedizopulos, the General Stourazia, Sadimus, and many other Greeks of note. Among the Germans, Baron von Riedesel and Lieutenant Rosier were killed during the siege; Colonels Dillois and Delaunay, Captains Baron von Glinow and Stelzberg, Lieutenant Kneckl and Schiap, and several other gentlemen fell in the sortie. With them remained on the battle-field Dr. Meyer, another German, who was the editor of the "Greece," and among the men who was equally enraged with his pen and his sword: his wife and children were dragged into slavery. 'History will do us justice' wrote the gallant doctor, a few days previous to the last sortie, to a friend and parent. 'The defeat of our countrymen. My relation have drawn up of the siege survive me.' This relation was unfortunately lost.

Thus fell Mesolonghi after a siege of twelve months, and after 100,000 shot and shells had been exchanged between the besieged and the besiegers. Its melancholy fate excited the sympathy of all Europe, and there is scarcely a modern language in which poems were not written on the heroes of Mesolonghi.

(Gordon, History of the Greek Revolution.)

MESOPOTAMIA (from the Greek μεσός, 'middle,' and ποταμός, 'river'), the country between the two rivers, is a term which includes part of the Greek and Babylonian Mesopotamia (Strabo, and others) to comprehended all the countries which lie between the rivers Euphrates and Tigris, and it is still in use. The Arabians call this country by the corresponding name of Al Jawf, and the citizens of the towns and cities which are situated in the political division, geographers do not agree as to the extent of the countries to be comprehended under this name. Some confine it to the country itself, or those lying between 35° N. lat. and the Chalda or Median Wall (34° N. lat.), whilst others extend it northward to 40° N. lat., or the sources of the Euphrates, and southward to 30°, where the Tigris and Euphrates unite. We shall here give a description of the countries included between the parallels of 40° and 30° N. lat.

When a traveller departing from Trebizond or Rizhik, on the reverse of the Black Sea, directs his steps southward, he passes over several mountain ridges running east and west, and is soon aware that the country rises rapidly. About seventy miles from the sea he finds himself on the mountains, which is an indication that a retreat into the plain of Asia from east to west, and which in antient times went by the name of the Taurus and Antitaurus. This northern chain is traversed in its length by the parallel 40° N. lat. As it is called Northern, it is always covered with snow, and many summits are 18,000 feet above the sea-level. From these mountains the view ranges southward over an elevated table-land, that of the Frat extends southward and westward the highest part, and whose surface varies from 3000 to 6000 feet above the sea-level, but several of the mountain masses attain 10,000 feet. On the south of it, between 38° and 36° 30', lies the hilly region of Mesopotamia, or the subsidience region of the Taurus. The country here sinks gradually from 2500 feet to 1000 feet and less above the sea-level. It is succeeded on the south by the great desert plain of Mesopotamia, which embraces all the countries between the two rivers, or between 36° and 34° lat. This region is separated from the low plain of Babylonia by the Chalda or Median Wall, which begins on the banks of the Tigris, near 34° N. lat., and it terminates on those of the Euphrates, near 33° 30' N. lat. This important water-course divides the country, and is the most conspicuous feature in the whole region. It encircles the fourth region, the plain of Babylon, or of Iraq Arabi.

1. The table-land of the Frat and Murad lies between 40° and 38° N. lat., and between 36° and 44° E. long. In width from north to south it extends about 100 miles, and in length from east to west about 250 miles. This gives an area of 25,000 square miles, or somewhat less than that of Ireland. It constitutes the most elevated portion of the high grounds by which the table-lands of Asia Minor are connected with the great table-land of Iran or Persia. The elevation of this table-land varies greatly. The highest part is in the north-east corner, where the lowest part of the country is about 6000 feet above the sea-level. Hence it descends rather rapidly along the banks of the Frat or Karu-su, for Erzerum is nearly 6000 feet, and Erzinjan probably not more than 4000 feet, above the sea-level; where the Frat meets the Murad the elevation is less than 3000 feet. The descent along the Murad river is somewhat less rapid, as the highest point on the table-land near Chalid is near as at sea; at Falu the level of the river is 2819 feet above the sea.

This table-land has a very unequal surface, but the inequalities constitute large masses. The Kop Dagh, which forms the northern part of the table-land, is elevated to a height of 10,000 feet. Its northern face, or that which looks towards the Black Sea, is well wooded, but on its southern declivity there are no forests. Another mountain-chain, called the Khazar Dagh, extends the table-land on the south. It begins on the coast with the Nimrud Tagh, a high peak west of the Lake of Van, and rises above the snow-line and more than 10,000 feet above the sea. Hence the Khazar Dagh and the mountains of the Nigor form a great table-land, where the Euphrates makes its great bend opposite the town of Matalayik. Towards the east this range rises from 7000 to 8000 feet above the sea-level, for the mountain-passes which traverse it are from 6000 to 7000 feet high; but it appears to be lower towards the west; and that portion of it which surrounds the source of the Tigris is only 5000 feet high. This appears also to be the general elevation of this mountain-mass where it comes close to the bed of the Euphrates, where this river forms its three hundred cataracts between Isgolu or Fizoglu and Gerger. No mountain-range forms the borders of the table-land on the east, where it extends almost on the parallel 40° N. lat., as the parallel 60° E. long. that marks the source of the Murad the Ala Dagh rises above the snow-line, and it appears to be an isolated mass. Much farther to the west, and at nearly equal distances from the northern and southern borders of the table-land, there are two other great masses, of which the eastern is called Bingol, Tagh, and the western Dujik Tagh. The declivities of the last-mentioned range approach the banks of the Frat above its confluence with the Murad. The two mountain-masses are probably separated from each other by a wide depression, and both rise above the snow-line. These parts of the region which are always covered with snow do not appear to cover a considerable space, but from their declivities mountain-streams descend, which are always copiously supplied with water. This circumstance, united to the general gradual rise of the table-land, makes this one of the best-watered regions in Asia; and the whole surface, with the exception of the most elevated parts, may be turned to useful purposes. The largest portion of the region, as regards the extent of the surface, is rated the great mountain-mass, especially in the countries which are separated from each other by a wide depression, and both rise above the snow-line. This mountain-mass is a great chain of mountains, and is divided into two main masses: the northern ranges extend almost east and west, and the southern ranges have a northerly direction.
The surrounding country is very fertile, and considered the most populous portion of the table-land.

II. The Hilly Region of Mesopotamia, or the Subalpine Region of Mount Taurus, lies to the south of the Kzarzan Tagh, from which it is separated by the lower declivities of the mountains which enclose the valley in which the Murad river runs, that forest occurs, and even there they consist only of underwood, especially willows and dogwood.

But a considerable portion of this region is fit for agriculture. The rivers do not always run in narrow valleys, but frequently traverse depressions, which on account of their extent may be called plains, and extend from forty to forty miles long, and from ten to twelve miles wide. Such are on the banks of the Frat, the plains of Erzerum, and Erzincan, and on those of the Murad, the plains of Mshh and Kharapat, and a number of smaller plains. Near the banks of the rivers these plains are usually swampy, but in general they possess a considerable degree of fertility, except some of the higher grounds, which only yield abundant crops in wet seasons. These plains differ greatly in elevation, and consequently in climate and productions.

The Plain of Erzerum and some smaller districts in its vicinity are nearly 6000 feet above the sea-level. The winter is long and cold, commencing in the beginning of November and continue to April. Snow sometimes falls in the commencement of June, and the corn is gathered in September. But during the summer months the heat is excessive, the weather is dusty, and few places are found necessary to irrigate the fields. The plains of Northern Europe grow very well, and yield rich crops, especially wheat and barley, but only a few of the harder fruit trees are cultivated. The tame and domesticated animals are very numerous, and the sheep of uncommon size. The plains of Erzincan, Mshh, and Kharapat, are about 3000 feet lower. Though the winter here lasts four months, the heat is much more favorable to the growth of many plants and trees. The corn is ripe in the month of July, and the orchards and plantations of trees are numerous. Grapes and melons are extensively cultivated, and the fruit of the mulberry-trees is held in great esteem. These advantages, united to the extensive pasture-grounds on the higher portions of the table-land, have rendered these plains the abode of a numerous population. This region is politically divided into two pashaliks, those of Erzerum and Mshh, and contains several populous places. The most important of them are the following:

Erzerum. [ERZERUM, P. C., vol. x., p. 8.]

Erzincan, on the Frat, is built on an extensive well cultivated plain, on which there are about one hundred villages, and inhabited by 3000 families, or about 18,000 individuals. The corn, which is the staple article of food, is of a very fine quality.

Egin is in a rather narrow valley, between steep mountain masses rising to 4000 feet above the Frat, whose declivities, however, to a considerable height are covered with orchards and plantations of trees. The number of the numerous villages in its vicinity is from 400 to 600 families. The valley is too narrow to admit of cultivation on a large scale, and the population, which is great, lives almost entirely on the fruit of the white mulberry-trees, which here, as in some parts of Afghanistan, is dried and used as bread.

Kebkan Maaden, on the Euphrates, a mile and a half below the place where the Frat and the Murad rivers unite, is built in a ravine enclosed by bare mountain masses. It owes its existence to the silver-mines in its vicinity, but they are not very productive. The population consists of between 400 and 500 families, all of them engaged in mining.

Jesr (Jesir) is a well situated inhabited plain, has 8000 inhabitants, who are partly engaged in manufacturing iron utensils, carpets, stockings, and linen-cloth. It has some commerce with Erzerum, Bithia, and Diarbekir.

It is situated about 475 feet above the level of the Murad river, which washes its base. It contains about 1000 families, some of which are engaged in weaving coarse cotton-cloth, for which there are 200 looms, and others in dyeing and finishing them. The valley is bordered by orchards. About twenty-four miles east of Palu, and about two miles from the southern banks of the Murad river, are the iron-mines of Sivan Maaden, where the mineral is very abundant, and the ore is of a very soft and easy quality. The Turks began to work the mines some years ago. Kharapat is built on a cliff rising 1000 feet above the adjacent plain, and contained in 1835 about 6000 individuals.
MES 288

... during the wet season, and until the grass is dried up by the heat. In some parts the surface is bare of mould and consists of naked rocks. There are no trees on this plain except mulberries and apricots, which are planted in some places. Corn and barley are grown, and some cotton, and also maize. In the vicinity of the town of Diarbekr cultivation is carried on with more vigour: flax is also grown.

... in the southern hills of the Tigris, where the river runs from west to east, the plain is bordered by rocky masses, which rise with rather a steep ascent to 2000 feet above the general level of the plain. Though they appear nearly continuous, these masses consist of the border of a table-land which occupies the whole country between the Euphrates and Tigris, north of 37° N. lat. and compels the Tigris to run eastward and the Euphrates west; north of about 40° N. lat. they are widely separated; but sixty miles farther south, between Rumkalah on the Euphrates and Jezirah Ibn Omar on the Tigris, they are more than two and a half miles from each other. The highest part of this table-land runs from north-west to south-east, beginning at no great distance north-east of the town of Severceck and terminating with the hill on which the town of Martin is built. This ridge appears to be properly called Marja Daglieri. This region has no watercourses, though a considerable quantity of snow appears to fall during the winter months. This must chiefly be attributed to the limestone, of which, according to Ainsworth, the surface of the country is composed, which quickly absorbs all the water. Where this is the case the country generally presents bare rocks, or only a very scanty vegetation during the wet season. This consists of a fruit of plants which are common to the basin and trap, and these have a soil fit for cultivation, or at least good pasture-ground. The whole country is imperfectly known, especially the portion contiguous to the Tigris, which has been visited by European travellers only in the vicinity of the river. Where the bed of the river is narrowed by the mountain-masses advancing to the water's edge on the east from the mountains of Kurdistan, and on the west by the Karaja Daglieri, the surface of the table-land is most broken by valleys and ridges, interspersed here and there with elevated plains. The valleys are well cultivated, and produce wheat, rice, cotton, tobacco, cucumbers, and melons; some of them have good vineyards. The ridges are well covered with oak, pine, holly, elm, and several bushes. The plains afford good pasture-grounds, and are also partly cultivated.

... farther inland the country appears to be more uneven, as the inhabitants are able to defy the Turkish government and to maintain their independence; but according to the accounts of the natives there are many fertile valleys in it. If their accounts deserve credit, the eastern districts are much more fertile than those west. The whole country is very dry. The summer is so great that nearly the whole is a desert, with the exception of some depressions, whose surface is formed of trap or basalt, and where a few villages occur with some cultivation. In the northern part of the Euphrates where the mountain-masses have sunk down to 1200 or even 800 feet above the level of the river, the edge of the masses is split and indented, and numerous small valleys are here crossed by high ridges. Some of these valleys are fertile, but the largest part of them is covered with ochards, consisting of olives, pomegranates, mulberries, pears, peaches, and quinces; all of them have also excellent vine plantations. In some parts cotton is cultivated.

... the country through which the caravan-road between Bir-eh-Jik and Mosul runs, has great variety of soil and soil. Between Bir-eh-Jik and Urfa it is hilly, and contains many cultivated tracts. Farther east, as far as Martin, culturing and wooded tracts, mostly situated in depressions, or valleys alternate with plains, in which some cases afford pasture, and in others are quite sterile. This tract is very uneven, and the surface is broken by numerous small valleys and hills, with the river of a conical shape. These ridges continue to Nishin, but are less frequent. Between them run some watercourses, which are used for irrigation, and soon lost in the desert country south of Urfa. At Erebis the season is very dry, but as in this part there are numerous watercourses, the adjacent country has pasture even during the summer months. After having passed Tel Rumaklah the road leaves the HillyRegion and enters the desert.

... this region has a more temperate climate than the table-land of the Frat and Murad, on account of its less elevation, the mountain-ranges which surround it on the east, north, and west, and its more southern stations, but the private is much colder than that of Europe in the same parallel, because it lies much farther from the sea, and does not receive the warm western winds prevalent on the Mediterranean, as the elevated country is exposed to a different direction, and prevents them penetrating so far eastward. The thermometer has been observed to descend as low as 12° of Fahrenheit. In January and February a great quantity of snow falls. The spring hardly ascends to 30°, and in July sometimes descends to such a height as hardly any rain falls to the end of October, or the commencement of November. The thermometer rises to 50°, and all grass and minor vegetation dries up. Pasture is then only found on the higher and level places. Water is very common in many places of the table-land. Nature becomes resanned in the month of November, when the Nide clouds appear, which proceed from Mount Lebanon eastward, and bring to the country very heavy rains, which about the beginning of the year are changed into snow.

... If the Plain of Diarbekr is excepted, agriculture is limited to some tracts of moderate extent, to the numerous but narrow and short valleys, and a few plains and depressions which have a fruitful soil. The cereals which are grown are wheat, beans, barley, rice (in very few places), lentiles, cicer arsituinum, Lathyrus sativus, vicia hispanica, phascolus maximus, durra (holcus orghanum) and medicago sativa. Other vegetables are several kinds of cucumbers, melons, solanum melongena, ribes, cucumis esculentus, and pumpkins. The orchards and plantations consist of olives, figs, pomegranates, pears, quinces, cherries, peaches, pomegranates, melons, figs, cherries, American plums (Prunus american), three other kinds of plums, apples, pears, quinces, cornelian cherries, almonds, walnuts, hazel-nuts, chestnuts, and cumbra kernels (the tree which has been so much abused by Ainsworth). The wild vegetation consists of castor-oil (ricinus communis), hemp, flax, saff (cannabina tinctoria), cotton, and trigonella foenum graecum are also cultivated. Among the wild plants are capparis spinosa, mustard (sinapis orlando), liquoress (glycyrrhiza glabra), asparagus, and arum coilocacine; the leaves of the last are used as paper.

... Sheeps, goats, and goats constitute the wealth of the nomadic tribes. There are thousands of sheep, the Tartaric, with the fat tail, which often weighs fifteen pounds, and the Arabian, whose tail is not much thicker than that of our sheep. Horses are numerous, but not so good as in the table-land of the Frat and Murad, or on the desert plain: asses are also kept in great numbers. It does not appear that camels are bred, but they are used on the caravan road.

... The most common wild animals are wild boars, deer of two or three different kinds, wolves, foxes, hares, jackals, bears, polecats, martens, marmots, hamsters (cretius vulgaris), squirrels, porcupines, and hares. There are several kinds of vultures, falcons, and owls; ravens, crows, jackdaws, thornbills, and various small birds. The chemical minerals in the Turkish rivers, the Euphrates and the Tigris, and in several of their confluents. There are also several kinds of turtles, snakes, and lizards.

... The Eil Bey Region of Mesopotamia constitutes the pashalik of Diarbekr; but the most south-eastern districts are sometimes placed under the pasha of Mosul. The most remarkable places are situated either in the Plain of Diarbekr or along the river coast between Kir-eh-Jik and Mosul. In the Plain of Diarbekr are Diarbekr. [Diarbekr, P. C., vol. viii., p. 477.]

... North of Diarbekr, on the southern declivity of the Kharaz Tagh, are very rich mines of copper, in which vicinity are two towns, one of which is called Arghana (or Arguma) Maden, and the other Madan Kapur. Arghana Maden is built about the summit of a high hill, 2887 feet above the sea-level, and contains some 800 houses, and according to others 600 houses. The declivities of the hill are partly cultivated with wheat and cotton, and partly planted with orchards and vineyards. The proper mining town, which is called Madan Kapur, is situated 14, or 15 miles distant from Arghana Maden, in a district destitute of vegetation, and contains about 4000 inhabitants, all of whom are employed in the mines. The produce of those mines formerly amounted to 400 tons, but in the last two years, on account of modern improvements, has been nearly ceased; but as in this part there are numerous watercourses, the adjacent country has pasture even during the summer months. After having passed Tel Rumaklah the road leaves the Hilly Region and enters the desert.
Kharun Tagh, is the town of Ilijeh, which contains 1000 families, and where some cotton-stuffs are manufactured: in the neighbourhood maize is cultivated.

At the eastern extremity of the Plain of Diarbekr, within the Kharun Tagh, in a very alpine country, is the town of Bitlis, 5000 feet above the sea-level, which contains 12,000 inhabitants, and carries on an active commerce with the adjacent countries and with Persia. It exports wool, tobacco, galins, and gun trussaand, which are the produce of the country, and is the cotton for the manufactures of the town, which appear to be numerous; it has also several dyeing-houses and distilleries.

Some builds near the northern extremity of the Plain of Diarbekr, not far from the base of the mountains of Kurdistan, 2750 feet above the sea-level. It contains about 5000 inhabitants, many of whom are engaged in dyeing red the cotton-stuffs of Bitlis and Ilijeh.

Along the caravan-road are the towns of Urfa or Orfa, Mardin, and Nisibis. Urfa (the antient Edessa), is the most western, is at the base of a hill, and is a well-built large place, which is frequently compared with Damascus. It is surrounded by high and strong walls, seven miles in circuit, and has between 40,000 and 50,000 inhabitants. It is not said that any branch of industry is carried on. The most remarkable object in the town, and on the western moorings, which is in its exterior and interior exhibits a considerable degree of magnificence. With this building are united several medresses, where a number of young men are instructed in the sciences.

Mardin, which is nearly at equal distance from Bir-eh-jik and Mosul, is built on the summit of a steep limestone hill, which may be considered as the termination of the Kbraska Desert; its town is 1000 feet above sea-level, and it was also stated to be the case with the valley in which the Khabur river runs southward and south-westward until it reaches the Euphrates, near the castle of Rehabeel, after a course of probably two hundred miles, and by a vast depression of about 300 feet, bounded on the east by the mountains of Tagh, and on the west by the hills of Makhul, and Saruj, and covered with a large portion of alluvial land, and to be equally fertile. The degree of fertility of the Abd-al-aziz Hills is not known, nor their extent and direction.

We are totally unacquainted with the tract between these hills and the Sinjar Hills, except that nearly all the upper branches of the Khabur river rise in this tract, and this leads to the presumption that this tract is well watered, and that it contains a fair proportion of land fit for cultivation. It was also stated to be the case with the valley in which the Khabur river runs southward and south-westward until it reaches the Euphrates, near the castle of Rehabeel, after a course of probably two hundred miles, and by a vast depression of about 300 feet, bounded on the east by the mountains of Tagh, and on the west by the hills of Makhul, and Saruj, and covered with a large portion of alluvial land, and to be equally fertile. The degree of fertility of the Abd-al-aziz Hills is not known, nor their extent and direction.

The country between the caravan-road and the Sinjar Hills is nearly a level plain, which even at the end of the dry season is mostly covered with coarse grass and prickly plants. In some places there are tracts of marshy ground, with many long reeds, and interspersed with many large pools of sweet water; but at some places the soft soil is impregnated with salt. There are in this part many conical hills from 80 to 100 feet in height; they are red and reddish, and are broken by some. The portion of this tract which is under cultivation is small.

The Sinjar Hills run east and west with a slight inclination to the south. They extend in length about fifty miles, and in breadth from seven to nine miles. The highest part of the hills is near the eastern extremity, where they rise about 1500 feet above the plain. This is an agricultural district. Considerable quantities of wheat, barley, and cotton are produced in the lower and more level parts, and the sides of the hills are covered with plantations of fig-trees and vines, which yield articles of export. A portion of the hills is covered with oak trees, the acorns of which are gathered in large quantities, together with the numerous wild boars which frequent the hills. The number of the inhabitants, who are Yezidis, is stated to exceed 6000.

The plain between the Sinjar Hills and the Tigris has an undulating surface, and is for the most part barren, and covered with coarse scanty grass and thorny shrubs; there are large tracts of barren marshy land, strongly impregnated with saline matter. The most common vegetable production is an oat-grass, which at many places covers tracts of several miles in extent, to the exclusion of all other plants, except a few flowers. Cultivation is only carried on in some of the beds of temporary watercourses, and between some low ridges of rocks, where wheat and barley are cultivated. Some tracts are covered with wormwood. In the vicinity of the Tigris the cultivated tracts are more extensive, not on the higher grounds, which collection is greatly hindered by a rather steep ascent of 500 feet from the plain to the hill, which is above the level of the river, but in the bottom of the Tigris. This river flows here in a valley from eight to ten miles wide: the projecting headlands of the higher country form large emplacements called "Alums," which have been traversed by the Tigris, grown in their natural state with grass and small tamarisks, but where cultivated giving abundant crops of grain or rice. In proceeding from Mosul southward the cultivated tracts descend above the level of the river, and in the bottom of the Tigris. This river flows here in a valley from eight to ten miles wide. The projecting headlands of the higher country form large emplacements called "Alums," which have been traversed by the Tigris, grown in their natural state with grass and small tamarisks, but where cultivated giving abundant crops of grain or rice. In proceeding from Mosul southward the cultivated tracts descend above the level of the river, and in the bottom of the Tigris. This river flows here in a valley from eight to ten miles wide. The projecting headlands of the higher country form large emplacements called "Alums," which have been traversed by the Tigris, grown in their natural state with grass and small tamarisks, but where cultivated giving abundant crops of grain or rice.
the banks of the Tigris from the south-east. The Jebel Makhlul may rise about 600 feet above the level of the river: it consists mostly of two ages, and is composed of one mass of truncated cones. It is a waste land. At its western base is a large tract of country with a sandy soil, which contains a great number of hither wells that are frequently visited by the nomadic tribes of the Arabs. The banks of the Tigris, between Jebel Makhlul and the town of Tekrit and a few miles to the north of it, are uninhabited on account of the neighbourhood of these tribes. Between Tekrit and the Median Wall the alluvial tract on the banks of the Tigris grows much wider, and appears to have been formerly well cultivated. This tract was interrupted by a large canal which still exists under the name of Ishaki, and extends from the town of Tekrit to Bagdad; a great number of smaller canals of irrigation are connected with it. There are no large rivers, except the Tigris, in the season abundant for pasture for buffaloes and horses. The number of islands in the river decreases, and they are no longer cultivable; their soil consists of sand and mud. Such is the country between Hit and the Median Wall.

The Median Wall runs from the banks of the Euphrates to those of the Tigris. Its southern extremity is said to be on the Euphrates, a few hours above Feliubah; but at this point it has not yet been recognised by European travellers. Its northern extremity is found somewhat north of 34° N. lat.; so that it runs in a straight line from N.N.E. to S.S.W. It is an embankment or wall, 40 paces thick, and towers or battlements. It extends along the whole of the wall and on the side it has a deep ditch, 27 paces broad. Near the Tigris it is built of the small pebbles of the country, and near the Euphrates of a pebbly and cement of lime of great tenacity. It is from 30 to 40 feet in height, and is probably 500 years old. It is built of bricks, and in some parts went down level with the desert. According to their tradition it was built by Nebuchadnezzar (Nimrud) to keep off the people of Ninuwa (Nineveh), with whom he had an unpleasant war; and they call it Suid Nimrud, or Chalû (embankment).

Our knowledge of the climate of this region is limited to a few general notices. The heat in summer is very great, and no rain falls up to the middle of November. During November and December the rain falls in frequent and heavy showers, but is not continual. In January and February there is a good deal of frost, and after the spring has commenced in March the heat begins to increase. It is generally hot in the middle of June, and in the month of July the heat of the desert is sometimes endured. But every effort of man is opposed to the raising of crops between Hit and the Tigris; and the swamps are either overgrown with tamarisk-bushes or used as pasture-ground. There is hardly any cultivation. In these parts the bed of the river is wider, and there are several islands. A few date-trees are planted.

At the mouth of the Khabur river some extensive woods, composed of high trees, especially tamarisks and palms. Lower down the low and level flats increase in extent, and here also cultivation is much more attended to, but still by far the greater part of the bottom is swampy, or only used as pasture. The number of islands increases as we proceed farther south; they are partly bare and partly wooded with tamarisks. As we reach the banks of the Tigris, the vegetation begins to be more general. Round this place a large tract is well cultivated; corn, cotton, French beans, and sesame are raised to a great extent; the plantations of dates are extensive, and the numerous orchards yield oranges, lemons, pomegranates, figs, and olives. The olive-tree is not met with farther south; but the other trees and branches of agriculture are greatly attended to in the bottom of the Euphrates as far down as Hit. The alluvial tract of land is very extensive. There is great state culture, and is richly surrounded by plantations of date-trees; and between them and the low, rounded, gently sloping hills at the back, the bottom is, with the exception of some swampy ground, in a high state of cultivation, and full of fertility. It is mainlly to this, which is ascribed to the system of irrigation which has been introduced.

A great number of canals traverse the river bottom in its width, extending from 200 to 2000 yards from the banks, and the water, raised by machines is distributed over the adjacent lands. The numerous islands which occur in this part of the course of the Euphrates are mostly cultivated, and on some of them towns are built.
made of branches from one and a half to two inches in thickness. The interstices are filled up with bark or straw, and then the whole is caulked with bitumen. In such boats the bitumen, salt, and prepared lime are taken to Hilla, Basoras, and Hadd, a distance of some ten miles, where the boats pass through the canal of Salkiwiyah. The mode of navigating the river resembles that practised above two thousand years ago. (Herodotus, i. 194.)

Between those two towns, and before the peak Arabi, extends from the Median wall (34° N. lat.) to the confluence of the Euphrates and Tigris at Korash (31° N. lat.), and between 44° and 47° E. long. In length it does not much exceed 1,000 miles, yet more than doubles that distance in breadth of water. Between Felujah and Bagdad it is not more than forty miles wide, but lower down it widens to a hundred miles. Eighty miles may be the average width. This gives to this region an area of 10,000 square miles, or less than two-thirds the extent of Ireland.

This is the Babylonian which is described by Herodotus (i. 138) as a fertile tract, and as the seat of an immense population. At present this country is a desert. But when we consider the immense space over which the ruins of Babylon are scattered, and the large tracts in the interior of the country which are covered with continuous heaps of ruins, indicating the seat of a once populous Tigris to the confluence of the Euphrates and Tigris, from each other, of the existence of which towns nevertheless not the slightest indications occur in the ancient writers or the Arabian writers of the middle ages, we must come to the conclusion that we are much mistaken in this sense of the seat of a people, who had attained a high degree of civilization, and that the famous city of Babylon was only the last of the numerous cities which successively were built there and destroyed. The civilization probably goes as far back as that of Hindustan. Its destruction is chiefly to be ascribed to its situation between the two elevated table-lands of Iran in Persia, and of Nejd in Arabia, which are not adapted for arable cultivation to any great extent, but must remain the dominion of nomadic tribes, whose character and habits make them the scavengers of cultivated countries, and the destroyers of each other's works.

Babylonia attained its high degree of cultivation by a system of irrigation. The whole region was traversed by numerous larger and smaller canals running in every direction, by which abundance of water for irrigation was supplied to every spot. This circumstance, united to a summer heat which is not inferior to that of the tropics, enabled the soil, which is by no means of a superior description, to yield fifty or sixty fold the seed. The principal canals for irrigation extend across the whole country from the Euphrates to the Tigris. They occur chiefly in the northern and southern districts, and this is evidently to be attributed to the different levels of the Euphrates and Tigris canal. The northern part of 32° the level of the Euphrates is considerably higher than that of the Tigris, and the water in the canals runs with a moderately strong current from west to east and falls into the Tigris. All the canals of the southern parts, as the ones planted by the Euphrates below Basoras, as the one from the town of Hilla to the Euphrates below Basoras, and consequently the water in the canals runs from the Tigris to the Euphrates, from north to south. The construction of these canals goes back to the remotest ages, but they have been made so substantial, that at present, after many centuries of neglect, a great number of them still impart a degree of fertility to the adjacent fields, and two of them have actually been navigated by steam-boats; it is probable that several others which are known to exist would serve the same purpose. The most northern of these canals is the Salkiwiyah canal, which runs from the castle of Felujah, and not far south of the place where, according to the accounts of the natives, the Median Wall terminates on the banks of this river, and reaches the Tigris below Bagdad. Though the direct distance between the two terminations of the canals is not more than 45 miles, its length is 70 miles, because for two-thirds of its course near the Euphrates there are many bends; the last third runs nearly in a straight line, and is frequently fifty yards wide. But where its course is not direct the canal is very narrow, so that the steam-boat navigated it with difficulty. This circumstance, the quickness of the current, which runs through it, and the necessity of its being fortified, is inferred from the position of its banks, which never rise above the level of the adjacent country, and are frequently lower. It appears to prove that this part of the Salkiwiyah is a portion of a running stream and not a canal. Near the Euphrates the banks are thickly dotted with bushes of liquorice, which grow to the height of ten feet, and have roots of considerable thickness; these roots give consistence to the soft soil of which the banks are composed. Farther on the country adjacent to the canal presents a boundless prairie, and the only objects which distinguish it from the desert are the black tents of the nomadic Arabs. By this canal the wicker-boats of Hit bring the produce of the country contiguous to that place to Bagdad, and it has twice been navigated by steam-boats. In the first place, when the river at Tigris falls into a large lake called the Hor, which lies west of the town of Bagdad; a canal about five miles long called Mosaic, carries the waters of the Hor into the Tigris. It is also navigated by steam-boats.

The Salkiwiyah is considered to be the Isa canal of Abuhelda, who mentions three other canals further south, which cross the whole width of Babylonia, and these canals still exist. They are called, from north to south, the Nahr Abu Gharib, the Nahr Melik, and Nahr Dhiya. We have no particular account of these canals. These four canals leave the Euphrates between 33° 30' and 39° N. lat. The mouths of some other canals are seen farther south, as far as the ruins of Babylon, but it is not known how far they extend inland.

The principal canal in the southern districts of the plain of Babylonia is the Shat el Hiyeh, which carries the waters of the Euphrates into the Tigris. It begins at the small town of Kut el Amara, a miserable village on the eastern bank of the river, nearly a hundred miles below Bagdad in a straight line, and 176 miles measured along the windings of the Tigris. The canal begins at the town of Kut el Amara, and enters the Euphrates nearly opposite Arje or Arbana, about fifty miles above the confluence of the two great rivers. They are joined by two canals, one that flows from the Butje-Thatar, and the eastern Sa-yid Nawain; their mouths are about five miles apart. The tide ascends the Euphrates as far as Arje. This canal is dry in summer, but during eight months it is navigable, and in winter it is 150 feet wide and rather more than two fathoms deep. In this period of the year it was navigated by a steam-boat during the last Babylonia expedition; but only the western branch is navigable, the country to the east of which consists of large settlements, and a considerable traffic is carried on it. At no great distance north of the western mouth of the Shat el Hiyeh is that of another large canal called the Shat el Kar. It runs also from north to south, but it is not known where it originates, and whether its northern extremity is connected with the Nahr Dhiya. It was crossed by Fraser at a considerable distance above its mouth, where it was from 30 to 40 feet wide, and knee-deep in summer, but in winter it is fordable only in a few places. Like the Shat el Hiyeh, it is navigated by the river boats, which are made at Hit.

The banks of the Euphrates, from the place where the Salkiwiyah canal joins the river, to the mouth of the mill, are called the town of Hilla, are of moderate height. The country adjacent to them is of indifferent fertility, and is mostly overgrown with grass, thistles, and mimous. Cultivation is limited to a small number of large fields near the river. The number of cattle, sheep, and goats is not great. It appertains to be little inhabited, and only from time to time a grove of date-trees is seen. Below Hilla the country improves greatly; a large portion of it is under cultivation, and the plantations of dates are more numerous. It is a populous country: between Hilla and Diwaniyeh a number of large villages are observed, the population of which was estimated by a traveller at 10,000 individuals.

A short distance below Diwaniyeh begin the marshes of the Euphrates, which lower down are called the marshes of Lembas or Lamul. They extend about forty miles north of the Castle of Felujah, and not far south of the place where, according to the accounts of the natives, the Median Wall terminates on the banks of this river, and reaches the Tigris below Bagdad. Though the direct distance between the two terminations of the canal is not more than 45 miles, its length is 70 miles, because for two-thirds of its course near the Euphrates there are many bends; the last third runs nearly in a straight line, and is frequently fifty yards wide. But where its course is not direct the canal is very narrow, so that the steam-boat navigated it with difficulty. This circumstance, the quickness of the current, which runs through it, and the necessity of its being fortified, is inferred from the position of its banks, which never rise above the level of the adjacent country, and are frequently lower. It appears to prove that this part of the Salkiwiyah is a portion of a running stream and not a canal. Near the Euphrates the banks are thickly dotted with bushes of liquorice,
Mesopotamia is called the canal of Yusuf (Joseph). It begins about half an hour above Diwaniyah and terminates at Graham Inlet. At its upper entrance it is seventy paces wide; at its junction with the Euphrates, it is about a mile, and at Graham Inlet, about 1,500 paces from its mouth. The length of the canal is about 23 miles, and its average depth is 12 feet. The canal is divided into sections, each of which is called a "branch." The branches are named after the month in which they are stowed. The branches are stowed in the month of November, and the water is drawn out of them in the month of January. The canal is divided into two main branches, the northern and the southern. The northern branch is formed by the confluence of the Tigris and the Euphrates, and it is called the "Great Canal." The southern branch is formed by the confluence of the Euphrates and the Shat-al-Hai, and it is called the "Small Canal." The canal is divided into three main sections: the northern section, the middle section, and the southern section. The water in the canal is drawn out of the basin of the Euphrates, and it is used for irrigation purposes. The canal is stowed in the month of November, and the water is drawn out of it in the month of January. The canal is divided into sections, each of which is called a "branch." The branches are named after the month in which they are stowed. The branches are stowed in the month of November, and the water is drawn out of them in the month of January. The canal is divided into two main branches, the northern and the southern. The northern branch is formed by the confluence of the Tigris and the Euphrates, and it is called the "Great Canal." The southern branch is formed by the confluence of the Euphrates and the Shat-al-Hai, and it is called the "Small Canal." The branches are named after the month in which they are stowed. The branches are stowed in the month of November, and the water is drawn out of them in the month of January. The canal is divided into two main branches, the northern and the southern. The northern branch is formed by the confluence of the Tigris and the Euphrates, and it is called the "Great Canal." The southern branch is formed by the confluence of the Euphrates and the Shat-al-Hai, and it is called the "Small Canal.”
beethoven of Baghdad, which is not supplied with provisions from the lands in its vicinity, but from that part of Kurdistan which lies farther north. Baghdad is indeed surrounded with extensive gardens and some fields, but they extend only a few miles from the walls, and are surrounded by an uncultivated desert. The greater part of the plain is traversed by the great canal called the Ishahi, which extends from the neighbourhood of Tekrit to the Saklawiyah canal, but is without water. There are also many other canals of smaller dimensions. Of these the most important is the Khoshuai near Bagdad there is still less cultivation. The country is quite flat, and in most parts a grassy prairie, well watered; in others, covered with extensive swamps. A few small cultivated spots appear at great intervals. Herds of buffaloes however, and the black tents of the nomadic Arabsians, are common. There are hardly two or three villages which have a permanent population. As we approach the confines of the Turks and Euphrates, nothing is seen but stagnant water, swamps, and morasses, in which single families have settled, who live on the milk of their buffaloes and the little rice that they can raise.

The interior of the Plain of Babylonia is very imperfectly known. It appears to be considerably elevated above the tract adjacent to the rivers. The northern part, or that which lies to the left of the river, is lower and undulating. The soil is composed of sand and pebbles, and in most parts overgrown with coarse grass, minnows, and thistles. The water is generally brackish. Between the higher points and the lowest, the outline of the plain is formed by the incrustations of the Saklawiyah and other canals. Further south the surface is less uneven, and the soil consists of clay covered with mud, intermixed with flint and small fragments of gypsum. In the middle is a row of sanddrills, which appear to cover a considerable space. In many parts efflorescences of nitre and other salts occur, which in some places form nearly a white crust on the ground. On the banks of some of these streams there are peculiar formations, which have been designated the Shat el Hieyeh. The number of settlements is considerable, and some of them are surrounded by fields of rice and other grain.

In the country just described occur the numerous groups of ruins which have already been mentioned. Many of them are seen by those who navigate the Euphrates in passing through the marshes of Lamlum. They appear to lie in a line, which begins at Hit Hymen in the north [BARTON, F. C., vol. iii., p. 206], and extends from north-west to south-east, terminating at the lower course of the Shat el Hieyeh. Though the country has only been visited by two or three Europeans, we are already acquainted with nine or ten of these groups. The forms such masses in that level country they are frequently taken for natural hills, until a closer examination shows that they contain a great number of pieces of glass, pottery, and bricks thrown or scattered by the wind over the plain itself. In some of them fragments of columns have been found.

With respect to the climate of this region the reader is referred to Bagdad [F. C., vol. iii., p. 270], the remarks in which article may in some measure be applied to the whole region. Its productions are enumerated in the Pashalik of Bagdad [F. C., vol. iii., p. 268]. Besides the town of Bagdad, a few places occur on the banks of the Euphrates which require notice.

Hilla is a fortified place with about 25,000 inhabitants, Arabs, Persians, Turks, Jews, Armenians, and Indians, in the midst of a number of canals, which probably part the fell. It carries on a considerable commerce with all the towns of the Euphrates, mostly in river-barges of 50 to 80 tons. The imports consist especially of rice, dates, fish, oil, coffee, cotton-stuffs, and Indian goods, part of which are re-exported to Hit and Annah.

Diwaniyeh, lower down, a considerable place, with 1600 houses, is enclosed by a wall. Numerous river-barges are regularly employed in the produce of the rich country in its vicinity to other places. This is the principle if not the only market which is visited by the nomadic tribes of Nejd in Arabia. They bring to this place cattle, horses, wool, and gum, and take in return lead, fire-arms, one of different kinds, and culinary utensils. From this place the British settlements in Hindostan are supplied with horses.

Mesopotamia is inhabited by nations of different origin. Owing to its position between two table-lands inhabited by nomadic nations, it is frequented by most of the Turks and their neighbours, and it appears that they have expelled the original population, for the greater part of the country is inhabited by people whose ancestors have settled there within the period of recorded history. Those nations which claim to be aboriginal are the Armenians and the Yezidis. The Armenians are dispersed over the table-land of the Frat and Murud, and the Hilly Region of Mesopotamia. The first-named region to the south of the Euphrates contains the Frat, which it appears that until lately these three nations were almost equal in numbers in that country, but since the last war between the Turks and Russians many Armenians have left their country and gone to settle in Georgia. In the Hilly Region of Mesopotamia the number of Armenians is small in comparison with the Turks and Kurds. They are an industrious people, who occupy themselves with agriculture, the mechanical arts, and especially with commerce, by means of which they acquire wealth, and get into favour with the ruling nation, the Turks. They are Christians of the Greek church. [AZMITIA, F. C., vol. iii., p. 282].

The Yezidis are a small nation, who exclusively inhabit the Sinjar hills, and also isolated tracts in the eastern districts of the hilly region of Mesopotamia and in Kurdistan. Though they are said to have been born for ages on this scene, the Yezidis, or Mowayah, the destroyer of the race of Ali, they are evidently different from the other nations of the country. They are of a middling size, and have a clear complexion, with regular features and black eyes and hair; their limbs are spare, muscular, and well proportioned. The hair is long and the beard and whiskers kept close short, but they are prohibited from cutting or dressing the mustachio. Their religion is a strange mixture of the worship of the devil with the doctrines of the Magi, Mohammedans, and Christians. They consider the devil as the chief agent in executing the will of God, and reverence Moses, Christ, and Mohammed, believing them more or less to be the incarnations of Satana. They adore the sun as symbolical of Jesus Christ. They have no fixed place for prayer or worship, but occasionally visit the Christian churches and monasteries, and present offerings there on recovery from sickness or escaping from danger. They are brave, hospitable, and sober, faithful to their promise, and attached to their native soil, but cruel and vindictive: they consider their proper means of support to be robbery and theft, and they treat with great barbarity any unfortunate Mohammedans who fall into their power, especially Persians. They are industrious in cultivating the soil and managing their orchards and plantations.

The Kurds are another nation, who are generally considered as an original people. It is probable that when the Armenians generally adopted agriculture, those parts of their country which were unfit for cultivation, owing to the rigour of the climate, became like the desert, and possessed by the Kurds. They adore the sun as symbolical of Jesus Christ. They have no fixed place for prayer or worship, but occasionally visit the Christian churches and monasteries, and present offerings there on recovery from sickness or escaping from danger. They are brave, hospitable, and sober, faithful to their promise, and attached to their native soil, but cruel and vindictive: they consider their proper means of support to be robbery and theft, and they treat with great barbarity any unfortunate Mohammedans who fall into their power, especially Persians. They are industrious in cultivating the soil and managing their orchards and plantations.

The Kurds are another nation, who are generally considered as an original people. They are industrious in cultivating the soil and managing their orchards and plantations.
would appear, is from time to time renewed. Many of these Arab tribes have changed their mode of life, which appears away to have been the case when the immigrating tribes were not powerful enough to occupy large tracts of pastoral ground. In such cases they selected a tract fit for cultivation, where they settled and became cultivators. There is a considerable number of small Arabic tribes in the desert plains of Mesopotamia, and they always cultivate only a small tract of ground. The more powerful tribes took possession of extensive tracts of land, and cultivated them as fit for settlement. The cultivation they converted it into pasture-grounds for their horses, camels, and sheep. Some of them have preserved their nomadic habits to the present time, the especially the case with the powerful tribe of the Shammar, which is found, but the principal seat of the last-named tribe is in the desert which extends from the Euphrates to Damascus. The cultivated tracts of the desert are in possession of some smaller Arab tribes, who are tributary to the Shammar. Other Arabic tribes have been compelled by the physical nature of the country occupied by them to change their mode of life. This is most conspicuously the case with the tribe of Kaselal, which inhabits the marshes of Lamul. This region does not afford pasture for camels, horses, or sheep; it is however fit for buffaloes, for the cultivation of rice, and plantations of date-trees. The inhabitants of this region have been compelled to adopt the habits of the occupants of swamps, but they have preserved their activity and their spirit of independence. The numerous tribe of the Montefci occupies the land in the region of the Tigirs, which is almost entirely on the produce of their herds of buffaloes, cultivating occasionally a small spot of rice-ground. On the Euphrates the habits of the Montefci are much more agricultural; the date-plantations, the oases, and the furnishing of their wealth, but poorer classes have not yet entirely got rid of their nomadic inclinations, as they still prefer to pass their time with their herds of horses and sheep in the interior of the country, whilst the poorer portion of them cultivate their rice-fields and manage the date-plantations. Travellers however observe that both the fields and plantations do not exhibit that careful cultivation which is observed in other parts of Asia where the habits of the people are entirely agricultural.

It would be an almost endless task to enumerate the political changes to which Mesopotamia has been subject since it was named in history as the birth-place of Abraham. There is no part of the globe on which such changes have been so frequent and so great. From the sway of the kings of Babylonia Mesopotamia passed successively to that of the Assyrians and Medes, and then it was subjugated by the Persian and then the command of Cyrus. After the battle of Issus it fell into the power of the Macedonians, and after the death of Alexander his generals Antigonus and Seleucus successively got possession of it. Seleucus founded the kingdom of Syria, of which Mesopotamia formed a portion, until the countries belonging to the Syrian kingdom were divided between the Romans and Parthians. During many centuries Mesopotamia was the theatre of the wars in which these two nations contended for superiority, until the Parthians were supplanted by the Persian dynasty of the Sasanides, when Mesopotamia was dismembered between them and the Greek emperor of Constantinople. But at last the Arabsians appeared, and their victory established the seat of a wide-spread and powerful empire in Mesopotamia. Since the destruction of the kingdom of Babylonia, the country had not enjoyed so much prosperity as under the caliphs; but after these princes had lost their power, Mesopotamia fell into the hands of the Turkish princes, the Seljuks and Aqbecks. About the beginning of the twelfth century a portion of it was conquered by the Crusaders, who however did not keep it long, and after the conclusion of the peace of Acre it was left to the Crusaders. The Seljuks and Aqbecks overran this part of Asia. Their progress was for a time interrupted by the famous Timur, but after his death the Osmanli empire acquired the ascendency, and subjected the whole of Mesopotamia to their dominion in the beginning of the sixteenth century. Since that time no political change of importance has taken place.

(Ker Porter's Travels in Ancient Babylon.)

**MESPLUS**, a genus of plants belonging to the natural order Rosaceae, to the suborder Pomaceae. (Pomae, P. C. S.) It has the calyx 5-cleft, the segments foliaceous, the petals nearly orbicular, the disk large, full of honey; the styles 2:5 glabrous; the pome turbinate, open, 5-celled; the endocarp bony. The species are trees, natives of Europe, and in a wild state are furnished with spines, which all disappear in cultivation. The flowers are large, nearly sessile, and white.

**M. Germanica**, the common Medlar, has lanceolate undivided leaves, downy beneath, and solitary flowers. This plant is a native of Europe and Siberia. It is found in Great Britain in hedges and thickets in Surrey, Sussex, and Cheshire. It is cultivated on account of its fruit, which is eaten in a state of decay. Its taste and flavour are peculiar, and greatly esteemed by some persons. De Candolle describes three and varieties of this species of medlar. The following are the garden or cultivated varieties:

1. Blake's large medlar.
2. The seeder, large Dutch, broad-leaved Dutch, or large German medlar. It bears the largest fruit of any of the cultivated medlars.
3. Stoneless or French medlar, has small obvolute fruit, not much cultivated.
4. Nottingham, common, small-fruited, or narrow-leaved Dutch medlar. It has an obvolute middle-sized fruit, and is the best of all the medlars.
5. Smulth, Smith's Medlar, has oblong elliptic serrated leaves, pubescent on the nerves beneath, the flowers usually solitary. The native country of this plant is unknown, but it seems to have the characters of a true species. It has white flowers, which are one-half smaller than those of the common medlar. The stipules of the sterile branches are large and foliaceous.

The medlar may be propagated by seeds or by layers, or by grafting upon seedlings of their own species or any kind of Pomeaceae. Forsyth remarks that the kinds of Medsplits do better by grafting on their own stocks. The soil best adapted to the growth of the medlar is a light and rich earth, rather moist than Koordistan, but not on a moist bottom. It may be grown either as a standard or as a quinquennal. The general horticultural treatment should be similar to that of the apple-tree. For a further account of the pomaceous genera of Rosaceae, see Pomae, P. C. S.

(Don, Gardner's Dictionary; Babington, Manual of British Botany; Loudon, Arborum et Fruticetum Brit.)

**MESSengers at Arms** are the officers who execute the writs issuing from the supreme courts in Scotland. The duty of executing the king's writs and injunctions ap-
parts to have rested with the Lyon King at arms, sided by the heralds or other assistants. To this day the Court of the Lord Lyon has authority in the admission of messengers at arms, in the impugnment of their conduct, and in their dismission from office. The Keeper has been appointed for the proper and legal performance of his official duties. Messengers require to perform their functions with great precision, as they are not only amenable to questions regarding the accuracy of their proceedings, but also to suits for the recovery of the fees set on their services. The legal accuracy of which the title to landed property may depend.

METAMORPHOSIS, VEGETABLE. [Vegetables, Metamorphosis, P. C. S.]

METEOROLOGY. [Electricity, Atmospheric, P. C. S.]

METOPTOMA, a genus of fossils ( allied to Patella? ), proposed by Professor Phillips. From the mountain limestone of the north of England.

METRODORUS, a distinguished antiquarian painter and philosopher of Athens, born about two centuries before the Christian era. "After the death of Persaeus by Paulus Emilinus, in Greece, n.c. 168, the Roman general ordered the Athenians to send him their most able painter to perpetuate his triumph, and their most distinguished philosopher to educate his sons. The Athenians paid Metrodorus the extraordinary honour of declaring to Paulus Emilinus that he was both their greatest painter and their most distinguished philosopher; and the Roman general is said to have performed the ceremony himself.

As Metrodorus was chosen to paint the triumph of Paulus Emilinus, and to educate his sons, and gave him satisfaction in both respects, we must infer that he did paint his triumph, though it is not known what of; as to the education of his sons it has been an undertaking of great magnitude, and indeed, if adequately represented, a very extraordinary performance, for in the procession of this triumph, which is particularly described by Plutarch, there were two hundred and fifty waggons containing Greek works of art: the spectacle lasted the entire day.

Pliny, Hist. Nat. xxx. 40; Plutarch, Paulus Emilinus, 32.

METROPOLIS. [Colonv, P. C. p. 359.]

METROPOLITAN. [Archbishop, P. C.]

METROPOLITAN STAGE-CARRIAGE. Before proceeding to give a brief notice of the law relating to hackney and stage carriages in London, we may quote, from two interesting papers on the 'Vehicular Statistics of London,' in 'Chamber's Edinburgh Journal' for 1845 (Nos. 76 and 78, New Series), some statements relative to such of the public vehicles of the metropolis as are not embraced in the article HACKNEY-COACH, P. C. S. These papers, we may observe, are of the highest authority. The distinction between hackney and stage carriages is pointed out under HACKNEY-COACH; and the origin of that class of stage-carriges, which has almost entirely superseded the former, is here traced. The term hackney, which has been an undertaker of great magnitude, and indeed, if adequately represented, a very extraordinary performance, for in the procession of this triumph, which is particularly described by Plutarch, there were two hundred and fifty waggons containing Greek works of art: the spectacle lasted the entire day.

The distinction between hackney and stage carriages is pointed out under HACKNEY-COACH; and the origin of that class of stage-carriges, which has almost entirely superseded the former, is here traced. The term hackney, which has been an undertaker of great magnitude, and indeed, if adequately represented, a very extraordinary performance, for in the procession of this triumph, which is particularly described by Plutarch, there were two hundred and fifty waggons containing Greek works of art: the spectacle lasted the entire day.
The length of journey run varies from about four up to twelve or thirteen miles; but by far the greater part of the London omnibuses run a total distance, from end to end of their journey, of less than eight miles. With such the usual charge is sixpence per passenger, whether for the whole or a part of the journey; but a very large portion of their receipts arises from 'short' passengers, or such as are picked up on the street. Omnibus proprietors are much exposed to peculation on the part of their servants, and various mechanical contrivances called 'tell-tales' have been tried to protect their interests by registering the number of passengers carried, but they have not proved especially useful; but in connection with the association system a method of checking the conductors, by a kind of secret police, has been adopted. When it is found that the returns made by one conductor fall short of the expected sum, spies are sent to watch him by taking his places as passengers, and reporting at headquarters the numbers taken up, as a check upon him; and so systematically is this service performed, that any attempt at deception is sure to be detected and punished by dismissal or dismissal by penalty or dismissal.

The power of applying such a check is one of the many advantages of the association system, in which, as commonly worked, each individual proprietor contributes a certain number of turn-outs (a turn-out being the technical name for an omnibus with its complement of horses and men) to a common stock, which is worked, so far as regards the time of starting, speed, and other regulations, for the common benefit. The receipts of each omnibus are then paid into a common fund, from which each proprietor receives a portion proportionate to the number of turn-outs contributed and maintained, without regard to the actual receipts of the individual, by him.

The laws which relate to hackney-carriages and metropolitan stage-carriages are chiefly comprised in two acts of Parliament: 1 & 2 Wm. IV. c. 42, which came into operation on the 1st of January, 1834. An Act to amend the laws relating to Hackney-Carriages, and to Waggons, Carts, and Drays, and to place the Collection of the Duties on Hackney-Carriages and on Hawkers and Pedlars in England under the Control of the Customs; and 1 & 2 Wm. IV. c. 50, 24th August, 1843, entitled 'An Act for regulating Hackney and Stage Carriages in and near London.'

In the former act are contained the greater part of the enactments which relate to hackney-carriages; in the latter, those which more especially apply to metropolitan stage-carriages (omnibuses).

The limits of hackney-carriages (hackney-coaches and cab-nolets) are five miles from the General Post-office, London; and drivers of hackney-carriages are compelled to drive five miles from the place where hired or from the General Post-office; but if any hackney-carriage shall be discharged at any place beyond the limits of the metropolis (that is, beyond a circle of which the radius is three miles from the General Post-office), after eight in the evening and before five in the morning, hack-fare may be charged, so long as the said limits or any standing-place beyond the limits where the carriage may have been hired, at the option of the hirer.

The fares of hackney-carriages are fixed by the act & 1 Wm. IV. c. 22. For every hackney-carriage drawn by two horses, for any distance not exceeding one mile, 1s.; for any distance exceeding one mile, at the rate of 6d. for every half-mile, and two shillings for the first half-mile. The charge for the hire of two horses is the same as that for one horse, and if the carriage be occupied by any number of two or more persons.

HACKNEY-CARRIAGES AND MANUFACTURERS, &c.

Hackney-Carriages and Metropolitan Stage-carriages are licensed by a registrar, deputy-registrar, or other officer appointed by one of Her Majesty's principal Secretaries of State; and every driver and conductor of a metropolitan stage-carriage, and every waterman, at the time of granting the licence receives a metal ticket, which every such driver, conductor, or waterman is bound to wear or exhibit, and the wearing thereof may be distinctly visible.

Omnibuses are among the assistants of drivers of hackney-carriages and of metropolitan stage-carriages stationed at certain places to supply the horses with water, &c., and they also receive a licence. A stamp duty of 6d. is charged on every licence, and 5s. is paid for it, and 10s. a week during the continuance of it. Plates are to be affixed to hackney-carriages with the name and abode of the proprietor and number of the licence; and 'Metropolitan Stage-Carriage,' or such other words as the registrar shall direct, are to be painted on omnibuses. Proprietors of metropolitan stage-carriages fix or alter their own fares, but those fares are to be distinctly painted or otherwise made known as the number of persons for whom the licence is issued.

Hackney-Carriages standing in the street, though not on any stand, to be deemed plying for hire. Drivers may ply on Sunday, but not on holidays.

Hackney-Carriages under the authority of the 'Metropolitan Stage-Carriage' Act are under a distinct system and are distinct from ordinary hackney-carriages.

The act & 6 & 7 Vict. c. 86, repeals a previous act (1 & 2 Vict. c. 79), and extends the enactments not specifically repealed of 1 & 2 Wm. IV. c. 22, to the 6th section, and to the definitions of the terms employed. Other provisions of the acts relate chiefly to the restoration of property left in carriages, tourious driving, intoxication, insulting language, loitering, and other acts of misbehaviour; to proceedings of proprietors, drivers, and conductors, as to licences, payment of duties, contracts with each other; and to modes of granting summonses, powers of magistrates, punishments, penalties, &c.

METRISIDIA: Rhus (from μητρίς, the heart of a tree, and σίδης, iron), a genus of plants belonging to the natural order Myrtaceae. It is distinguished from allied genera by the tube of the calyx not being annular, adhering to the ovary, the limb 6-cleft; the stamens 20-30, free, very long, and exerted; the style filiform, and stigma simple; the capsule 2- or 3-celled, the cells many-seeded; the seeds wingless. The species are dioecious, with opposite or alternate leaves, with the flowers pedicellate; the fruit is a berry. They are all in the genera Melaleuca and Callistemon. The last genus, with Angophora, has been recently separated from Metrissidia.

M. rura, true Iron-wood, has opposite ovate-lanceolate acuminate quite glabrous leaves seated on short petioles; the cymes axillary, pedunculate, many-flowered. It is a native of Java and Ambonaya, among rocks. The Chinese and Japanese value the wood of this tree, which they apply to many purposes, as the making of rudders, anchors, &c. for their ships and boats. The bark is used in Japan as a remedy in mucus discharges, discharges, and dysentery. It is usually mixed with some aromatic, as penang, cloves, or nutmeg.

M. polymorpha has opposite coriaceous leaves, of various forms, glabrous on both surfaces, but covered with a little silky tomentum; the leaflets thd at the summit; the leaflets terminal and axillary, corymbose; the calyxes and bracteoles glabrous or clothed with silky tomentum. This species is a tree, and grows in the Sandwiek Islands, and is said to be the plant from which it is wrong to make the clubs which the other white islands employed in warfare by the South Sea Islanders. The Akii or Libragum Vitae of New Zealand, the Rata and the Poko piano of the same country, are all hard-wooded trees belonging to this genus, and called 'rhozoioides.' (Lance-leaf Rhoea.)

Several other species of Metrosideros have been described, natives of New Holland and the South Sea Islands. M. huia, a beautiful tree, occurs as far south as Lord Auckland's Islands, and is extensive over and near New Zealand; and T. cun- dingham is the New Zealand plant called Akii, and is a rambling shrub, adhering to trees, and climbing by means of its lateral
MEY, HEINRICH, a German designer and painter, and a distinguished man in the fine arts. He was born in 1759 at Zürich, and he was for some years the pupil of J. C. Füssli there. About 1786 he went to Rome, where he made the acquaintance of Goethe. In 1787 he was at Naples, lived there in the same b&-ne with Tieckheim, and became acquainted with Herder, then travelling in the suite of Amalia, Duchess of Weimar. In 1792 he visited, for some time, Weimar, and in 1797 established himself & became the leading painter of the town. He became a great favourite with the court at Weimar, & was in intimate contact with all the distinguished literary men of the place, & held, from 1807, the office of director of the academy there, & en- joyed the titular & absolute head of the whole school. In 1818, until his death in 1832 Meyer was chiefly engaged on literary commissions relating to the history and theory of art, but chiefly the history of Greek and Roman art. He was the principal editor of the comprehensive work on the history of the sciences of Kinkelmann, which were published in 8 vols. at Dresden between 1818 and 1820 inclusive, and was the author of the greater part of the numerous notes by which they are illustrated. These note he afterwards arranged and connected into a consecutive history of Greek art, under the title ‘Geschichte der Bildenden Künste bei den Griechen,’ 2 vols. 8vo., Dresden, 1824. A third volume, being the continuation of the history of Greek art in Rome, was edited by Dr. F. W. Riemer, after the death of Meyer, under the title ‘Geschichte der Bildenden Künste bei den Griechen und Römern,’ 1 vol. 8vo., Dresden, 1836. This work, though agreeably written, and containing a good general account of the history of art, is defective in the treatment of works of ancient art, has failed to satisfy those interested in the subject, and has obtained little popular or general notice. In the first place its form is against it: the text and the author’s remarks are separated from the illustrations, while the latter are not occasionally as large as the whole pages. The text is little more than a chronological catalogue of names and works; and the notes at the end of the volumes, besides being troublesome to refer to, as disconnected with the text, do not clear up the obscurities, or reconcile the apparent contradictions of ancient authors. Reflections are rare, and when they occur they are neither profound nor illustrative, nor does he in any case indulge in aesthetic remarks, or attempt to deduce the general principles of art from the volumes. The text is little more than a chronological catalogue of names and works; and the notes at the end of the volumes, besides being troublesome to refer to, as disconnected with the text, do not clear up the obscurities, or reconcile the apparent contradictions of ancient authors. deep gorges in their sides and frequently cause landslips. The lower part of this tract contains numerous vineyards, orchards, and orange plantations. Between the two largest places of the island, Ponte Delgada, on the southern east, and the Sete Cidades, on the northern, lies the lowest part of the whole. The shores are here low, and rise almost imperceptibly towards the interior, where an irregular line of hills and craters, ending on the east, with the Fogo, 1031 feet above the sea, and terminating on the west with the Sierra Gorda, 1747 feet. The soil of this tract is in general very fertile, but there are extensive areas of light, sandy, and gravelly soil, which are only fit for vineyards. There are no hot springs or other signs of subterraneous heat, and the whole of this district is deficient in water, in consequence of its inferior elevation. The most western part of Michael's appears to be subject to volcanic changes than other parts. It contains in its centre a valley of an elliptical form, called the Cate Cidades, which is three miles long from south-east to north-west, and two miles a half broad from south-west to north-east. The ridge which bounds it is of nearly equal height throughout, except where it runs into peaks. On the south-east is a short chain, two miles long, terminating in the Pico de Carvao, which is 3633 feet above the sea. The greater part of the interior of this valley is occupied by two lakes. In this tract are two hot springs which rise up in the sea below high-water mark. The soil varies much in character, being in some places alluvial, in others morainic, well suited for cultivation and of great fertility, in others a mixture of punice and scoria, or a vitreous intractable lava which defies the efforts of man in some degree. Hot springs are frequently except in the eastern districts and the country between Delgada and Ribeira Grande.

Although the climate is variable both as to heat and humidity, it is very temperate, and the changes do not materially affect health or comfort. In summer, clouds generally float in the atmosphere and mitigate the sun's heat; in winter, there are few days when heat is not felt, and during the whole year there is not one day in which agricultural labour may not be carried on.

The mean temperature in winter is 62° and in summer 69-5°. The extremes of the whole year are 46° and 84°, in winter 46° and 76°, and in summer 66° and 84°, in February 46° and 72°, and in August 64° and 84°. A much greater proportion of vapour exists in the air in all seasons than in England. The mean annual quantity of rain is 30 inches near the level of the sea, and the maximum 42 inches, while it is probably not less than 60 inches on the mountains. The prevailing winds are from the north-east and north-west. Northerly and easterly winds prevail over those other points of the compass in the ratio of 37 to 26, which indicates that the island is best situated to part of the Atlantic where westerly winds generally prevail.

The principal occupation of the inhabitants is the cultivation of the ground. The island contains 147,200 acres, of which 21,000 are occupied by vineyards, 22,000 by orange plantations and other vineyards, and 120 acres of vegetable gardens. The arable land amounts to 40,100 acres, and the remaining 102,600 acres are occupied by mountains, lakes, rivers, roads, and dwellings. The grains which are most extensively cultivated are maize, wheat, Indian corn, and barley. The cultivation of maize and wheat succeeds in several places on the southern coast. Several kinds of vegetables are grown, but the common people cultivate only cabbages and potatoes to any extent. As two-thirds of the wheat, Indian corn, and barley cultivated, the potatoes, and more rugged portions of the island are extensive. All the domestic animals of Southern Europe are kept, but the breeds are inoffensive. Of wild quadrupeds only rabbits, ferrets, and weasels are met with, with rats and mice. There are many kinds of birds, mostly those of small size; fish is rather abundant along the shores. The inhabitants, who are Portuguese, are an industrious and peaceable people. Very few brandy or wine, and only small quantities of spirits are consumed by the individuals, are employed in agricultural labour. With the exception of the common mechanical trades, the manufacturing industry is limited to some coarse woolen stuffs, especially blankets. The industry of the coast consists of a coarse kind of red pottery, which is made at Villa Franca.

The capital of the island, Ponte Delgada, is built on the southern shore. It has an unsafe harbour, for when the wind is from the north the town is exposed. Michael's appears to have been Erebus and the Conception, with the wind to change to another quarter. The town is surrounded by extensive orchards and orange plantations, and is rather a pleasant place than a town. The population is upwards of 20,000, and it is the largest town in the Azores. Alagoa, farther east, has a small port and 4000 inhabitants; and Villa Franca, still farther east, 3000 inhabitants. In the vicinity of these places are extensive plantations of oranges and vineyards. On the northern coast is the town of Ribeira Grande, with 12,000 inhabitants. It has no harbour, being harnessed in by reefs of rocks, which run out some distance from the shore. It is irregularly built, the houses being scattered over rocky uneven ground, and forming narrow irregular streets along the coast. It has some manufactories of coarse woolen cloths and common lines.

The forest and woods are mostly confined to Portugal, but at present the island is visited by English, American, and Brazilian vessels. The number of English vessels which annually visit Michael's is about half a hundred, and about the same number sail between St. Michael's and Portugal. The American and Brazilian vessels are few. The English take only oranges, of which about 90,000 boxes are annually exported.

The other agricultural products, especially corn and maize, are carried to Portugal. The Americans take only gold and silver coin in return for their imports. The importation from England consists of several kinds of textile fabrics, iron goods, and corn; those from Brazil, of hides and colonial produce; the Americans bring timber and whale oil, and the Portuguese liquors, textile fabrics, colonial produce, silver coin, soap, and hats.

This island was discovered in 1444 by Calvet, and was settled in the following year. Since that period it has remained in possession of the Portuguese. (Boid's Description of the Azores, or Western Islands; Hout's Description of the Island of St. Michael, in London Geog. Journal, vol. xvi.)

MICHIGAN, since the article in P. C. was written, has become a State. A sketch of the new constitution and other particulars given under United States of North America, P. C. S.

MICHIPS. [Jovinella, P. C.; Humida, P. C.]

MICON (Mioor or Mioor), a distinguished Greek painter and sculptor, the son of Phanocles of Athens, and one of the most celebrated of the Greek painters for painting horses. He lived about the middle of the fifth century before Christ, and was the contemporary of Phidias and Polygnotus.
The picture of Micon is less known than that of the others of the eminent artists of ancient Greece. He was however one of the painters chosen by the Athenians to perpetuate their great victories in the Colonades of the Ceramites, which was enlarged or rebuilt by Cimon after his victories over the Persians; and he was also appointed to paint the walls of the temple of Theseus at Athens; an honourable distinction, indicating the highest eminence in his art.

Micon painted the battle of the Amazons and Athenians under Theseus, in the gallery of the Ceramikes, which was called subsequently, in consequence of this and other pictures, the variegated gallery, or the Pocell (pauçetv), or the Painted Gallery (Xronos). A much greater proportion of the picture of the battle of Marathon, in the same gallery, for it is said that he was fined 30 mina, or half a talent, for painting the Barbarians larger than the Greeks, in that picture.

In the battle of the Greeks and Persians, Micon painted the Amazons and Athenians; and opposite to it the battle of the Centaurs and the Lapithae. A third wall also was painted by Micon in this temple, but the picture was so much defaced by time that it has now been entirely effaced, though the fragments remaining do credit to it. Micon also painted, together with Polygnotus, the temple of the Dioscuri; he painted there the return of the Argonauts to Tessalessy with Media and Aetopeneus and Antiope, the daughters of Peleus; they were so called according to this
The following verses are under Mierevelt's portrait in the first edition of Van Mander, which was published during his lifetime:

Plaguedo a. vivum, quo non praestantes alter;
Depresses peritis tauri Mediae Cithara
Principis magalis facit lavatas
et suis praestior

(Van Mander, Het Liv van de Schilders, etc., ed. 1764;
Houbroek, Groote Schouwburg der Nederlandsche Kunstschillers, etc.)

MIGLIARA, GIOVANNI, a very distinguished modern Italian artist, who invested architectural painting with a species of interest which it had not before possessed even in the eldest masters. He was born at Alessandria in Piedmont, October 15th, 1785, of poor parents, who planned to send him to a carriage-maker, Zuccoli of Milan, to learn wood-carving; but on discovering his strong and peculiar talent, Zuccoli sent him to study architecture and perspective, under Alborelli and Levati, at the academy of the Brera. So prepared, he next studied scene-painting under Galiari, and practised that branch of art—for which Milan was then celebrated beyond any other place in Europe—about eight years, 1792-10, sharing the fame reaped by Galiari, Perego, Landrani, and Sanmicheli. This eminently successful career, one moreover which he pursued with such devotedness, was all at once arrested by a long and dangerous illness, occasioned by a violent exertion of body, partly by a pulmonary attack in consequence of cold caught while working in a damp place. This perhaps eventually proved a great advantage both to himself and to art, insomuch as it compelled him to take a long time to recover, and led him to produce works that are now treasured up for admiration in galleries. At the time however his illness was a serious calamity, for his family were reduced to very great distress. Owing to his death the family fortunes were forgotten, he was no longer obtruded upon, and no sooner did he begin to do so, and was able to sit up in bed, than he employed himself in making pictures on a small scale of the various scenes—amounting to about a hundred—whichever he had painted for the theatres. Produced through necessity, as the only means of earning subsistence for himself and family, these subjects not only found purchasers, but there became even a demand for them. Thus encouraged he determined to try his hand at monumental scenery in small, and also to combine the dramatic with the scene-painter, peopling his canvass not with mere figures as accessories, but with episodical groups of actors, either illustrating popular and local manners, or recording some historic incident; and among his numerous pieces of the latter class may be mentioned his Ileigondus, Adelhade dying in a souterrain of the Trappists, the Consecration of a Temple, the Ducale di la Valliere, and Charles V at a Council. In depicting the personages and manners of material and everyday life, he displayed a vein of strong humour; and his conventionality of persons and refectories, and incidents taken from Porto- dialet poems, remained, in an era of classicism, foreign to the public. Indepently of the figures and stories—the great attraction for the many with which he baited his productions—he converted archetypal pictures into perfect portraits of buildings into real picture, by the united mastery of perspective, chiaroscuri, and colouring. His pictures give the impression and sentiment of the edifices themselves, and are stamped by illustré yet anything but promiscuous reality. Such was the reputation he acquired, that not only the King of Sardinia bestowed upon him the Order of Merit, but his native city Alessandria struck a medal in honour of him. In 1789, Honoured and prosperous in his profession while only in the meridian of life, he might, not unreasonably, look forward for years of uninterrupted happiness, when he was carried off very suddenly—in about half an hour after being seized by a violent haemorrhage. His remains were interred in the church of San Marco, was born in 1729, and practised as an artist, in subjects of the same kind as her father. (Giuseppe Sacchi, in Tipaldino's Biografia; Westminster Rev., vol. 15.)

MIAK'NIA, a genus of plants belonging to the natural order Composita, to the suborder Tubiflorae, to the tribe Eupatoriacese, and the subtribe Adenostylceae. It has a shaggy, hoary, hairy, somewhat rough, scabrous, lanceolate, with a little curl at the end and a little bristle; the tube of the corolla short, with the throat dilated and somewhat campanulate; the anthers somewhat protruded; the achenium angular; the pappus in 1 row, rough and hairy.

2Q2
M. officinalis has an erect, smooth, nearly simple stem, with leaves decussating somewhat triangular-ovate, coriaceous with a great sinus, toothed at the sides, entire towards the point, through the epidermis coriaceous and papery. This plant is a native of Brazil, where it is called Corapão de Jeu. It is a handsome plant. The leaves contain a bitter principle and an aromatic spirit, and are used as a medicine and the plants are likewise used in the Cascara and Chinona barks. They are said to be an especially valuable remedy in remitting fevers and in atonic dyspepsia. They are administered in the form of decoction.

M. Guaco, Guaco plant has an herbaceous twining stem; the branches round, sulcate, hairy; the leaves stalked, ovate, somewhat acuminate, shortly narrowed at the base, remotely toothed on the margin above, hairy beneath; the flowers axillary, stalked, opposite; the heads somewhat ternate sessile; the bractlets linear, shorter than the involucres; the involucral scales linear-oblong, obtuse, downy; the anthers smooth. This is one of the plants called Guaco in South America, and is also called the 'pupil.'

M. ulcers, Matico is a remarkable plant; the juice was used in a way that shows its value. The whole plant was excited immediately after it is received is undoubtedly the safest plan. Besides the guaco there are several other plants used in South America, some of which are called guaco, as the Herpetes colombiaca, Dorstenia tubicina, Aristolochia cyanophylla, etc. The guaco has been tried in this country as a remedy in hydrophobia, but without success. The Uruli, or snake-poison of the Indians of British Guiana, is its compound, and contains the same principle. This is C. C. M. opifera is a smooth climbing plant, with an angular stem; it has stalked, cordate, acuminate, repand-toothed or nearly entire leaves, when full grown rather blunt; the heads are sessile, with a calyx of C. C. It is also employed against the bites of snakes, and is said to effect a cure by its powerful diuretic action. An account is given of this plant by Gomez in the Memoirs of the Royal Academy of Lisbon for 1813, where it is described as the Epatorium carnatum. The genus Mikania is closely allied to Epatorium, and they belong to a group of plants in the order Compositae, the most remarkable for their activity. Dr. Lindley states, in his 'Vegetable Kingdom,' that the genus is said to produce of Epatorium glutinosum, and not of Arantia elongata, as has been usually supposed. Of this plant Mr. Hartwig says, in a communication to Dr. Lindley, 'Matico is the name applied to the tuber of Eupatorium glutinosum, or the Chusmolena in the Quichua language. It forms a shrub 3-5 feet high, and is common in the higher parts of the Quichuan Andes, where its properties were discovered. It is a tree called Matico (Rutie Mathew), who when wounded in action applied accidentally the leaves of some shrub to his wound, which had the immediate effect of stopping the bleeding and healing the wound. This shrub turned out to be the Chusmolena, which has since been called, in honour of its discoverer, Matico. It is the true Matico of the inhabitants of Quito and Riobamba I have not the slightest doubt; both leaves and specimens have been gathered by myself and my compatriots in this species, and I have no doubt that my examination of the plant found them to agree exactly with his Eupatorium glutinosum.' The Matico has been used in Europe, and is said to be an unusually efficacious and of great value in stopping the bleeding from small wounds. (Poeppig, 'Reise in Chilen, Peru, etc.,' Lindley, 'Vegetable Kingdom; Lindley, 'Flora Medicina.')
were among the Romans. Besides the infliction of a certain number of lashes with cords, soldiers convicted of theft, marauding, or any other breach of discipline which was not punishable with death, were sentenced to run the gauntlet as it was called. For the execution of this sentence the regi-
ments was arrayed as in battle, divided into two lines, furnished with a small stick, generally of oak (except the grenadiers, who used their belts instead of the sticks), the culprit, naked to the waist, was either marched slowly or al-
lone at the head of one line, or he could, on the other, from the head to the rear extremity between the two lines, each man striking him as he passed along. In certain cases the offender was afterwards expelled from the regiment, and sometimes also arrested, with a view never to appear there again under pain of death. The punishment of the knout, in the Russian army, consists in the naked back of the offender being struck with a leather belt.

Cavalry soldiers were frequently punished by the picket, as it
was called; this consisted in the man being made to hang
by his hands from a beam during a certain time, a stake with
its upper end made sharp being planted in the ground under
him; so that, when from weariness he could no longer keep
himself up, his foot was pierced by the stake: this kind of
punishment has been long since abolished.

Criminals formerly that soldiers, being goaded to
madness by the pressures exercised on them, either from
caprice or from a mistaken opinion that strictness in the
least details of discipline is as necessary as in points of
their importance, have murdered the officers, when
they considered themselves wronged, and have afterwards, apparently
without regret, suffered death for the crime.

Confinement in a dark room during a certain number of hours
is, a frequent punishment of distinguished offenders, without leave from parents, either on account of drunkenness
or from any other cause; and soldiers so offending were
formerly made to stand or rather to revolve in a cage or pillory
which continually turned on its axis.

Besides the punishments of death and transportation, which,
for great crimes, are within the scope of military law, in the
British army, breaches of discipline are visited by flagellation, terms of imprisonment, extra duties, extra fatigue,
the performance of fatigue duties; but the punishments which
consist in confinement to barracks and laborious employments,
continued during long periods at the discretion of commanders
of regiments, have been abolished by an express order from the
present commander-in-chief.

While an army is in the field it is evident that breaches of
discipline should be punished with extraordinary severity, and
that the punishment should follow almost immediately on de-
tection. It might be presumed that acts of treachery will
seldom be committed; but unfortunately desertions to the
enemy frequently take place; the more usual crime is how-
ever of quelling the disorders into which the country, a circumstance which is generally accompanied
by gross acts of violence, often murders, committed on the
defenceless people; and no doubt can exist that soldiers guilty of
such deeds, must, in ordinary times, be treated as traitors. Even
guilty of a minor offence, when the crime is less heinous, the well-being and perhaps
the safety of the army may be perilled in consequence of the
spirit of resentment induced in the inhabitants of the country
by injuries inflicted on them: such disorders should therefore
be repressed by making signal examples of the offenders.

It may be said also that the vice of drunkenness in soldiers
deserves, in general, the heaviest punishment: the miscarriage
of an enterprise, and death from the loss of numbers of
gallant men in an action, may be the fatal consequences of a
failure, from inebriety, in the delivery of a report or order.

That the trial and, on conviction, the punishment of an
offender do not properly belong to this instance is also evident:
the army may change its position or cantonments, when,
if any delay takes place, it may be impossible for the necessary
witnesses to arrive, or these may in the mean time be re-
moved by a change of quarter. A serious fault in a uniform line
between the commission of a crime and its punishment diminishes the fear
of the latter by opening to the culprit another chance of escape; it moreover diminishes the effect of the punishment as a correction for evil future behaviour, and accordingly
was, off, and the punishment assumes, in some measure, the ap-
pearance of an act of cruelty.

The circumstances of an army in a time of peace and in a
time of war, or even the men in the presence of an enemy, are
very different: in the former case soldiers have no oppor-
tunity to commit treason or to pillage a country; and since
the generality of the men who then enter the army are such
as have a fair moral character, great crimes among them are
as unfrequent as they are among an equal number of men in
any other condition of life: the punishments for such offences
as may be committed are, in double time, greater; the same
prophecy is of the same nature and degree as much which was
drawn from the commission of a crime and its punishment
concerning the peculiarity of the crimes; for it may be
judged for corresponding offences by the ordinary courts of
justice. Imprisonment for a time, employment in laborious
tasks, but particularly a forfeiture of personal privileges, where
the offender is without a family depending on his for
wages, might, probably with advantage, be made the punishment for
military offences.

The usual sentence now for breaches of discipline is that
a certain number of lashes be inflicted on cords on the naked
back of the offender: this kind of punishment is both cruel
and disgusting; and, which is worse, it leaves on the skin
during life the emblem of disgrace which, if discovered by any
accident, cannot fail to produce a prejudice against the in-
dividual, how well soever he may have conducted himself sub-
sequently to the infliction. It falls, moreover, with unequal
effect on different persons according to their state of their
health, or of their nervous systems at the time; and not un-
frequently, according to the will of the person who adminis-
ters or who superintends the punishment. It may be said
that many of these officers who are drenched in their
minutest caprice, without a moment's regret, are, at the
same moment, neither avoid sympathizing with the culprit nor becoming
dissatisfied with a service in which they are exposed to such
disgrace and suffering.

The disadvantages under which, during his whole life, an
individual may labour who has once suffered the punishment
of being flogged, are strikingly related in General Sir Charles
Napier's Remarks on Military Law,' p. 158, &c. This dis-
advantage is of different kinds, each of which is visited
only in a degree suited to the crime, and when circum-
stances prevent a different kind of punishment from being
used, may occasionally be effectual; but he gives cogent rea-
sons for considering it to be both wise and humane that the
number of lashes which a court-martial was formerly allowed
25, to prescribe is now diminished, and for abolishing the punish-
ment entirely in times of peace.

Sir Charles Napier has said; that, and forty years before the time
at which he wrote (1837), he frequently saw from 600 to
1000 lashes inflicted in consequence of sentences of merely
regimental courts-martial; and in those days a man who had
suffered a part of the punishment was often brought from
an hospital when the wounds were barely healed, to receive the
remainder. At present even a general court-martial cannot
sentence a man to receive more than 200 lashes. The of-
ference of inducing a soldier to desert, in which case was
visited with 1000 lashes, is, according to the present military
law, punishable only by 'fine or imprisonment, or both, as
the court shall adjudge.'

With respect to the effects of the law in its actual state, it
may be observed that the discipline of the British army,
during the time that it served in Spain and France, is ac-
nowledged to have been more perfect than it had been in
any former times. But it may be said, however, that the use of the lash be
only gradually abolished; the milder punishments being substituted as often as possible.

The practice of giving rewards for good behaviour, now so
happily introduced in the military service, and the instruction
obtained at the regimental schools, will in time, it is hoped,
operate a beneficial change in the characters of such men as
have not, from nature or from early education, a just sense
of moral rectitude and of the obligations all are under of pun-
tually and faithfully discharging the duties they owe to their
country. It is indeed probable that such means will entirely
supersede the necessity of a punishment which degrades a
brave soldier by placing him below the level of a brute.

MILITARY TENURES. [FEUDAL SYSTEM, P. C.]

MILLIUM, a genus of grasses belonging to the tribe
Agrostidiace. It has membranous glumes, nearly equal,
armed; the lemma 2, nearly equal, unarticulated, as the
glumes, and hardening on the fruit; the spikelet convex on
the back, or slightly dorsally compressed. There is but
one British species of this genus, the bent grass, an
acuminated, linear-lanceolate leaves. It has a stem 3 or 4 feet in height, and is
found in damp shady woods.

(Balington, 350; see British Botany.)

MILL, MILLWORK. [Wheel, P. C., p. 810; Wind-
mill, P. C., p. 445; Windlass, P. C., p. 450; Coupling
P. C., p. 483; Gear, P. C., S., p. 648.]
MILLINGEN, JAMES, a very eminent English archaeologist, was born in London, on the 18th of January, 1774. His father, who was a Dutch merchant, placed him at an early age at Westminster School; the boy showed a great partiality to every species of the ancient collections, and the frequent opportunities of seeing a good collection in the house of one of his father's friends. His principal study in his leisure hours was the science of war, and he was anxious to enter the army in which he might have the opportunity of suffering as an artist, his father determined to send him from Westminster to one of the universities. However, the French revolution, which broke out at the time, changed his plans, for Millingen's father had more than one friend in the army, and it seemed best to delay the boy's departure for a time. To avoid the dangers of the times, he made a journey to Paris, where he associated with the most celebrated writers on antiquities, and from his conversation there, he became acquainted with the most celebrated writers of France. He spent some time at Paris, and was then sent to the University of Paris, where he continued his studies for some time. In 1822, he was received as a member of the American Philosophical Society, and in 1837, he was elected a member of the Royal Society of London. (Classical Museum, part x, p. 91, &c.)

MINERALOGY. It will be seen by the number of substances now added under this head, that mineralogy has made considerable progress of late years. To the new substances which have been discovered, and which are now described, are added some which had before accidentally escaped notice. In various treaties on mineralogy there will be found descriptions of some bodies which we have omitted to notice, and in those cases it is to be considered that the substances did not appear to possess the novelty ascribed to them, or had been previously described under other names. We mention this as a general rule, though we are not without apprehension that minerals may by mistake have been omitted which ought to have been inserted.

ARSENITE. (Filippetti, P. C.)

ARSENITE. (Bichat, A. M. C.)

ARSENITE. (Titanium, F. C.)

AGATEM. (Zeolite, P. C.)

ALUMINA. (C. L. D.)

ALUMINA. (Websterite, Subm. Alumina) occurs in reinforn masses and botryoidal concretions. Colour white or yellowish white. Stearum white. Fracture earthy, Soft, transparent. Translucent. Specific gravity 1.06. Found at Sarajevo in Bosnia, and near Calabia in Calabria. Analysis:—Sulphuric acid, 36.4; alumina, 16; water, 40.6; peroxide of iron, 0.4. Dr. Thomson's analysis gives 28.6.

ALUMITE. (Websterite, Subm. Alumina) occurs in reinforn masses and botryoidal concretions. Colour white or yellowish white. Stearum white. Fracture earthy, Soft, transparent. Translucent. Specific gravity 1.06. Found at Sarajevo in Bosnia, and near Calabia in Calabria. Analysis:—Sulphuric acid, 36.4; alumina, 16; water, 40.6; peroxide of iron, 0.4. Dr. Thomson's analysis gives 28.6.

AMPHIBOL. (Augite, P. C.)

AMPHIBOL. (Lecite, P. C.)

AMPHIBOL. (Travertine, P. C.)

ANDALUSITE (Amphibolite Sulphate of Lime) occurs massive and crystallized. Primary form a right rhombic prism. Cleavage very distinct parallel to the terminal planes and their two diagonals; parallel to the lateral planes indistinct.
Fracture uneven. Colour white, bluish, violet or reddish. Lustre vitreous, peary on the cleavage surfaces. Hardness 3 to 3½. Transparent, translucent. Refraction double. Specific gravity 2½ to 2½. Massive varieties among, andalusite, nodular, reniform. Found at Haile in the Tyrol, Ben in Switzerland, and in the salt-mines of Upper Austria and Salzburg, &c. Analysis of a specimen from Sulz:- Sulphuric acid, 57; lime, 42; silica, 2.

ANALKERITE occurs crystallised. Primary form a rhomboid. Cleavage parallel to the prismatic plane. Colour yellow, sometimes yellowish or brownish from an admixture of oxide of iron. Fracture uneven. Hardness 3½ to 4. Lustre vitreous, translucent. Specific gravity 2½. Found at Salzburg and in the Alps, &c. Analysis, by Berchier:- Carbonate of lime, 51½; carbonate of magnesia, 25½; carbonate of iron, 20½; carbonate of manganese, 30%.

ANTIMONITE. [Zoelites, P. C.]

ARAWEIDONITE occurs amorphous. Cleavage parallel to the lateral planes and both the diagonals of a rhomboid prism. Colour olivaceous. Hardness 0½. Lustre vitreous. Opalescent opaline. Specific gravity 3½ to 3. Found in Norway and Greenland. Analysis, by Dr. Thomson: Silica, 50½; protode of iron, 35½; sesqui-oxide of magnesia, 8½; soda, 1½; lime, 5½; water, 13; Specific gravity 0½; found in the Bed of the Morice, near Kiel in Holstein, Kongsberg, and in the salt-mines of Upper Austria and Salzburg, &c. Analysis of a specimen from Sulz:- Sulphuric acid, 57; lime, 42; silica, 2.

ATAZAMITE (Chlorochlzoide of Copper, Muriate of Copper) occurs massive, pulverulent, and crystallized. Primary form a right rhombic prism. Colour green of various shades, but chiefly emerald green. Lustre strong. Fracture uneven. Hardness 3½ to 6. Lustre vitreous. Translucent to opaque. Specific gravity 4½. Found at Remolassa in Chile, and the pulverulent variety at Atacama in Peru. Massive variety零售, with a fibrous structure. Analysis, by Proest: Muriatic acid, 10½; oxide of copper, 76½; water, 12½.

AUTOMALITE. [GARRETT, P. C.]

BARCHEUITE occurs amorphous, and granular distinct concretions. Colour yellow-green. Lustre vitreous. Translucent. Specific gravity 3½. Found at Arendal in Norway, the Shetland Islands, and United States at Charlestown, Mass. Analysis, by Arpke, of a specimen from Arendal: Silica, 54½; carbonate of iron, 21½; lime, 19½; magnesia, 2½; protode of manganese, 1½; alumina, 0½; volatile matter, 0½.

BALTIMOITE is composed of longitudinal fibres adhering to each other. Lustre silky. opaque, but in thin pieces translucent on the edges. Hardness less than that of calcareous spar. Found at Baltimore, U.S. Analysis, by Dr. Thomson: Silica, 40½; magnesia, 34½; protode of iron, 10½; alumina, 1½; water, 12½.

BARTONSTROMHITE. [STROMMEN, P. C.]

BAROCHNITE occurs in amorphous, or amorphous confusedly lamellar, or composed of distinct elongated prisms. Cleavage parallel to the axis of the prism. Colour dark steel grey, inclining to brown. Lustre metallic. Found at Chelles in
M I N

304

M I N

An. Analysis, by Kohler: Silica, 57.19; magnesia, 82.57; lime, 1.29; protodote of iron, 7.46.

Brookite. [TITANIUM, P.C.]

Brochite. [MACABREIT, P.C.]

Boskervreuz. [COFFER, Purple, P.C.]

Boskervreuzite occurs in irregularly disposed prismatic crystals, having a characteristic structure, brown, grey, green, or reddish colour. Nearly opaque. Hardness 6-6 to 7-0. Lustre somewhat silky. Specific gravity 3.1 to 3.23. Found at Real de Minas in Mexico. Analysis, by Dumas: silica, 49.90; protodote of magnesium, 36.06; lime, 14.57; protodote of iron, 0.81.

Cacholong. [OPAL, P.C.]

Cadmium. Sulphate of. [GERSOYKITE]

Cadm睚onite occurs crystallized. Primary form a rhombic prism. Cleavage parallel to the primary faces, and to the short diagonal of the prism. Colour blue and greenish blue; streak bluish or greenish white. Fracture uneven. Hardness 2-5 to 3-0. Lustre resinous to resinous. Translucent, transparent. Specific gravity 6.2. Found at Lead Hills in Scotland. Analysis, by Brooke: Carbonate of lead, 32.8; carbonate of copper, 11.4; sulphate of lead, 56.8.

Carnegie. [RHYOLITE, P.C.]

Carnihite. [LEAD, P.C.]

Chabazit. [ZEOCLITE, P.C.]

Chalcolite. [URANIUM, P.C.]

Chabazitite. [P.C.]

Chalcedony occurs crystallized. Primary form a rhombic prism. Cleavage in planes parallel to the axis. Colour yellow, brownish yellow; streak white. Fracture uneven. Hardness 2-5 to 3-0. Lustre resinous or inclining to resinous. Transparent, translucent. Found near Tavistock, Devonshire, and at Crinnis, Cornwall. Analysis: Wollaston has shown it to be composed of phosphoric acid, alumina, and iron. The hardness has not been determined.

Chlorite. [TALC, P.C.]

Chloropoc occurs massive, amorphous. Fracture concrete, compact and splintery. Colour green, sometimes reddish brown. Structure compact, sometimes earthy. Hardness 3-0 to 4-0. Lustre of the compact, dull resinous. Opake. Specific gravity 1.7 to 2.0. Found near Ungurh in Hungary. Analysis, by Brandes: silica, 46.0; oxide of iron, 38.3; magnesia, 2.0; alumina, 1.9; magnesia, a trace; water, 18.0.

Chlorophyllite. (Hydrous Jolite) occurs crystallized in six-sided prisms, the edges of which are usually replaced by so many planes that the crystals appear almost cylindrical. Colour grey; fracture compact. Hardness 2-5. Colour green, greenish brown or dark olive-brown. Translucent. Specific gravity 2.705. Found in the Alps, Aosta, and also at Unity, N. H., in the United States. Analysis, by Bondorf, of the mineral from Abo: Silica, 45.05; alumina, 30.05; magnesia, 9.00; protodote of iron, 5.30; water, 10.00.

Chlorinitite occurs rounded in masses. Is not cleavable. Fracture uneven and imperfectly conchoidal. Colour white, with shades of yellow and grey. Hardness between 2-0 and 4-0. Lustre glimmering or dull. Transparent, often only on the edges. Found at Elba. Analysis, by Von Kobell: Silica, 36.99; alumina, 17.12; magnesia, 32.90; lime, 12.00; protodote of iron, 1.46; water, 9.00.

Chlorocolla occurs massive. Sometimes in pseudo-massive beds, botryoidal and reniform. No cleavage observable. Colour bluish and blackish-green; streak green. Fracture earthy or conchoidal. Hardness 2-0 to 8-0. Lustre vitreous-opalescent. Translucent. Opake. Specific gravity 2.031. Found at La Granja del Prado, in Hungary. Art. Analysis, by Kobell: Silica, 36.44; oxide of copper, 40.00; water, 26.20; iron, 1.00. It is more than probable, as shown by analysis, that calcite and quartz, merely coloured by copper, have been converted into chlorocolla.

Cinnabarrine. [GANET, P.C.]

Cleavage. [LILACITE, Albitte]

Cleavage occurs massive and crystallized. Primary form a doubly oblique prism. Cleavage parallel to the plane of the colour, sometimes yellowish or reddish green, bluish, or red; streak white. Fracture uneven. Hardness 6-0. Lustre pearly on the cleavage planes, vitreous in other directions. Transparent, translucent. Specific gravity 2.6 to 3.88. The massive varieties have a lustrous structure. Found in Norway, Sweden, Dauphiny, St. Gothard, and Scotland, and accompanying felspar in most of its numerous localities; from this it differs chiefly in containing soda instead of potash; obtained near St. Gothard. In the Rhine. It does not appear to have been analysed.

Clintonianes (Seybertite, Xanochiphylite Holme) occurs crystallized, and in imperfectly crystallized masses. Primary form a rhombic prism. Colour greenish, red, or reddish brown, yellowish brown, and red; streak yellowish grey. Hardness 4-5. Lustre metallic and metallic pearly. Translucent to opake. In thin laminae sometimes a slight prismatic gravity 3.08. Found at Amity, Orange Co., N. Y. Analysis, by Clemson: Silica, 17.0; alumina, 37.6; magnesia, 24.3; lime, 10.7; protodote of iron, 4.0; water, 3.6.

Copper. [PHOSPHENE, P.C.]

Compositite. [ZEOCLITE, P.C.]

Condorite. [Macabrite, P.C.]

Conquimite. (Sulphated Periclase of Iron) occurs in granular masses, some parts of which are crystallized. The crystals are regular hexagonal prisms, terminated by six-sided pyramidal ends. Embryonic soda in water. Colour white, and also of various shades of brown, yellow, red, and sometimes even of a deep blue colour. Found in the southern part of Peru near Calama in Bolivia, and near Copiapo in Chili. Analysis, by Rose: Si, 51.52; lime, 43.54; water, 24.91; alumina, 0.78; lime, 0.14; magnesia, 0.21; silica, 0.37; water, 9.28.

Cristobalite. [TITANIUM, P.C.]

Cronstedtite. (Hydrous Silicate of Iron) occurs massive and crystallized. Primary form a rhomboid; in small, thin, hexagonal prisms, and in radiating laminae parallel to the axis distinct. Colour black and brownish black; streak dull green. Hardness 2-0 to 2-5. Lustre vitreous.Opaque. Specific gravity 3-3 to 3-8. Found in Cornwall, Brazil, and Prussia in Bohemia. Analysis, by Steinmann: Silica, 22.45; oxide of iron, 58.85; oxide of manganese, 2.89; magnesia, 5.08; water, 10.70.

Cure Ores. [PHARMAKOGRITHE.]

Cummingtonite. [AGOPITE, P.C.]

Cynophane. [Chemodite, P.C.]

Danaites (Arsenical Sulphate of Iron and Cobalt) occurs crystallized. Primary form a right rhombic prism. Colour brown with a tinge of steel grey; streak dark greyish black. Fracture uneven. Brittle. Hardness 6-5 to 6-0. Lustre metallic. Specific gravity 6-127. Found at Franconia, N. H., at Jackson, N. H., and other places in the United States. Analysis, by Faraday: Sulphur, 17.56; arsenic, 41.44; iron, 32.94; cobalt, 0.45.

Danburite occurs crystallized. Primary form an oblique rhombic prism. Colour honey-yellow, becoming nearly white by decomposition. Fracture steely grey; streak dark greyish black. Hardness 6-6 to 6-0. Lustre vitreous. Translucent, transparent. Specific gravity 2-88. Found at Danbury, Ct. Analysis, by Shepard: Silica, 5.6; lime, 28.35; alumina, 1.70; yttria, 0.85; potass, soda, and loss, 51.90; water, 4.09.

Davyite occurs crystallized. Primary form a rhomboid. Cleavage parallel to the planes of the hexagonal prism. Colour white, sometimes yellowish brown; streak white.
Fracture conchoideal. Hardness 6 to 6.5. Lustre vitreous. Transparent, translucent, opake. Specific gravity 2.4. Found in Pegmatite rocks of New Brunswick. Analysis, by Covell: Silica, 42.97; Alumina, 23.29; magnesia, 12.95; peroxide of iron, 1.25; water, 7.43; loss, 3.11.

Dermatococc occurs in reniform masses, rarely globular, and also in thick lamellar, encrusting, or brown or liver brown. Streak yellow inclining to grey. Fracture conchoideal.Feels greasy, but does not adhere to the tongue. Hardness about 2. Lustre somewhat renisous. Specific gravity 2.15. Found in the Agapite quarry near Wathem in Saxony. Analysis, by Felius: Silica, 35.60; magnesia, 23.70; peroxide of iron, 11.33; proteide of manganese, 2.25; alumina, 0.416; lime, 0.833; water and calcined matter, 32.29.

Dialase. [Adote, P. C.]

Dissaper occurs massive and crystallized. Primary form a doubly oblique prism. Colour slightly greenish grey and yellowish brown. Hardness 6 to 6.5. Slightly translucent. Specific gravity 3.43. Found at Kossobud in the Orenburg government of Asiatic Russia. Massive variety occurs in slightly curvilinear lamina of a shining pearly lustre and greenish-grey colour; also in cellular masses, constituted of slender crystals, which have a pearly lustre and intercept each other in every direction; of a brown hue externally, but perfectly transparent and colourless when reduced to thin leaves. Colour brown. Hardness 5.1 to 6.3; 14.46. The brown variety, analyzed by Children, gave—alumina, 76.06; water, 14.70; oxide of iron, 7.78; loss, 1.46.

Dyselite occurs in small radiated masses. Colour olive or dull green. Slightly translucent and extremely fusible. Specific gravity 3.27. Found at Anglar, near Limoges. Analysis, by Dr. Thompson: Sulphate of iron, 25.4; of manganese, 51.69; of lime, 16.80; of oxide of iron, 41.93; of proteide of manganese, 7.60; of Silica, 2.956; moisture, 0.60. Dyselite occurs crystallized in regular octohedrons. Cleavage rather imperfect, parallel with the faces of the crystal. Colour white or greyish brown. Hardness 4.5. Fracture conchoideal. Hardness 6.5. Somewhat translucent, opake. Lustre vitreous, inclining to resinous. Specific gravity 4.651. Found at Sterling, New Jersey. Analysis, by Dr. Thomson: Alumina, 50.40; oxide of iron, 16.80; of oxide of iron, 41.934; of proteide of manganese, 7.60; of Silica, 2.956; moisture, 0.60.

Eliolait. Occurs fibrous or feathery and massive. Colour white or greyish brown. Hardness 4.5 to 5. Found at Alladell in Smalld, Cizlulow in the Banate, and in Norway. Analysis, Silica, 61.85; lime, 39.15; with small quantities of magnesia, alumina, and iron. Another compound under this name has also been called the Alladell red zelote. It agrees in composition with stilbite, except that it contains two cent. less of water.

Eschobro [Sulfite] does not occur crystallized, but in compact or finely fibrous masses, and occasionally in thin lamina. Colour green, grey, or brownish. Lustre vitreous or resinous. Transparent. Analysis, by Ekeberg: Silica, 46.59; lime, 39.8; soda, 5.8; oxide of iron, 0.75; water, 2.25.

Echolatte (Fattelein) occurs in amorphous masses, with cleavages parallel to the lateral planes, and both diagonals of a rhombic prism. Structure conchoideal.Colour dark green, bluish grey, or greyish or brownish red. Hardness 5 to 6. Lustre resinous, frequently opalescent when cut. Transparent. Specific gravity 2.54 to 2.93. It is found at Lord, Stain, and Brecknock in the Yorkshire. Analysis, by Vauquelin: Silica, 44.00; alumina, 34.00; soda, 16.50; peroxide of iron, 4.00; lime, 0.12. Gmelin found also 4.73% of peroxide of iron, 0.08.

Electrite. [Gold, Allote, P. C.]

Epromite (Sulphate of Magnesia) occurs massive, botryoidal, and reniform, on the surface of other bodies, and in solution in sea and mineral waters. Colour white. Streak white. Structure fibrous, sometimes earthy. Brittle. Taste bitter and saline. Found originally in a spring at Epeom. It forms a large bed near Arequipa in Peru, and is often in fine crystals and silky fibres.

Erinite (Arsenate of Copper) occurs in concentric and mammillated layers, between which other arseniates are found. The layers have rough surfaces and a fibrous structure. Colour brown, grey. Hardness 5 to 6. Streak pale. Fracture uneven or imperfect conchoideal. Hardness 4.5 to 5. Lustre slightly resinous. Slightly translucent. Specific gravity 4.0 to 4.1. Found near Limerock. Analysis, by Turner: Arsenic acid, 59.87; oxide of copper, 50.44; alumina, 1.77; water, 5.01.

Erinite. [Zeolites, P. C.]

Esklitui occurs massive and amorphous. Fracture in some specimens foliated, in others splintery. Structure granular, compact. Colour light greenish grey. Hardness 7 to 7.5. Lustre vitreous, shining. Hardness 6.25 to 7.0. Lustre feebly shining, or dull. Opake. Specific gravity 3.5 to 3.1. Found near Erd in the Saxon, England, growing on a bed of 100 fathoms in thickness. Analysis, by Gneisii: Silica, 53.16; alumina, 14.03; lime, 14.39; magnesia, 5.2; soda, 2.61; oxide of iron, 7.14; oxide of manganese, 0.64; water, 0.60.

Eusechroite (Arunate of Copper) occurs crystallized. Primary form a right rhombic prism. Cleavage indistinct, Colour bright emerald green. Streak pale apple green. Fracture uneven. Hardness 3.5 to 4.0. Lustre vitreous. Refraction double. Transparent, translucent. Specific gravity 3.38 to 3.41. Found at Libethen in Hungary. Analysis, by Turner: Arsenic acid, 53.26; oxide of copper, 47.05; water, 18.90.

Esstrukte occurs massive without any trace of cleavage. Colour brownish black. In thin splinters has a reddish brown transluence, lighter than the streak. Streak reddish brown. Fracture subconchoidal. Hardness, scratches thiorie. Lustre metallic, greyish brown. Hardness 4 to 4.3. Found in Norway. Analysis, by Scherer: Columbic acid, with some tin acid, 46.96; tin acid, 7.94; yttria, 25.06; proteide of uranium, 0.84; proteide of cerium, 2.18; oxide of lanthanum, 0.96; lime, 2.47; magnesia, 0.25; water, 3.97=9.30.

Faimake. [Pyrroxyne, P. C.]

Faizalite occurs crystallized in the form of an octahedron with a square base. Colour white, sometimes brown. Fracture vitreous or uneven. Fragile. Lustre brilliant. Found at Kalashatur in Bresigum. Analysis, by Daurou: Silica, 49.36; alumina, 18.77; lime, 5.00; soda, 4.34; water, 22.49.

Fibrolite. [Kyanite, P. C.]

Gadolinite. [Ythrium, P. C.]

Gedrite occurs in crystalline masses, having a fibrous, radiated, or lamellar structure. Colour close brown. Streak grey or yellowish. Lustre submetallic, feeble. Hardness not above 5.0. Rough. Specific gravity 3.26. Occurs in loose stones near Gedre in the Pyrenees. It has some resemblance to a hyaline. Analysis, by Goni: Silica, 38.811; alumina, 9.309; proteide of iron, 46.35; magnesia, 4.130; lime, 0.686; water, 2.301.

Gekrozerite (Kilbridecaseite) occurs amorphous without cleavage. Fracture lamellar in one direction, and in the other...

Gloablite occurs crystallized in six- and twelve-sided prisms. Cleavage parallel to the six sides of the prism. Colour greenish to dark steel grey. Lustre between vitreous and waxy. Hardness about 3-5. Specific gravity 2-662 to 2-673. Found near Temnella in Finland. Analysis, by Wachtmeister: Silica, 46-27; alumina, 25-10; peroxide of iron, 15-60; magnesium, 3-80; proteoxide of manganese, 0-90; potash, 2-70; soda, 3-20; water, 4-5; ammonia, 0-80.

Gmelinite. [Zeolites, P. C.]

Gondalite. [Lead, Ores of P. C.]

Green Iron Earth (Hydrochlorite) occurs in reiform, botryoidal, and globular masses. Colour green, passing into black and yellow. Lustre resinous and dull. Brittle. Found at Selmouth in Saxony. Analysis by Muller: Silica, 56-17; oxide of bismuth, 15-05; alumina, 14-65; oxide of iron, 10-54; phosphoric acid with traces of manganous, 5-62.

Greenstone occurs in small amorphous crystalline masses. Primary form a doubly oblique prism. Colour deep rose-red. Hardness greater than that of flint spar; does not scratch glass. Some of the faces are brilliant, others often dull and tarnished. Specific gravity 3-44. Found at St. Marcel in Piedmont. Analysis, by M. Delasse: Silica, 50-40; oxide of iron, 34-30; peroxide of iron, 15-95; proteoxide of manganese, 9-62.

Greenstone occurs in small amorphous crystalline masses. Primary form a doubly oblique prism. Colour deep rose-red. Hardness greater than that of flint spar; does not scratch glass. Some of the faces are brilliant, others often dull and tarnished. Specific gravity 3-44. Found at St. Marcel in Piedmont. Analysis, by M. Delasse: Silica, 50-40; oxide of iron, 34-30; peroxide of iron, 15-95; proteoxide of manganese, 9-62.

Greenstein. [Zeolites, P. C.]

Gondalite. [Lead, Ores of P. C.]

Green Iron Earth (Hydrochlorite) occurs in reiform, botryoidal, and globular masses. Colour green, passing into black and yellow. Lustre resinous and dull. Brittle. Found at Selmouth in Saxony. Analysis by Muller: Silica, 56-17; oxide of bismuth, 15-05; alumina, 14-65; oxide of iron, 10-54; phosphoric acid with traces of manganous, 5-62.

brilliant. Structure radiated, crystalline. Streuk and powdery black. Specific gravity 6'29 to 6'32. Found in the coalmines at Hacena in Sweden. Analysis by Setterberg: Sulphuret of lead, 40'36; sulphate of bismuth, 39'18; sulphuret of molybdenum, 12'78; iron, 7'42; sulphate of copper, 1'08; guine, 1'45 to 1'99.

**KOLBITTE (Hydrous Silicate of Alumina)** occurs massive, Colour white. Fracture earthy. Nearly opaque. Lustre submetallic, earthy, with a greenish tinge. Translucent. Perfect cleavage parallel to the faces of the rhomb; generally in small aggregated and diverging fibrous groups of a pale apple green or verdigris-green colour. Streuk paler. Hardness 1 to 2. Translucent. Fracture perfect. Parallel. Emery, amber, opal. Occurs in the Thuringian Forest. Found at Amsdenburg in Thuringia, and also in the volcanic rocks of Vestaul, in black or greenish blue in crustations. Analysis, by Wallencher: Sulphate of copper, 64'64; copper, 64'77; iron, 0'46; lead, 1'04.

**KAFFERSCHAUM** occurs crystallized. Primary form a right rhombic prism. Secondary form a compact, glassy, transparent, perfect cleavage parallel to the faces of the rhomb; generally in small aggregated and diverging fibrous groups of a pale apple green or verdigris-green colour. Streuk paler. Hardness 1 to 2. Translucent. Fracture perfect. Parallel. Emery, amber, opal. Occurs in the Thuringian Forest. Found at Amsdenburg in Thuringia, and also in the volcanic rocks of Vestaul, in black or greenish blue in crustations. Analysis, by wallercher: Sulphate of copper, 64'64; copper, 64'77; iron, 0'46; lead, 1'04.

**LAMARRITE (Sulphate-carbonate of Lead)** occurs in large crystal masses, often in compact, grey, red or pink. Fracture uneven. Hardness 5'5 to 6'0. Lustre vitreous. Translucent. Specific gravity 3'58 to 3'60. Occurs in Cornwall, England. Analysis, by c. H. Ehrenfried, in Finnand. Analysis, by Gymnich: Sulphate of copper, 44'65; alumina, 38'81; lime, 9'29; potash, 6'58; oxide of manganese, 3'16.

**LAVENDERITE** occurs amorphous. Colour lavender blue. Structure fine parallel fibrous. Streak pale bluish green; luster, earthy; hardness 2-5 to 3-0. Occurs at Annaberg in Saxony, with cobalt and iron ores. Analysis: According to Plattner, it contains arsenic, and the oxides of cobalt, copper and nickel, and water.

Lenzite usually forms a variety of the above, its colour being bluish and greyish white.

**LEONARDOSCHEN** occurs crystallized. Primary form an oblique rhombic prism. Cleavage very perfect, parallel to the lateral planes. Strongly colored. Colour bluish white. Fracture uneven. Found at Wolfstein in Rhenish Bavaria. Analysis, by Dr. Delf: Silica, 50'128; alumina, 22'980; lime, 0'261; water and loss, 11'641.

**LEOBERTIT** occurs in large but not perfectly developed crystals in the form of the rhomboid. Colour yellowish in masses, but in thin lamina white. Texture lamellar. Lustre pearly. Transparent in small crystals. Hardness between calcareous and talc. Streak grey. Specific gravity 2'71. Found in the Schiebelmühlen mines in the district of Slaton. Analysis, by Kornmuller: Silica, 34'23; alumina, 16'81; magnesia, 35'60; potezide of iron, 3'38; lime, 9'56; water, 19'86.

**LIEPHDIT** occurs in four-sided prisms, but is seldom regularly crystallized. Cleavage imperfect in three directions. Colour pale dirty green and deep wine yellow. Translucent and transparent. Fracture perfect. Colour develops on cleavage surface. Hardness 5'50 to 6'7. Specific gravity 2'974. Found at Langeland in Norway. Analysis, by J. E. M. J. A. Lund: Silica, 47'82; calcium, 11'51; lime, 25'00; ferric, 6'17; sodium, 7'65; potazide of manganese, 1'01; potassium, 0'26.

**LUGITE** Primary form an oblique rhombic prism. Colour apple green. Streuk greyish green. Fracture uneven. Hardness above 5'5. Lustre of the surface of fracture, between vitreous and resinous. Fracture imperfect. Specific gravity 3'49. Found on the banks of the Stura, in the Apennines of Liguria. Analysis, by J. E. M. J. A. Lund: Silica, 57'45; alumina, 7'86; iron, 20'6; potazide of magnesium, 11'56; oxides of iron, 3'00; oxide of manganese, 0'5 = 56'17.

**LUMB, OXALATE OF** occurs crystallized. Primary form an oblique rhombic prism. Colour deep amarue blue. Streak pale blue. Fracture uneven. Hardness 2'5 to 3'0. Lustre vitreous or adamantine. Transparent, translucent. Specific gravity 3'5 to 5'4. Found at Linares in Swain, and at Lead Hills, Scotland. Analysis, by Brook: Sulphate of lead, 74'4; oxide of copper, 18'00; water, 25'00. Analysis, by J. E. M. J. A. Lund:

**LUNENBURG** Primary form a right rhombic prism, occurs in octahedral crystals. Cleavage parallel to the primary planes. Colour light blue and occasionally dull green. Streuk in various directions. Hardness 2 to 2'5. Transparent, translucent. Specific gravity 2'926. Found near Redveth, Cornwall, and in Hungary. Analysis, by Dr. J. E. M. J. A. Lund: Arsenic acid, 43'89; oxide of copper, 30'10; water, 26'03.

**LITHOMORCHE** occurs massive. Spheroideal. Colour white, grey, red, yellow, blue. Streuk shining. Structure compact. Soft. Dull. Opaque. Utenous to the touch. Adheres to the tongue. Specific gravity 2'2 to 2'5. Found in Cornwall near Redruth, in Saxon and some other places in Europe. Friable Lithomorche occurs in scaly, glimmering particles, which are phosphorescent in the dark. Found at Ehrenfried-derdendorf in Saxony, by Klaproth: Silica, 32'00; alumina, 26'50; oxide of iron, 21'00; chloride of sodium, 1'50; water, 17'00.

**MAGNIES** ALUM occurs massive. Structure fibrous, also compact. Colour white. Streuk snow white. Fracture uneven. Found at Cape Verde, in Southern Africa, where it covers the floor of a grotto to the depth of six inches. Analysis, by J. E. M. J. A. Lund: Sulphate of alumina, 38'998; sulphate of magnesia, 10'890; chloride of magnesium, 4'927; chloride of potassium, 0'025; water, 45'780.

**MAGNIES, HYDRE OF.** (Sheppard.)

**MAGNIES, FRASMCOLITE occurs massive. Cleavage foliaceous. Colour brown, transparent. Found in one listed in a directory of brown clay. Streuk pale brown and grey. Streuk white. Fracture uneven. Frequently coated with brownish or black powder. Hardness 3'0 to 3'5. Lustre pearly, especially on perfect cleavage planes; on the fracture surface, vitreous. Colour varies from iron to yellowish brown. Specific gravity 2'25. Found near Wolfsstein in Rhenish Bavaria. Analysis, by Dr. Delf: Silica, 50'128; alumina, 22'980; lime, 0'261; water and loss, 11'641.
Lustre generally terminated by lanthanum, consists of the protoxide of oxygen, magnesia, water, sulphuric acid, chalk, and sometimes perpendicularly to the axis. Fracture not observable. Hardness of the cleavage surfaces 2-0 to 2-5, that of the edges 4-5 to 5-5.

**Rhomboedral Mica**. Primary form an oblique rhombic prism, according to Breseke the preceding descriptions will probably apply to this variety, except as to the form.

**Oblique Prismatic Mica**. Primary form an oblique rhombic prism, and according to Breseke the preceding descriptions will probably apply to this variety, except as to the form.

**Magnetite**. Primary form a rhombic prism, sometimes tetragonal, perpendicularly to the axis. Fracture not observable. Hardness of the cleavage surfaces 2-0 to 2-5, that of the edges 4-5 to 5-5.

**Middletonite**. Occurs in rounded masses, seldom larger than a meter in diameter, and usually in a mass of thin shining laminae. Primary form a rhombic prism, showing a bright red colour by transmitted light. Fracture parallel to the axis.

**Monadrite**. Occurs massive. Fracture, one distinct, and another imperfect. Colour pale yellowish, verging on red. Hardness nearly that of felspar. Lustre vitreous. Specific gravity 2-98. Found at Bergen, in Norway. Analysed by Erdmann: Silica, 56-17; magnetite, 31-82; protoxide of iron, 8-66; water, 4-04.

**Monticellite**. Occurs crystallized. Primary form a right rhombic prism. Cristalline, and have usually the aspect of quartz. Colour generally yellowish. No cleavage planes have been observed. Hardness 5-0 to 6-0. Sometimes nearly transparent and colourless. Found at Venustia. It has not been analysed.

**Monambrites**. Occurs massive and fibrous, and crystallized in flat prisms. Cleavage in one direction distinct, in others indistinct. Colour dull reddish-brown. Lustre greyish brown. Hardness 4-0. Lustre of cleavage face between vitreous and greasy; of other surfaces resinous. Thin splinters translucent and showing a bright red colour by transmitted light. Specific gravity 2-98 to 2-98. Found at Lammansker in Sweden. Analysis: according to Erdmann. It contains about 10-0 per cent. of silica, titanic acid, and the oxides of iron and lanthanum, with some oxide of manganese, lime, a little magnesia, potash, and water.

**Nickel Oxide**. Occurs crystallized in acicular four- or six-sided prisms, indistinctly terminated and longitudinally striated. Cleavage parallel to the axis of the prism. Colour, when first broken, steel-grey or blackish lead-grey, soon acquiring a yellowish or olive-green tinge. Lustre dull to resinous, with a shining metallic lustre. Hardness 2-0 to 2-5.Opaque. Specific gravity 6-15. Found near Ekaterinburg in Siberia. Analysis, by Frick: Sulphate, 11-58; bismuth, 43-20; copper, 12-10; nickel, 1-68; tellurium, 1-32.

**Nephelite**. Occurs in crystals, which are elastic, sometimes curved, and easily separated. Colour white, with a shade of yellow. Lustre white. Lustre highly silky. Opaque. Some decomposed varieties have an earthy appearance. Hardness 2-0. Specific gravity 2-535. Found in veins at Hoboken, New Jersey, and other places in the United States. Analysis, by Dr. Thomson: Silica, 56-568; magnesia, 51-721; peroxide of iron, 5-874; water, 20-696.

**Numerolite**. Occurs in crystals, which are almost lenticular. Primary form a rhomboid. It is generally found implanted in mammillated masses. Colour yellow, greyish or greenish. Lustre white, yellowish white or greenish. Fracture somewhat conchoidal. Hardness 4-0. Lustre greasy, feeble. Specific gravity 4-0415. Found in the mines of Nysse, near Bingen, departmen of Bavaria. Analysed by Rhine, Frieden: Lubricity of lead, 50-50; phosphate of lime, 22-95; chlorite of lead, 7-56; arsenide of iron, 6-50.

**Oberhutite**. Occurs crystallized. Primary form a right square prism. Cristalline, and have usually the aspect of quartz. Colour generally yellowish. No cleavage planes have been observed. Hardness 6-5. Specific gravity 2-68. Found at Arendal, Norway. Analysis: Titanate of zirconia, 68-956; silica, 19-708; lime, 2-612; magnesia, 2-047; protoxide of iron, 1-136; water, 5-332.
Oxide (Dycodite) occurs in fibrous masses, having a radiated structure; also imperfectly fibrous, or composed of minute crystals. Hardness 4.5 to 5. Colour white. Specific gravity 2.28. Translucent. Exhibits double refraction. Found at Bobile: Silica, 56.99; lime, 26.35; water, 16.65.

Oleodraca occurs crystallized. Primary form an oblique rhomboid. Colour grey, white, or yellow. Fracture obscure, uneven. Hardness 4.0. Transparent. Sub-translucent. Specific gravity 2.64 to 2.07. Found at Danviksoll near Stockholm, Arendal in Norway, etc. Analysis, by Bernelius: Silica, 65.70; almina, 20.95; lime, 9.26; magnesia, 0.65; soda, 8.11; potash, 1.95; peroxide of iron, 0.50.

Olivins. [Amethyst, P. C.]

Oxalate of Iron. [Iron. Oxalate of.]

Oxalate of Iron. [Talc. Silicate of.] Found near Otter on the borders of Luxembourg. Analysis, by Damour: Silica, 43.34; alumin, 24.63; project of iron, 16.72; project of manganee, 8.18; water, 6.66.

Oxalate of Iron. [B. of Hydrogen]. Colour yellowish brown. Translucent. Has a slight bituminous odour, and softens by the heat of the hand, so that it may be kneaded. Fuses readily, emitting a stronger bituminous odour; burns with a clear bright flame without residue. Insoluble in water, only slightly in alcohol, but readily in ether and oil of turpentine. Found in considerable masses at Slanik in the Buchan district of Moldavia, and used for fuel. Analysis, by Carbon, 85.204; hydrogen, 19.767. It appears to be similar in composition to Hattichetine.

Paragaste. [Augeite, P. C.]

Pectinite occurs on spheroidal masses which have a radiated structure. Found at Wolfsberg in East Tyrol. Analysis, by Darley: Hardness 4.0 to 5. Lustre pearly. Nearly opaque. Specific gravity 3.69. Found in large masses on Monte Baldo, in the Southern Tyrol, and at Monzoni in the Fass-chal. Analysis, by Von Frey: Silica, 49.78; soda, 20.08; potash, 1.57; alumin and oxide of iron, 9.05; water, 3.89.

Periclase occurs crystallized on regular octahedrons. Primary form a cube. Cleavage in three directions parallel to the faces of the cube. Colour obscure green. Hardness equal to felspar. Lustre vitreous. Translucent. Specific gravity 3.78. Found in the lava of Venedos. Analysis, by Damou: Magnesia, 92.37; oxide of iron, 6.91; insoluble matter, 0.86.

Pharmacolite. [Magnesian Pharmacolite.]

Schwartzeneb in Saxony, and Frankish, North America. Analysis, by Bernet: Arsenic acid, 38.00; peroxide of iron, 40.56; phosphoric acid, 0.70; oxide of copper, 0.50; water, 19.37; insoluble matter, 0.05.

Pharmacolite occurs crystallized. Primary form a rhombohedric, Cleavage parallel to the primary faces. Colourless; also bright yellowish, inclining to red. Hardness above 6. Lustre vitreous. Transparent to opaque. Specific gravity 2.699. Found near Freiberg and near Framont. Analysis, by Hartwell: Silica, 55.14; glumea, 44.47; alumin and magnesia, 0.39.

Phlogopite, a hydrous silicate of aluma, probably similar to halloysite.

Phosphorite. [Apatite, P. C.]

Phylite. [Gigantolite?]

Pickcrivite (Magnesia Ahorn) occurs in masses composed of long parallel fibres of a silky or satin lustre. Colour white, or, viewed in the direction of the fibre, pale rose-red or light green. Compact, but easily divided parallel with the fibres. Brittle. Specific gravity 1.78 to 1.80. Found at Tarapaca in Peru. Analysis, by Stroemer: Sulphuric acid, 36.770; alumin, 11.515; magnesia, 3.890; peroxide of manganese, 2.617; dioxide of potassium, 0.025; water, 45.739.

Phricite. [Turquoise, P. C.]

Pimente. [Nickels, Ore of. P. C.]

Pigoure occurs massive. Colour siskin or oil green; streak light grey. Fracture conchoidal or uneven. Hardness 2.5 to 3. Lustre imperfectly conchoidal. Found at Wullenstein in the Erzgebirge. Analysis, by Kertel: Silica, 30.80; peroxide of iron, 0.978; water, 64.20; Ferroalumina (Oxide of Iron) occurs in crystalline masses and crystallized. Primary form an oblique rhombohedral prism. Colour bronze-yellow; streak black. Fracture conchoidal, uneven. Hardness 5-6. Lustre metallic. Specific gravity 7.288 to 3.082. Found at the Jungfer mine, Moien. Analysis, by Platten: Arsenic, 39.707; nickel, 57.044; cobalt, 0.880; copper, 0.892; sulphur, 0.817.

Pleister Slate (Poker Slater) occurs massive, with a shaly texture. Colour white, yellowish white, or yellow. Brittle. Opalite. Specific gravity 0.99. Found near Billo in Bohemia, at Zwackau in Saxony, and Auvergne, and is supposed to be a volcanic product. Analysis, by Buchola: Silica, 83.50; alumin, 4.00; lime, 8.80; oxide of iron, 1.50; water, 9.00.

Phlogopite occurs crystallized in long slender crystals. Primary form a right rhombohedral prism. Fracture uneven, opaque. Hardness 3-5. Lustre vitreous. Found at Poons in the East Indies. Analysis, by Gurnem: Silica, 45.120; alumin, 50.446; lime 10.197; soda with a trace of potash, 0.657; water, 18.886. Found at Poons (Talc. See Pheg.•)

F, (Quartz, P. C.]

Phegolite occurs imperfectly crystallized in prisms of several sides, with the edges rounded. Cleavage in one direction. Colour brown or dark brown; streak clear green. Fracture splintery and flat conchoidal. Hardness 3-5. Lustre weak. Specific gravity 2.754. Found near Brevig, Norway. Analysis, by Ermann: Silica, 49.94; alumin, 28.70; proto-
axide of iron, 6-06; protorside of manganose, 0-92; magnetite, 18-73; tianiic acid, 9-40; oxode of lead, copper, and cobalt with lime, 0-50; water, 3-78.

Praseolite occurs massive. Composed of loosely adhering fibres. Colour dark leek-green. Hardness not sufficient to scratch porcelain, but can be scratched by the fingers. Specific gravity 2-311. Found on the Killpatrick Hills. Analysis, by Dr. Thomson: Silica, 34-55; magnetite, 15-85; peroxide of iron, 14-90; alumina, 2-05; lime, 2-55; oxode of manganose, 1-20; water, 18-00. The loss amounting to 3 per cent, is attributed to an alkali.

熳 transcript. (German); purchased from the Comte de la Hydriae. (Hydriae of Magnesia) occurs in masses which are imperfectly crystallized, or present a foliated structure and crystallized. Primary form a right rhombic prism. Cleavage parallel with the primary planes imperfect. Colour brown or ochreous-brown, yellow or brown; streak yellowish grey. Hardness 4-0 to 4-5. Lustro metallic, pearly. Translucent, opaque, in thin laminae sometimes transparent. Specific gravity 3-07 to 3-10. Found on Orange County, New York, near the village of Amity. Analysis, by Clemson: Silica, 17-0; alumina, 37-0; magnesia, 24-3; lime, 10-7; protorside of iron, 0-5; water, 2-60.

Siderolite (Hydriae of Magnesia) occurs rarely in hexagonal prisms, generally in laminar masses, and fibrous. Primary form a rhombohedron. Colour white, greenish white. Steack white. Lustro pearly. Transparent, translucent. Hardness 1-0 to 1-5. Specific gravity 3-26 to 2-54. Found at Inverness, in New Jersey, New York, and in the island of Unat, Scotland. Analysis, by Bruce: Magnesia, 70; water, 30.

Smaragdite. [Amphiroolith, P. C.]

Silrislite. (Zinc, Ores of P. C.]

Saprolite (Hydriae of Magnesia) occurs crystallized and massive. Primary form a square prism. Cleavage perpendicular to the axis, very distinct. Colour pale dull brownish-yellow. Fracture uneven. Transparent, translucent. Found in the cavities of material ejected from Vesuvius. Analysis, by Monticelli and Covelli: Silica, 43-96; lime, 31-67; magnesia, 8-83; alumina, 0-90; protorside of iron, 2-00. Kobell found 4-25 per cent. of soda.

Soda Alum occurs in white fibrous masses. The outer fibres opaque by decomposition, internally transparent and exhibiting a glossy or silvery aspect. Not scratched by the nail. Specific gravity 1-83. Found at St. Juan in South America. Analysis, by Thomson: Sulphuric acid, 38-5; alumina, 12-0; soda, 7-5; water, 42-0; with a little silica, lime, iron, and manganose.

Soda Alumicite. (Monticelli, Somervullite (Humoludite) occurs crystallized. Primary form a square prism. Cleavage perpendicular to the axis, very distinct. Colour pale dull brownish-yellow. Fracture uneven. Transparent, translucent. Found in the cavities of matter ejected from Vesuvius. Analysis, by Monticelli and Covelli: Silica, 43-96; lime, 31-67; magnesia, 8-83; alumina, 0-90; protorside of iron, 2-00. Kobell found 4-25 per cent. of soda.

Sphaerolite (Kreutler, Extr.) Humboludite of Monticelli, Somervullite (Humoludite) occurs crystallized. Primary form a square prism. Cleavage perpendicular to the axis, very distinct. Colour pale dull brownish-yellow. Fracture uneven. Transparent, translucent. Found in the cavities of matter ejected from Vesuvius. Analysis, by Monticelli and Covelli: Silica, 43-96; lime, 31-67; magnesia, 8-83; alumina, 0-90; protorside of iron, 2-00. Kobell found 4-25 per cent. of soda.

Sphalerite. (Zelligite, P. C.)

Strebenite occurs crystallized and massive. Primary form a right rhombic prism. Colour pink or brownish, with occasionally a violet tints in some of the masses. Sphalerite.

Strebenite occurs crystallized and laminar, and fibrous masses. Cleavage in one direction, 3-9. Spiney to black. Streble glands to live brown. Lustre vitreous. Hardness 3-0 to 4-0. Specific gravity 3-27 to 3-4. Found at Obergund and Linnzamnelt, in Silene. Analysis, by Ramsellberg: Silica, 46-00; protorside of iron, 53-89; water, 7-100; lime, 0-577; protorside of iron, 1-888; water, 7-00; 97-41.

Stilbomelan occurs crystallized, lamellar, and fibrous masses. Cleavage in one direction, 3-9. Spiney to black. Streble glands to live brown. Lustre vitreous. Hardness 3-0 to 4-0. Specific gravity 3-27 to 3-4. Found at Obergund and Linnzamnelt, in Silene. Analysis, by Ramsellberg: Silica, 46-00; protorside of iron, 53-89; water, 7-100; lime, 0-577; protorside of iron, 1-888; water, 7-00; 97-41.
Specific gravity 6-2 to 6-4. Found at Lead-hills, in Scotland. Analysis, by Brooke: Carbonate of lead, 72-5; sulphate of lead, 27-5.

**SILICA** (Haryhototriaanite). [**SILICA**, P. C.]

**STrias**. [**Wolfsberg**, P. C.]

**Tillumtbnsten** (Turtle of Bismut). [**Tellium**, Ors, of P. C.]

**Tthrine** occurs crystallized and massive. Primary form a right rhombic prism. Massive variety has a crazily lamellar or crystalline structure, with cleavages parallel to the planes of a right rhombic prism. Colour greenish grey, Streng greyish white. Hardness 6-0. Translucent in thin pieces. Specific gravity 3-60. Found at Bodenmais, in Bavaria. Analysis: Phosphoric acid, 41-47; protosilicate of iron, 48-27; protosilicates of manganese, 47-0; laths, 5-40; silica, 0-53; water, 0-36.

**Vauqulieite**. [**Chromit, Ors, of P. C.**]

**Wackerite** (Phosphatc of Magnesia). Primary form an oblique rhombic prism. Fracture uneven. Colour yellow, or different shades; often greyish. Streng white. Hardness 6-0 to 5-5. Lustre vitreous. Translucent. Specific gravity 3-11. Found in the valley of Holghare in Salzburg. Analysis, by Fuchs: Phosphoric acid, 41-73; hydrofluoric acid, 6-50; magnesia, 46-06; oxide of iron, 5-00; oxide of manganese, 0-95.

**Wakewite** (Fluoride of Titanum and Iron). Primary form an oblique rhombic prism. Fracture parallel to the longer diagonal, perfect. Colour dark brown to iron grey, and often with a copper-red tinge on the face of perfect cleavage. Decomposing crystals are nearly iron black, with a faint tinge of purple. Fracture uneven. Hardness 5-5 to 6-0. Brittle. Lustre metallic-pearly on the cleavage surface; of other surfaces, vitreous or subvitreous, often nearly dull. Specific gravity 3-0 to 3-29. Found near Amity and Enderville, in the State of New York. Analysis, by Sheephed: Titanum, 64-71; iron, 2-144; yttrium, 0-80; fluorine, 27-33.

**Washingtonite** (Titanite). [**Titanium, Ors, of P. C.**]

**Witkittite**. [**Wilkite**, P. C.]

**Witkittite occurs in oblique rhombic prisms. Colour saligrey or brownish. Presents only feeble traces of cleavage. Fracture even or coarse granular. Hardness, scratchs glass, by nitre. Specific gravity 2-80. Found at Fabian, Sweden. Analysis, by Wechsttiser: Silica, 53-69; alumina, 21.70-; magnesia, 8-99; protosilicate of iron, 1-43; protosilicate of magnesium, 0-68; potash, 4-10; soda, 0-68; oxide of zinc, 0-3; water, with a little ammonia, 3-20.

**Wilkite**. [**Wilkite**, Ors, of P. C.]

**Wittkittite** occurs in angular grains, and in tabular crystals; form undetermined. Cleavage distinct in one direction. Colour light yellow, wine-yellow, honey-yellow, brownish yellow. Streng yellowish white. Fracture more or less conchoidal, splintery. Hardness 5-5. Lustre vitreous. Subtranslucent. Translucent. Specific gravity 3-41. Found in an island near Browin in Norway. Analysis, by Scherer: Silica, 30-62; carbonic acid, 14-47; zirconia, 15-17; lime, 26-19; soda, 7-78; oxide of iron, 2-12; protosilicate of magnesium, 1-55; magnesia, 0-40; water, 0-54.

**Wittkittite occurs in rolled masses, having a foliated crystalline structure, and sometimes presenting very small apparently isolated prisms. Colour white. Opague. Specific gravity 2-12. Lustre vitreous. Translucent. Specific gravity 3-1. Found near St. Petersburg, on the shores of the Bay of Finland. Analysis, by Dr. Hess: Silica, 40-79; alumina, 55-06; magnesia, 0-88; water, 9-88.

**Yttricite**. [**Yttrium**, P. C.]

**Yttrontialite**. [**Yttrium**, Ors, of P. C.]

**Zeagonite**. [**Phillipette**, P. C.]

**Zollite**. [**Zoltite**, P. C.]

**Zollite occurs crystallized and massive. Primary form a cubic or square prism. Cleavage indistinct. Colour asparagengreen, inclining to grey. Fracture conchoidal. Hardness about 6-0. Lustre resinous. Opague. Specific gravity 3-27. Found on Veauville.

**MANES.** Mines. Colour is properly open in the ground from which any thing is dug. Until an opening is made, the name is not properly applied, though the term is now generally used to signify a lead, iron and so forth, before an opening is made for digging out.

Mines belong to the tenant in fee-simple of the land, with the exception of gold and silver mines, which belong to the king by his prerogative, but by 1 W. & M. c. 90, a mine of copper or tin is not to be considered a royal mine, though silver may be extracted from the ore. The owner of land in fee-simple is the owner of everything which lies in a perpendicular direction under the surface to any depth. A tenant for life, unless his estate is without impeachment of waste, cannot dig earth, lime, clay or stone, except for the repair of buildings or the marring of the land. In fact the general principle is that the land, which term comprehends everything in it or that is permanently attached to it, cannot be taken away by any other person than the tenant in fee-simple or a tenant in tail. Accordingly a tenant for life cannot open a new mine, but he may work mines which are already open; and he may open new shafts for working veins of coal which have been already worked. A tenant in tail has an estate of inheritance, and incident to it the power of committing waste, as by cutting down timber or opening mines.

If a man who has a lease in fee-simple in a parcel of land, works the mines upon it, the lessee is thereby empowered to dig for the minerals; if he leases lands on which mines are already open, the lessee may work them.

The freehold is vested in the lord, and it is a legal consequence that he has the freehold of the mines. In some cases a copyholder of inheritance has by the
custom of the man a right to the timber, and the lord has no right to dig mines, unless there be a custom which gives him the right.

A man works mines under his own land and follows the ore on other substance under his neighbour's land, he is a trespasser.

The act 7 & 8 Geo. IV. c. 50, § 7, enact certain punishment for malicious injuries done to mines. [Maurice's P.C.] A partnership for working a mine is subject to the same legal rules as any other partnership. [PARKER, P.C.]

MITCHELL, THOMAS, was born on the 30th of May, 1783, in London, and was the son of a riding-master. At the age of seven he was admitted into Christ's Hospital, where he remained the year 1802, when he went to Pembroke College, Cambridge, on one of the exhibitions of the Hospital. In 1806 he took his degree of B.A., and the distinguished manner in which he acquitted himself at college induced the governors of Christ's Hospital to present him with a handsome silver cup. He did not however obtain a fellowship, as he had hoped, for no more than two persons educated at the same school are allowed to hold fellowships in Pembroke College at the same time. This regulation, which was then made and carried into effect for the first time, dammed all Mitchell's schemes, who had determined to devote himself to philosophical pursuits. A few years afterwards however he obtained as a scholar-ship at Sidney Sussex College, Cambridge, Mitchell never married, and if he had taken holy orders he might have remained in the enjoyment of that fellowship for life, and would have become a learned and elegant writer, to which he was afterwards exposed. But he never took orders from a fear of the great responsibilities of the pastoral office, and consequently, after a limited number of years, he was obliged to resign the statutes of the college to vest in his fellowship.

He afterwards earned his livelihood by private tuition and by writing for the press: he was engaged for ten years as tutor in private families. In 1818 he commenced a series of essays for the Quarterly Review on Aristophanes and Athenian satirists, and this led him to translate some of the plays of Aristophanes into English verse: his translation appeared in 2 vols. 8vo., 1820-22. His articles in the 'Quarterly Review' impressed the patron of a vacant Greek chair in one of the Scotch universities with so much respect for his classical attainments, that they invited him to accept the situation; but as he would have had to sign the Confession of the Scotch Kirk, which was to him an insurmountable obstacle, he declined the lucrative office, notwithstanding his poverty. During the last twenty years of his life Mitchell lived with some of his relations in the county of Oxford, and occasionally superintended the publication of his works, which he had commenced time printed at the Clarendon press. During the years 1834-88 he edited, in separate volumes, five of the plays of Aristophanes, with English notes; and in 1839 he began an edition of the plays of Sophocles likewise with English notes; but as soon as the first three tragedies had appeared, the publication was suspended in 1842, because English notes were thought objectionable; and Mitchell now had no other employment but what the Clarendon press might casually offer. The almost entire cessation of literary income not only caused him great pecuniary difficulties, but broke down his health and spirits. His friends became alarmed about him, and made his condition known to Sir Robert Peel, who immediately placed at his disposal the sum of £500, from the royal bounty fund. In 1848 the publication of Sophocles was resumed, and the remaining four plays were likewise edited by Mitchell, though with his notes than the preceding three. In 1844 he undertook the publication of a minor edition of a 'Pentalogia Aristophanica,' with short Latin notes, and had nearly completed his task when he died suddenly, on the 5th of May, 1846, at his house at Steeple Aston near Woodstock. His health had long been in a weak state, but his death was unexpected.

The works which Mitchell edited and commented upon are those that he was a Greek scholar of considerable eminence; but his notes are often irrelevant, and the text of his author is seen to furnishing opportunities of showing his strong political opinions: he had a passionate antipathy to the popular democracy and democratic forms of government in general. (Classical Museum, vol. iii. p. 213, &c.)

MITFORD, WILLIAM, the eldest son of John Mitford, Esq., of Exbury in Hampshire, was born in London on the 10th of February, 1744. In his boyhood he spent some time at Eton, and was kept at Chevening Park by the well-known Mr. Gilpin, who afterwards owed him the living of Boldre. Ill health caused his removal from school about the age of fifteen; and it seems to have been with very insufficient preparation that he became a scholar in Pembroke College, Oxford. His time at the university was idly spent, and he left it without taking a degree. Perhaps the most important influence exercised on his mind by his academic residence was derived from the Vinegar Stone, which he attended regularly. He studied law for a time in the Middle Temple, but found the study distasteful; and, having succeeded to the family estate in 1761, on his father's death, he abandoned the legal profession and became Lord Redesdale. In 1766 Mr. Mitford married; and for seven years afterwards his time was chiefly spent in the retirement of his country-seat, where his early predilections for the Greek language and literature grew into a settled passion. In 1769 he became a captain in the South Hampshire militia, of which the historian Gibbon was then major; and the conversation and advice of Gibbon confirmed, if they did not prompt, his resolution to undertake a history of Greece. His first work, 'An Inquiry into the Principles of Harmony in Languages, and of the Mechanism of Verse, Modern and Ancient,' appeared in 1774, and was followed in 1776 by his first and most important book, published 'A Treatise on the Military Force, and particularly the Militia, of this Kingdom.' In 1776 he lost his wife, and was himself seized with a dangerous illness, on his recovery he was given the charge of New Forest. Before leaving home he had become acquainted with the French scholars Voltaire and De Meunier: the former introduced him to the Baron de Saint Croix; and his intercourse with these young and brilliant students matured his own literary ambition. On his return home, however, he allowed public duties to claim frequent precedence. He acted as a county magistrate, and in 1778 was appointed Verderer of the Western Forests, and in 1784 commissioned to Gibbon's lieutenant-colonelcy in 1779, and in 1805 was appointed to the colonelcy, which he resigned in the course of the next year. From 1785 till 1790 he sat in the House of Commons as member for Newport in Cornwall; from 1796 till 1806 he represented Beeston, a nomination borough of his maternal kinsman the Duke of Northumberland; and from 1812 till 1818 he was member for New Bemom. His parliamentary career was confined to two or three speeches on the militia laws. In 1802 he succeeded, through his mother, to the Revels estates in Yorkshire. But his paternal estate on the borders of the Welsh Marches was his particular residence. He died there on the 8th of February, 1827.

His 'History of Greece' was written and published in successive portions, the dates of the first edition, in quartos, being 1774, for the first three volumes; 1790; and 1851, for the following ones. His 'History of Britain' was also published in several portions; the first, for the years 1700; vol. iii., 1797; vol. iv., 1808; and vol. v., 1818. It closes with the death of Alexander the Great; and the author, enfeebled by age and partly blind, was unable to execute his intention of continuing it to the subjugation of Greece by the Romans. In 1815 appeared an octavo edition of the volumes which had previously been published; and in 1892 there appeared a new edition of the whole work, in eight octavo volumes (since reprinted), with an introduction by his brother, Lord Redesdale, furnishing some particulars of the author's life, but chiefly taken up in vindicating the political opinions expressed in the work. These opinions have been exposed Mr. Mitford's 'History' to much animadversion. It is determinedly anti- democratic; and this turn of thinking affects seriously the fairness of the estimate which it forms both of characters and of events. His partiality is especially palpable in his account of the war between the Greeks and Pharaoh of Macedon. Philip is with him a perfect king, hero, and statesman. Demosthenes is a dishonest and malignant demagogue, and the Athenians are a horde of treacherous mercenaries. Yet the author's researches are the result of long and careful reading, and as such are looked upon as other parts of Grecian antiquity. He has elucidated with remarkable success the state of political parties in some of the severest struggles of Greek politics; and he has suggested new and very accurate views of several other points. He has been led to these results mainly by his severely critical way of estimating the ancient authorities, and by his systematic endeavour to gain his knowledge from cor

MODELLING. Modelling in clay is so completely a practical art, and depends so much on the experience and formative skill of the modeller, that beyond a few remarks on the necessary consistency of the clay, nothing more can be given here than a sketch of the nature and uses of the tools, and some description of the sculptor's process.

The tools, called modelling tools, are made of wood and wire, but no tool is more useful than the finger; indeed tools have been invented as mere aids to modelling a bust, and agreed only to do what they cannot perform. Wire tools are the most useful, being fashioned into loops of various shapes and sizes, round and angular, and fixed into wooden handles. They accomplish any required form without driving the clay, and are especially useful for shaping the superfluous clay remaining in its place while the wire passes under it and until the tool is removed, when it either falls of its own weight, or is removed by the slight rubbing of the modelling tool in making the creases. These wire tools are the most useful when applied to concave surfaces, especially those in the close or narrow folds of drapery, the wire being sometimes notched or indented, to give a rough surface to the clay, and it can be used to form box and eddy, of various shapes and sizes, curved, straight, pointed, rounded, and flat and broad; the broad tools being notched, and designed chiefly for working the large convex masses, or large folds in drapery. The bar tool, or the tool of adhering clay will drive up the surface. A good method to guard against this accident is to keep the wooden tools which are used for the finer work soaked in oil; the clay is then not liable to adhere, and much time is accordingly saved in finishing the model. The above is perhaps, without practical demonstration, all that can be usefully said about the working tools.

The clay used is common potter's clay, but should be of the best quality. It must be so wet that it will not stand in a mass much larger than its own width without support. The clay adheres much more to the tools when wet, but it is at the same time harder, and quite worked, a matter of great consequence, as the patination of the artist less tried, and some expenditure of time is saved. The supports for the clay are a most important consideration, for if not well chosen, or if the clay is not firmly adhering to them, a weight of 6 months of labour, might suddenly fall to pieces by its own weight. This accident happened to Don Jose Alvarez, a celebrated Spanish sculptor, while at Paris. He modelled, about the year 1805, a colossal statue of Achilles receiving the fatal arrow into his heel, which, owing to the insufficient support of the clay, fell to pieces shortly after it was finished; it was much admired by the connoisseurs of Paris, but Alvarez had not courage, or waited opportunity, to restore it. This accident might certainly have been prevented by proper attention to the supports of the clay while the model was in progress, for though in large models this is a work of great care and labour, it is always preferable the support of a figure of the heroic or ordinary size (seven feet) is comparatively easy, but this also exacts strict attention, especially if in any very active or unusual attitude. Sculptors generally model figures of the ordinary size upon a bench, a stand or a chair, about thirty inches high, and thirty inches square,—for a bust it must of course be much higher; above this a solid circular plinth is fixed on a wooden box, and is supported by a strong arm. It may be better to use short slightly conical rollers, fixed to the plinth near the circumference; the plinth moves easily on such rollers than wheels, and the rollers afford a more solid support and last than when diminished or removed. The sculptor must be able to see his work on all sides, in any light, and it enables him to work on all parts, in one spot, or in the same light. On the centre of the plinth there must be fixed vertically a strong iron bar, about the height of a man, and from about six to ten inches in circumference, according to the weight of the figure; it must necessarily be strong and firmly fixed in the ground, as it is the main support of the whole skeleton of supports. In loosely draped figures which are to be removed, it is advisable to fix a vertical beam of wood to the main iron bar; for though the bar will keep the clay perpendicular in its place, it is no provision against the sinking of a great mass, and the quantity of clay; for some figures, even of a miniature size, only, amounts to about two tons. Two or three pieces of wood must be fixed to the main bar at the shoulders and the loins, from which the supports of the arms and legs must be started; and a third piece, fixed in the same manner, is to be provided to support the weight of clay: the supports of the legs must be bars, straight or bent, according to the position of the legs; but the supports of the arms, when not detached from the body or drapery, may generally be made of twisted thick cooper wire, small pieces of wood being twisted in with it at short intervals and at right angles, like the pieces of paper in the tail of a boy's kite. The fingers, if separated, will require similar care; indeed the clay should be gradually built up against a complete skeleton of supports, and sufficiently strong not to yield in the least to the weight of the clay when the model is finished. The building of such a skeleton for a figure of the heroic size is often so great a work that it would be advisable to always provide a young sculptor, in modelling his first figure, to procure some experienced hand to construct such a skeleton, as it is more easily elevated and detached from the figure, the supports of the arms, and it would be almost impracticable to allow the arm to be removed at pleasure, which would enable the sculptor to model the part beneath it with much greater ease, and diminish the risk of injury to the arm. The contrivance is easily accomplished, for nothing more is required than a pipe or tube in the shoulder support, which could receive and hold firmly the metal arm, which could be fixed in the plinth by a bar of wood or metal; or merely thick or twisted wire, when of a smaller size. In modelling a bust very little support is necessary, an upright piece of wood with a cross bar at the shoulders being quite sufficient; but a small cross bar at the head would do no harm.

Another essential part of modelling is preserving the moisture of the clay, which should be always uniform if possible; it must never be allowed to dry, and it can be kept moist with very little trouble. While the modeller is at work, the figure is exposed, especially in warm weather, he should repeatedly sprinkle it with water. A plasterer's brush is the best instrument for this purpose, and much superior to a syringe or the mouth, which some sculptors formerly used to apply as a squirt, even in the presence of their sitter, when modelling a bust; Nolleken's, according to his biographer on account of the great efficacy of his hands, never ceased to use it. Bojon, a sculptor who modelled the bust of George III., and in the king's presence, Bacon, on a similar occasion, used a silver syringe. At night time, or when the artist is not at work on the model, the air may be kept moist for a long period without adding water, provided the air be kept away from it; this may be done by an oil-silk or any air-proof bag, which can be made fast to the plinth of the banker by clay. Sculptors generally model flowing drapery from lay-figures. When the model is complete, the next process is to take the cast, to work the marble from, or to make other casts from. The whole model, while wet, must be covered, in two or three masses, or more if necessary, with plaster of Paris; when this is fixed and dry, the whole may be separated at the joints, without any regard to the preservation of the model, for when the mould is taken off, and before it is allowed to dry, it may be again, and completely removed from the mould, the component parts of the mould must be again put together, and in the place of the original clay it must be filled with plaster of Paris, and when the cast is set well, the mould may be taken off, the lining of the cast removed in fragments, and the cast is exposed, and complete, the finished work. If casts of it are required, a new working mould, or safes mould, as it is termed, must be taken, in two or three masses; and in the same manner the cast is copied by the carvers, with the assistance of the pointing-machine, of which the most complete is that invented and used by W. C. Marshall, A.R.A. It is so contrived that it can be turned to any side, and in a mass of figures, even in small ones, it is practicable, because any error in VOL. II.—2 8
a small model becomes multiplied in a larger one in proportion to the difference of size. Flaxman was in the habit of making small models, and he had in consequence sometimes immense labour to go through to diminish errors in the full-sized marble work: it is hardly possible to completely rectify these.

The antient sculptors used to bake their models, but this is not so good a plan as making plaster casts from them, though less troublesome and much cheaper: the clay in drying shrinks, and is apt to crack, and certainly never comes out of the oven the same shape that it was when put into it, or at least when originally modelled. These baked models are called termo-cotta (baked bath) figures, are extremely numerous, and are generally of small dimensions, but there are a few of a large size in various European museums. There are four at Naples which were found at Pompeii; and the inferiority of these works is some proof of the advantage of the modern method of taking plaster casts from the models over the antient system of baking them, for the errors in the proportions of these works are probably to a great extent due to the shrinking of the clay in the oven. The antients made also moulds of clay, which they likewise baked, and they formed their casts by the pressure of clay into these: this practice of pressing clay, or any malleable substance, into a mould is still occasionally, and recourse to it is found of rare art, as constantly in the potteries, and by frame-makers.

The antients used also wax for casting and in forming their models, especially those of the small bronzes, which are still so excellent, and recouered to in works of full art, as constantly in the potteries, and by frame-makers.

MOLYNIA, a genus of grasses belonging to the tribe Festucineae. It has unequal glumes without lateral ribs, shorter than the lanceolate spikelet of 3 or 3 sessiletridical-
flowers and a series of small palisading on the loose fruit, and the styles terminal. There is one species which is British—

M. cornua, which has an erect elongate narrow panicellate, spikelets from 1- to 3-flowered; the outer palea rarely 5-

denned, downy, the upper part of the stem naked. The leaves are long, linear, and alternated. It grows on wet heaths in alpine situations. This species is the M. desparaspera of Lindley.

MOLYN, PIETER, [Tempora, P. C.]

MOLYNEUX (golnito-), C. S.

MONCREIFF, SIR HENRY, General and ecclesiastical leader in the church of Scotland, was born at Blackford, in Perthshire, on the 6th of February, 1750. His father Sir William Moncreiff, though a cedett of the family, succeeded to the title of his uncle, Sir Henry, and Sir John, and was made minister of Blackford, in 1744. Sir Henry was the sixth of his family that had belonged to the clerical profession. He studied at Glasgow and Edinburgh, and was ordained a minister on the 29th of August, 1771. Though he seems probably the only one of rank who ministered in the church of Scotland, he was as strongly imbued with the spirit of the Presbyterian policy as those, by far the most numerous class in that church, whom the advantages of rank and position had given a bias to the Deistical. His character and conduct in their particular case were matters of very much speculation.

He was for some time his father's successor as minister of Blackford, and in 1775 he was appointed to the charge of St. Cuthbert's, in Edinburgh, where he remained till his death on the 14th of June, 1807. He was frequently moderator of the General Assembly, and his name was con-
spicuous in nearly all the ecclesiastical discussions connected with the church of Scotland during his ministry in Edinburgh. He was the author of many pamphlets connected with these questions. In 1815 he published 'Discourses on the Evidence of the Jewish and Christian Revelations, with Notes and Observations' as much as respect for this Life and Writings of Dr. John Erskine.' [Erskine, JOHN, P. C. S.]

His Sermons, of which there had been some separate publica-
tions during his life, were collectively published after his death by his family and friends, who affixed a short mo-
mentary dedication of the author, by his son Lord Moncreiff.

MONEESES (from p5e5, sole, or alone), a genus of plants belonging to the natural order Ericaceae and the tribe Pyrole-

lens. It has a 4-toothed calyx; 6-lobed corolla; 10 inclined stamens; the anthers dehiscing at the base by two holes, the cells elongated and tubular; the stigma 4-toothed; the capsule 6-celled; the valves dehiscing from the apex, destitute of tomentum. There is but one species in this genus, M. grandif-

flora. It has a creeping root; large solitary terminal droop-
ing open white flowers, nearly an inch broad; very large stigmas. It is a native of Europe, Asia, and North America. It is a very useful plant, and is found in Great Britain, in the mountainous woods of Scotland. It may be cultivated in the same manner as the species of Pyrola. [WINTERGREEN, P. C. S.]

MONEY is the medium of exchange by which the value of commodities is estimated, and is at once the representative and equivalent of such value.

Barter is naturally the first form in which any commodity is exchanged. It is the most direct and obvious form of exchange article than he requires for his own use, exchanges a part of it for some other article which he desires to possess. But this simple form of exchange is adapted to a rude state of society, when commodities are not numerous and where their value has not been ascertained with precision. As soon as the relations of civilized life are established in a community, some medium of exchange becomes neces-
sary. Objects of every variety are sought and sold, the pro-
duction of which requires various amounts of labour; these at different times are relatively abundant or scarce; labour is bargained for as well as its products: and at length the ex-
changeable value of all things is determined, in a large, not in-
defined, and needs some common standard or measure by

which it may be expressed or known. It is not sufficient to know that a given quantity of corn will exchange for a given quantity of a commodity, but for their respective values to al-
ways be the same; but if a standard is established by which each can be measured, their relative value can always be as-
certained as well as their positive value, independently of each other.

As a measure of value only money is thus a most important auxiliary of commerce. One commodity from its nature must be measured by its weight, another by its length, a third by its cubic contents, others by their number. The diversity of their nature, therefore, makes it impossible to apply one description of measure to their several quantities; but the value of each may be measured by one standard common to all. Until such a standard has been agreed upon, the diffi-
culties of any extensive commerce are incalculable. One man may have nothing but corn to offer for other commodities, the owners of which may not have ascertained the quantity of corn which would be equivalent for their respective goods. To effect an exchange these parties would either have to guess what quantity of each kind of goods might justly be exchanged for one another, or would be guided by their own experience and accidental situations. In Europe the different kinds of commodity their experience would fail them, and they must guess more. But with money all becomes easier; each man adheres a price to his own commodities, and if barter should continue to be the form in which exchanges are ef-
fected, every bargain could be made with the utmost sim-

plicity: for commodities of every description would have a denomination of value affixed to them, common to all and un-
derstood by every individual in the community.

But however great may be the importance of money as a measure of value in facilitating the exchange of commodities, it is infinitely more important in another character. In order to exchange his goods it is not sufficient that a man should be able to measure their value, but he must also be able to find others who, having a different description of goods to offer as an equivalent, are willing to accept his goods in exchange, in such quantities as he wishes to dispose of. Not to enlarge upon the obvious difficulties of barter—suppose one man to have nothing but corn to sell, and another nothing but bricks: how can any exchange be effected unless each should happen to require the other's goods? But presuming that this is ac-
tually the case, it is probable that each will require as much of the other as will be an exact equivalent; or in other words, the commodities exchanged may not be proportioned to each other in any length of time, would therefore be extremely incon-
veni ent. In order to dispose of his corn, the producer might buy the bricks and dispose of them to others; but in that case, in addition to the business of growing corn he must beco-
me a seller of bricks. But human labour has a natural ten-
dency to a division of employments; and as society advances in wealth and in the arts of life, men confine themselves more and more to distinct occupations instead of practising many at the same time. [Division of Employment, P. C. S.]

With this tendency a system of simple barter is obviously in-
consistent; as by the one, a man is led to apply the whole of his labour to the production of one article, and in conse-
quence he has none to sell, but in the same way the other, for many. By the one he has only to produce and sell; by the other he must also buy what he does not want himself, and become a trader.

But all these difficulties are removed if some one commodity can be discovered which represents a certain amount of labour, and which all persons agree to accept as an equivalent for the products of their own industry. If such a com-
modity be found, it necessarily becomes the universal medium, whatever other commodities may be in circulation, and where their value has not been ascertained with precision.
barter gives place to commerce. But what must be the qualities of any thing which shall be productive of the products of their own labour? It is now no longer like a weight or measure, the mere instrument for assessing the value of commodities; but, to use the words of Locke, "it is the thing bargained for", and the condition of the bargainer. A bargain is complete when money has been paid for goods; it has no reference to the price of other goods, nor to any circumstance whatever. One party parts with his goods, the other parts with money; the former enjoys the value of the bargain, and the latter has the use of the money. But, though money as a medium of exchange thus differs from money as a mere standard of value yet in both characters it should possess, if it be possible, one quality above all others—an intrinsic value equal to its value under all circumstances. As a measure of value it is essential that it should always be the same, so that a yard should always be of the same length. And unless, as a medium of exchange, its value be always the same, all bargains are disturbed. He who gives his labour or his goods to another in exchange for a defensible denomination of value instead of for a full equivalent which he expects to receive, is as much defrauded as one who should bargain for a yard of cloth and receive short measure.

But however desirable may be the uniformity of money, complete uniformity of value is an impossibility. There is no absolute value. All likenesses of value do not correspond with absolute qualities, such as length, weight, and number, and may be invariable. But as value is a relative and not an absolute quality, it can have no invariable measure save in the mind. The value of all commodities is continually changing; some more and some less than others. Their real value depends upon the quantity of labour expended upon them; but temporary variations in their exchangeable value are caused by abundance or scarcity of any kind; by the relations which subsist between supply and demand. No commodity yet discovered is exempt from the laws which affect all others. If precisely the same quantity of labour were required for a long series of years to produce equal quantities of any commodity, its real value would remain unchanged; but if it were at the same time an object of demand amongst men, variations in the proportion between its supply and the demand for it would affect its exchangeable value. It follows therefore, that to be an invariable standard, money must always be produced by the same amount of labour, and in such quantities as shall constantly bear the same proportion to the demand for it.

But even if any description of money could be invented which possessed these extraordinary qualities, the value of all other articles would still be variable, and thus its representative value could not be disturbed. And in this case, a given denomination of money will represent a certain number of bushels of wheat; at another time, the same money, unchanged in real value or in demand, will represent a much greater quantity of wheat. Every merchant, a by-product of the skill and experience of mankind, facilitates production, and by saving labour reduces the real value of commodities. Their value is also liable to temporary depreciation from many causes, and to absolute or insufficiency. But if money maintain the same value, in relation to itself, notwithstanding the diminished value of other articles, its proportionate value is practically increasing. The consequences of a growing disproportion between the representative value of money and the value of commodities are these: Ist, a producer has to give a larger quantity of his goods than before for the same amount of money. Secondly, those who are entitled to payments in money, receive the value of a greater quantity of commodities than they would have received if the relative value of money and of commodities had not been disturbed. It follows from these circumstances, that, as a general rule, all creditors whose debts have been calculated in money derive advantage from any increase in its relative value to commodities; while debtors derive benefit from any circumstance which raises the value of commodities as compared with that of money, whether it be by increasing the value of the former, or by depreciating the value of the latter. To make these principles intelligible the following example may not be superfluous. A man finds a gold coin which he deposits in his bank for one year at a money rent; and that from any cause the value of agricultural produce is no longer represented by money during that year, he shall receive, at the end of the year, into his bank account the interest of the money he had lent to the public, but he loses the use of the money, which he had been continually increasing. In order to pay his rent, he must now sell a larger proportion of his produce, even though its total value is greater than before. On the other hand, his landlord receives the same money rent, but is able to purchase more commodities than before on account of the increased comparative value of money.

Thus men are insufficient to confine ourselves to the abstract qualities and uses of money, and to explain such general principles only as are introductory to the consideration of particular kinds of money, and of the modes of using and regulating them. In all ages of the world, and in nearly all countries, metals seem to have been used, as it were by common consent, to serve the purposes of money. It is true that other articles have also been used, such as beads, shells, silks, Sophisticated objects, highly civilized countries, and cowrie shells in the less civilized parts of Africa; but in all some portion of the currency has been and is composed of metals. We read of metals amongst the Jews, the Chinese, the Egyptians, the Persians, the Greeks, the Romans. In the earliest annals of commerce they are spoken of as objects of value and of exchange; and whenever commerce is carried on they are still used as money. But as they were introduced for this purpose in very remote times, it is not probable that they were selected because their value was supposed to be less variable than that of other commodities.

More than two thousand years ago, indeed, Aristotle saw the principal use of metallic money was that its value was less fluctuating than that of most other substances (Ethic. Nicom. v. 6). But however clearly this great philosopher may have observed the comparative inferiority of metallic money, he was not engaged in common barter, who considered their own convenience and security without reference to any general objects of public utility. They used gold and silver not as a standard of value, but as an article of exchange, which facilitated their barter. All metals are of great utility and have always been sought with eagerness for various purposes of use and ornament; but as prudent merchants, they have used metals as a standard of value, and as an article of exchange, which facilitated barter. Their comparative scarcity, the difficulty and labour of procuring them, their extraordinary beauty, their singular purity, their adaptability to purposes of art, of luxury, and display; their durability and compactness; must all have contributed to render them most suitable objects of exchange. They were easily conveyed from place to place; a small quantity would obtain large supplies of other articles; they were certain to find a market; none refuse to accept articles in payment which they could immediately transfer to others; and thus gold and silver naturally became articles of commerce, readily exchangeable for all other articles, before they were circulated as money, and were acknowledged as such by law and custom.

The transition of the precious metals from the condition of mere articles of exchange, amongst many others, to that of a recognised currency, was attended with the discovery of new principles. Money, articles at the moment when its value was estimated, was very natural. Merchants carrying their wares to a distant market would soon find it necessary to calculate the quantity of gold and silver which they could obtain, reduce to money, and spend for supplies, or to buy other commodities. They would not know what articles it would be prudent to buy until they reached the market and examined their quality and prices; but a little experience would enable them to predict the quantity of gold and silver which would be an equivalent for their own merchandise. Merchants from different parts of the world, meeting one another in the same markets, and finding the convenience of assessing the value of their goods in gold and silver, would begin to offer them for certain quantities of those metals, instead of engaging, more directly, in bartering one description of goods for another; and thus, by the ordinary course of trade, without any law or binding custom, the precious metals would become the measure of value and the medium of exchange.

But when gold and silver had attained this position in commerce, they were not the less objects of barter; nor were...
317

M O N

they distinguishable in character from any other articles of exchange. They were weighed, and being of the required fineness, a given weight was known as a denomination of value, but in the same manner only as the value of a bushel of wheat may be known. In the earliest ages gold and silver were readily fused and moulded and valued according to weight and fineness only. The same custom exists at the present day in China. There is no silver coinage, ‘but the smallest payments, if not made in the copper tokens, are effected by the exchange of such, which is at all times sustained by a little ivory balance on the principle of the steel-yard.’ (Davis’s China, c. 22.)

Notwithstanding the ease with which gold and silver are divided into small quantities, each of which is of the same intrinsic purity and value as the others, the trouble of weighing each piece, and the difficulty of assaying it, render these metals in bars, or other unassayed forms, extremely imperfect instruments of exchange, especially when they are used in small quantities. However accurately they may be weighed, it requires considerable skill and labour to assay them, which in small pieces would scarcely be repaid. Even in large quantities the difficulty of assaying their fineness, in countries which have made considerable advances in the arts, is greater than might be expected. The Chinese affect much accuracy in the art of assaying. The stamped ingots of silver in the possession of the Chinese are, for other commodities than natties, or sixty-eight parts in a hundred of pure silver, and two per cent. only of alloy; and strict regulations for maintaining this standard are rigidly enforced. Hence we should naturally infer that nothing but small fluctuations in the value of silver would be particularly directed to the most accurate assays. Yet at Canton an enormous trade in opium has for a long series of years been conducted entirely in silver, which has been found to contain no large mixture of copper, but that it bears a premium of five or six per cent. for exportation to England. (Davis’s China, § 22.)

If the Chinese have been unable to discover the presence of gold, which would be their interest to appropriately, how difficult must it be to detect alloys of base metals in gold or silver circulated amongst a people in the ordinary course of trade. To avoid this difficulty coinage was introduced, by which portions of gold, silver, copper, and other metals have been impressed with distinctive marks, denoting their character, and have become current under certain denominations, according to their respective weight, fineness, and value. These coins have always been issued by the government of each country as a guarantee of their genuineness; and the counterfeiting of them has been punished as a serious offence against the state.

In rich countries these three metals of gold, silver, and copper are very convenient substances for the manufacture of coins, on account of the differences in their relative value. Gold is the subject to continual variations and changes in its value, convenient for large payments, silver coins for smaller payments, and copper coins for those of the lowest value; while all the larger coins are multiples of the smaller. These several descriptions of coin are found to circulate suitably well: they are universally received as money within the country in which they circulate, and the principal part of all payments of moderate amount is made in them. But payments of large amounts cannot conveniently be made in coins of any metal; and in this and other countries paper money and various forms of credit have been used as substitutes. Of these we shall speak presently; but it will first be necessary to consider the suitableness of gold and silver coins as standards of value.

Coins made of these metals are not exempt from the laws which govern the prices of other commodities. They have accordingly undergone all the changes and fluctuations, and are at no time secure from variation. In the sixteenth century new mines of extraordinary richness were opened in America which were worked with such ease, and were so unusual a quantity of gold and silver, that the metals, though representatives of so much labour expended in their production, was lowered all over Europe to a third of their previous value. And thus a revolution, so to speak, was effected; from their present great extent they lost their standard fineness, in coins of a given denomination; 2; by raising their nominal value and ordaining that they shall pass current at a higher rate; and, 3, by debasing the metal. The first is an effect, the second a cause, but reducing the quantity of pure metal and increasing the quantity of alloy. In all these ways the coins of England were debased at different periods of our history; and to this present day the debasement of coins from the Conquest to the reign of Queen Elizabeth the total debasement of the silver coins have been estimated at 85 per cent. (Lord Liverpool, On Coins, p. 55.) By acting upon the principles of demerit of character thus produced, coins can be artificially raised; and the result of measures connected with the coinage of this country was, that in a period of 115
years, from the 1st James I. to the 1st George I., the value of gold coins, as compared with silver coins, was raised 89 per cent. (Ibid, p. 84.) No further examples are needed to prove the inconstancy of coins as a standard, when they form the sole currency of a country. Although there are the imperfections, the convenience of gold or silver coinage, as money, has led to the universal adoption of one or the other, or of both conjointly, as the standard of value. The objections to a double standard have already been noticed, but throughout a long period of the history of this country we find gold and silver prevailing equally as standards. There appears to have been no public coinage of gold at the royal mints prior to the 41st Henry III. (1236) for gold pieces at the value of less than 10s. were expressly declared not to be a legal tender, and never obtained a very general circulation. Silver was then the universal medium of exchange, and the people were accustomed to the use of gold as money: but as their commerce and riches increased gold naturally became more convenient for large payments. The results of this progress became apparent in the reign of Edward III., who established a general circulation of gold coins, which, though partially introduced nearly a hundred years before, by Henry III., had not been continued by his successors. From this time gold and silver coins circulated together, and were both legal tenders. To what an extent their value varied at different periods, has already been noticed; but they were equally recognised by law as authorised standards of value in all payments whatever, until the year 1774, when it was declared by statute (14 Geo. III. c. 33) that silver coins should be paid in payment of any sum exceeding 23d., except according to their value by weight, at the rate of 5s. 2d. an ounce. This was a temporary law, but was continued by several statutes until the year 1810, when the legal tender of silver coins was further restricted to payments not exceeding forty shillings (20 Geo. III. c. 65). And thus, as all large payments were made and calculated in gold coins, they became the sole standard of value, so far as coinage alone was the real medium of exchange.

The expediency of adopting gold as the standard instead of silver, has been a question of much doubt and controversy amongst the highest authorities upon monetary affairs. It was the opinion of Locke, of Harris, and Sir William Petty (all great authorities) that silver was the general money of account in England, and the measure of value in its commercial dealings with other countries. Its general adoption for such purposes was urged as a proof of its superiority as money over gold; and of this opinion are many thinkers of high authority, at the present day. On the other hand it has been argued that the metal of which the change is to be fabricated, should have reference to the wealth and commerce of the country for which it is intended; that copper or silver coins of the lowest denominations suffice for the commerce of the petty country; that advances in wealth its commercial transactions are more costly and require coins of corresponding value. As a matter of convenience this is undoubtedly true. Gold is the standard in countries where the standard of value is not in universal use; for in these countries the facilitating of effects large payments in the current coins of the two countries can admit of little doubt. Habit will familiarize the use of silver, and render a people insensible to its inconvenience; but it is certain that in England fifty sovereigns can be carried about in a man's waistcoat pocket, while in France the value of that sum in silver would weigh about 48 lbs. troy: so heavy and bulky indeed it would be, that a carriage would be required to convey it from one part of Paris to another.

But the convenience of coin for a certain class of payments is a question quite distinct from that of its fitness for a standard of value. It is not necessary to exclude gold from the coinage because it is not adopted as the standard; it may be circulated as freely as the people desire to use it, while, instead of being the legal standard, its value may be calculated in silver. If silver be the standard, a large gold coinage may circulate at the same time for the convenience of larger payments, just as silver circulates for small payments where gold is the standard. In either case, however, that metal which is chosen by the state, in order to govern all acts of commodities, shall be the metal which more nearly conforms to its standard, and is subsidiary to it. But even if the relative convenience of gold or silver as a standard were the sole question, it could not affect in the slightest degree the question of the value of either metal only. All payments are calculated as easily in the coins of one metal as of another, in whatever form they may be actually effected. But by far the greater number of bargains are made for articles of small value. It is in silver and copper that the consumption of all commodities is mainly paid for. The wages of the country are paid and expended in that form; and in this medium of large numbers of small articles of daily use are calculated. However the wholesale bargains of merchants may be conducted, the goods bought and sold by them are ultimately distributed to the consumers in very small quantities, the prices of which are estimated in silver and copper. The aggregate value of the small bargains must be equal to that of the large mercantile bargains which relate to the internal trade of the country, and in frequency and number, thousands of times as great. It is certain also that in the vast operations of commerce the bargains, in whatever medium they may be calculated, are very rarely paid for in any coin whatever, but are settled by various forms of credit; while all minor transactions—the bargains of daily life—can be adjusted by money payments only. It is for such purposes therefore that the metallic currency of a country is mainly needed; and it may be contended with much force that silver represents the value of commodities more universally than gold, and is consequently a fitter standard.

The fitness of a standard however cannot be determined solely by considerations of convenience; for we must chiefly regard its intrinsic qualities as a permanent measure of value. How shall uniformity of value be maintained as far as practicable in the money of a country? Is the main question to be determined by the medium of that coinage which is most easily adjusted to the wants of the people? If we think at all on the medium by which to make bargains? In what medium shall the whole property of the country be valued, from one year to another? By what standard shall the relative value of all things be compared? How shall fluctuations be restrained in the value of this standard itself? These are the questions to be answered.

In favour of gold as a standard it is argued that being less extensively used for plate and other manufactures, it is less an article of common use than silver, and is consequently more especially to the purposes of money. On the other hand, it is contended that gold is used in large quantities for jewellery, watches, and decorative purposes, and that being a comparatively unaccustomed and unaccustomed value affects its quantity and value to a greater extent than the use of plate affects the price of silver. And in this argument there is much weight, for it is estimated that the quantity of gold compared with the quantity of silver is 1 to 50; and their relative value is as 1 to 15. (See Bullion Report, 1810, Allen's Evidence.) Now it is evident that any variation in the commercial demand for gold must be more sensibly felt than a similar variation in the demand of the chief item of plate. But it is not sufficient to consider the demand for the precious metals as articles of consumption only; they are suddenly sought for in large quantities for other purposes, such as coins for the exportation of goods, or coins for the exportation of the commerce of a country; or there be a foreign war, its metals are in demand for the payment of the troops and for the purchase of foreign goods; and the com-
in the earth. No laws and no vigilance can restrain its export: as soon as it is wanted abroad, it disappears like water through a sieve. And this has been the case with England. Every other country in Europe has a silver standard; and whenever gold is wanted, its coinage supplies it. The exportation of which gold is annually limited; but it has been limited both in the past and in the present by the Bank of England. These are undoubtedly very strong objections to a gold standard, and in order to test them thoroughly it would be satisfactory to compare the actual prices of gold and silver, and estimate their relative values. But such comparisons are extremely delusive, for there is no common standard by which to compare the price of each metal. If silver be purchased with gold, how shall we determine in which there has been a Variation? Or if gold is silver, and one purchases on the same principle, there is a standard wanting, for the notes are made to conform to the value of gold, and not to the value of the silver. These elements of uncertainty make the attempt impossible. But, if we place ourselves upon them, the fluctuations in the price of silver bullion would appear to be very slightly greater than those of gold. (See Bank Charter Report, 1829; Bankers' Notes Report, 1841, No. 39, App. p. 39; Bankers' Notes Report, 1851, No. 39, App. p. 416.)

Results do not corroborate the objections to a gold standard; but it must be recollected that, independently of fluctuations in the prices of bullion, a diminution in the quantity of money circulating in a country raises the value of the remainder, and disturbs its relation to the prices of other commodities. It is in this form that the effects of an abstraction of gold must be felt rather than in the price of bullion; and though its influence on prices is very perceptible, the cause is not always perceptible. If a country had a circulation composed exclusively of gold, it might sometimes be deprived of all its money; if of gold and silver conjointly, it might sometimes be deprived of all its gold; but no country could be deprived of all or nearly all its silver by the operations of commerce. When paper money is added to gold and silver coins as part of the circulation, a country can always command a sufficient quantity of money, but the drain of its metals has an important influence upon the value of its circulating medium, and upon the operations of commerce; but of these matters more will be said hereafter.

The principle of the precious metals as standards of value have now been adverted to. Both of them are less liable to variation than any other known commodity which could be used for the purposes of money; but of the two, gold is the more important, upon the whole, the most suitable for a standard of value.

But whatever metal may be chiefly used as money, there is a disadvantage attending the circulation of coins which remains to be noticed. To maintain a large circulation of them is the most expensive mode of furnishing a people with a medium of exchange. In the first place the whole value of the metals of which they are composed is subtracted from the productive capital of the country in order to facilitate the exchange of other commodities. Unless this expense be absolutely necessary, it is an unwise extravagance. It is as if children should play at cards with gold counters instead of paper money. Such large impositions of the precious metals as standards of value have now been adverted to. Both of them are less liable to variation than any other known commodity which could be used for the purposes of money; but of the two, gold is the more important, upon the whole, the most suitable for a standard of value.

the country in which it is issued; but it differs from gold and silver, inasmuch as it cannot serve the purposes of an international currency. Gold and silver are current all over the world, and their value is everywhere understood; but paper-money is necessarily confined to the purposes of internal circulation.

2. Promissory notes issued by bankers or other persons unconnected with the state, not being a legal tender, may be refused in payment of any debt. They can only be circu-
late[1], therefore, with the entire concurrence of those who receive them. It is by means of banking accommodations, however, that they usually get first into circulation. A per-
son who wishes to borrow money does not particularly care in what form he obtains it, and be willingly accepts a note, if it be offered him instead of gold. He pro-
obly owes money to another, to whom he, in his turn, offers the note as payment. This third party will readily accept it, for he wishes to secure the payment of the debt, and if he distrust the value of the note, he may immediately call upon the party who issued it, for gold. When the credit and sol-
vency of a bank are well known in any neighbourhood, its notes pass from hand to hand without any distrust, but they rarely circulate beyond the adjacent district. Within its own district they are received as money, as readily as a state bank-note over the country; because they are sure to be returned for gold, just as a Bank of Eng-
land note would be returned from Russia. A bank of issue is also a bank of deposit, and the people amongst whom its notes are issued long enough to be sure that they will receive and credit for them—not as notes only, but as current money: and when they draw again upon their deposits, they may receive the amount in gold and silver or in state bank-
notes. It is consequently by a distinct medium between local gold and silver, and other descriptions of money is gradually lost sight of; they are readily convertible: they are universally circulate[d]; habit familiarizes the use of them; and at length, without the sanction of any law, they become money: there, and not the state, has coined them. Still any one may refuse to receive them, and the extent of their circulation depends on the credit of the issuer. Let a whisper be heard against his policy, and in a single day all his notes may be turned to him for immediate payment in the currency of the state.

The circumstances which occasion a large circulation of both these kinds of paper-money in a country, are the con-
venience of such a circulation, and the difficulty of obtaining a sufficient coinage for effecting the various purposes for which money is used. The demand for money is continually increasing in proportion to the increase of commodities in quantity and value: and in a rapidly improving country no coinage can keep pace with such an increase. When paper-
money is issued it does not supersede gold and silver, but is used in addition to them; not being the same as those of the coins; and if it be a properly regu-
lated currency, its value will also be precisely the same as that of the coins of a like denomination. A hundred pound note should purchase precisely the same quantity of goods as a hundred sovereigns. But how is this equality of value to be main-
tained between two descriptions of money differing so materially in character? Gold and silver, as already explained, have a known value as articles of commerce, and their real value depends upon the quantity of labour required for their production. If this continue unchanged for many years, their exchangeable value may still be liable to fluctuation by reason of varying proportions between supply and demand. The supply of them may be the same with an increased demand; or the demand may remain the same, and the supply be either increased or diminished. But paper has scarcely any real value when used as money; the labour expended upon it compared with its denomination value is merely nominal; and its value, supposing its credit to be good, must therefore depend entirely upon the proportion which the quantity issued bears to the requirements of commerce. If less be issued than there is a demand for, its value will rise; if it be issued in excess, its value will be depreciated. So strong is the operation of this principle, that promissory notes, which are a legal or national pressure, can be raised upon a premium of gold until they were issued in excess, and fell to a discount. It is evident, therefore, that the value of paper-money is independent of convertibility. If convertible, but issued in excess, its value will be depreciated; if inconvertible, but limited in amount, its value will be sustained. And further, if government paper and local notes be concurrently in circulation, and if the latter be in excess, the value of both will be depreciated, because the aggregate quantity of paper-
money will be increased beyond the demand for it.

The mode of regulating the issue of paper-money so as to sustain its value and to prevent it from fluctuating, is one of those difficult problems which have perplexed theorists and statesmen, and still remains to be completely elucidated by experience; but the principles upon which any sound system of paper-money must be founded are now agreed upon by the best authorities.

Let it be supposed that no paper-money is in circulation but government paper, paper-money must be converted into specie, and that it is the desire of government to maintain them at the same value as the gold and silver coinage. By what principle could the issue be regulated so as to effect this object? Gold and silver maintain a reasonable steadiness of price, as they are pos-
sessed of a real value, and being in demand over the world, are distributed in quantities proportioned to the wants of each country. Without any standard price being fixed by the state, their value will, therefore, be self-regulated; but paper-money is not an element of stability in itself, and unless its issue be adjusted with the utmost nicety, its value will constantly fluctuate. The object to be secured is an equality of value between all descriptions of paper-money, which is a necessary condition of an element of stability which is wanting in the latter, it is clear that paper-money must be made, in some manner, to conform to the value of the precious metals. Now this can be done either, by letting it pass directly into gold or silver, whenever its holders demand such a con-
version. To regulate the issues of inconverible paper is like filling a vessel with water in the dark, and without a measure: it is by the overplus that they are known to be full; while a convertible paper, under proper regulation, adjusts itself to the standard of the precious metals.

If convertibility be desirable when there is no other paper in circulation, paper-money issues may be avoided, and less

uncompensable when promissory notes are permitted to be issued by other parties; for, in that case, it is necessary to guard against an excessive issue of both descriptions of paper; and when government paper is convertible, other issues of paper will in some degree conform to its standard, as it, in its turn, conforms to that of the precious metals.

The manner in which convertibility restrains the over-issue of notes may be thus explained. If too much money be in circulation, its value is depressed, and the prices of commodities relatively raised. It thus becomes more profitable to export money than commodities in payment of the price of foreign imports. A diminished proportion of notes in the state, and a larger proportion in foreign countries, will raise the price of gold and silver, and whenever this occurs, the exchanges are said to be unfavourable. If a state bank issuing notes be re-
quired to give gold or silver in exchange for them, it must be willing to do so, and will do so as a constant proceeding. If it be the sole or chief bank of issue, it will be the prin-
cipal depository of bullion in the country; and thus any drain caused by unfavourable exchanges will be first and chiefly felt by it. Persons wishing to export bullion will demand it of the bank in exchange for notes. In this way the bank is apprised of the state of the foreign exchanges, and learns that money is too abundant; while it has the power of immediately curtailing its circulation by means of this very demand for bullion. It has merely to lock up those notes which it has received back in exchange for bullion, and every exportation of its bullion effects a proportionate contraction of the cur-
rency and restores the exchanges to a healthy state, by ad-
justing the quantity of money to the requirements of ex-
commerce. This is a simple mode of regulating the circulation of a country, and if all the paper-money were issued by one body only, it could not fail to be successful. So far as the principle has been tested in England it has been successful; but its operation has been interfered with by the competing issues of many independent banks, and by the admixture of notes not regulated by law. Both these causes of disturbance have been partially provided against by the recent Bank Charter Act (7 & 8 Vict. s. 32), and the experience of a few years will show if there be any imperfection in it. The subject of the paper-money of the country must be regulated by the foreign exchanges.

Any further reference to the particular laws and practice
by which the circulation of this country is regulated, in connection with a complicated system of banking, will be unnecessary for the explanation of principles, and these matters have already been sufficiently treated of. In the first place, we cannot quit the subject of convertibility without advertinge to a point of great importance. In order to regulate the issues of paper with reference to the exchanges, it is by no means necessary that there be a promissory note or claim, but a bill of exchange in the hands of the issuing body in exchange for its own notes. Uncoined bullion will serve the purpose equally well, and would occasion a considerable economy in the coinage. It would be much too expensive, and would lead to over-issue, to give bullion in exchange for its notes, at the standard price, whenever a certain amount should be demanded. There can be no object in giving facilities to every person who possesses a certain sum for the purpose of purchasing coin, unless caused by such facilities, in times of panic; while, on the other hand, no impediment would be offered to the great operations of commerce by raising the minimum quality of bullion to be demanded. By this arrangement whenever notes fell below the value of bullion, they would be brought in exchange for it, until the prices of both were again equalized; and if, by any undue limitation of issue, the value of notes should be raised above that of bullion, the bank should be obliged to give its notes in exchange for bullion. In this manner the circulation would be enlarged and the equilibrium between gold and paper restored. This excellent system was proposed by Thomas Working, and was entitled ‘Proposals for an Economical and Safe Currency,’ and was carried into effect, for a short period, on the resumption of cash payments, in 1819, but was succeeded by the present plan of convertibility of gold coin, which is more costly and less secure in its operations.

In regard to the issue of paper-money there are two antagonistic theories which must be noticed, although it will be impossible to enter fully into the arguments by which each is supported. By one it is proposed that all paper-money should, like gold and silver, be coined by the state alone, in order that its issue may be properly regulated and its convertibility secured. By the other it is maintained that the issue of paper-money should be open to all persons without restriction, like the drawing of bills of exchange, except in so far as securities may be necessary for the solvency of the issuers. In this country neither of these principles has been adopted singly, but the circulation has been founded upon the union of both. It has however been the policy of the government gradually to contract the issues of private banks, and to replace them by the notes of the Bank of England, which, for the purposes of issue, now stands in the position of the government itself.

In considering the relative merits of a system of government issues and of free competition amongst issuing bodies, there are three main questions to be considered: 1st, the profits arising from the issue of notes; 2ndly, the solvency of the issuers; and 3rdly, the value of paper-money as a medium of exchange and as a substitute for specie. The 1st question was solely considered, it would be difficult to oppose the claims of those who insist upon the right of free issue.

The profits arising from issues of paper-money may be regarded as one of the many forms in which profits are realized by trade. It is true that the right of issuing money has ordinarily been claimed as a royal prerogative, and that promissory notes might be included in that category. If such a claim had been made on the first introduction of paper-money, it could undoubtedly have been supported by the analogy which paper-money bears to a coinage; and if the law had been accompanied by the usual sinking clause, a benevolent legislature would have created, instead of a profitable branch of banking. But no such claim was advanced: the issue of notes has always been distinct from the coinage of money; and the state is now no more responsible for the solvency of its representatives, than for the solvency of those who act upon its behalf. But there is an essential difference between a promissory note and a bill of exchange. The one is money and discharges a debt; the other leaves a debt outstanding until the bill becomes due and is paid. Again, a note passes from hand to hand upon the sole credit of the issuer; a bill of exchange must pass through the agency of the acceptor, but also upon the credit and responsibility of each indorser. A bill is circulated amongst merchants precisely as credit is given to persons of known solvency; but a promissory note may be the bearer of the credit of the person issuing it, if received at all, is received as money. It is obviously just, therefore, that when the state permits so important a privilege to be exercised as that of the issue of money, it should at the same time provide for its limitation. The interest of individuals cannot be enforced without interfering, in some measure, with an unrestricted freedom of issue, but they are essential to the public safety, and they should on no account be neglected.

The solvency of the issuers of paper-money is a point which those parties only who may happen to hold the notes of a particular bank: it does not affect the whole country. If a bank fails, its creditors suffer like the creditors of any other bankrupt firm; but the general business of the country is not disturbed by its failure. On the other hand, however, the regulation of its issues had an influence upon the entire trade of the country. However effectual may be the securities against the insolvency of private banks—however complete the protection of the individual holders of their notes—the public interests are still in need of protection against the consequences of an ill-regulated currency. The securities against insolvency and the securities of the bank against the public are two different things. The former may be complete; the latter may, at the same time, be inoperative. The mode of sustaining the value of paper-money out of paper is precisely identical with that of specie. The paper-money is only an imitated silver coin, and it is said to be imitated. It is only by means of convertibility and by a reference to the foreign exchanges, that the issues of paper can be adjusted to the wants of the country; and this principle is incompatible with an unrestricted issue of paper by private banks.

If no control be exercised by government or by some central body over the issues of private banks, notes will be circulated, not according to any fixed principles or with reference to the exchanges, but to promote the business of banking. If too many should be in circulation, the action of the foreign exchanges cannot be brought to bear upon many independent banks with sufficient force and distinctness, and the convertibility of all the paper-money in the country is consequently endangered. This is the danger which is sought to be averted by restrictions upon the issues of private banks, and by the gradual substitution of the notes of one issuing body for those of many. No interference with the business of banking would be justifiable, except for the protection of the public interests; but the evils arising from the suspension of specie payments would be greater than the benefit to be derived from the exchanges, and for this reason, it is necessary to avert it. It renders all commercial transactions, it injures public credit, disturbs prices, and suddenly withdraws the standard of value by which all existing obligations and all transactions are judged. With a freedom of issue in one body only, a limitation of its issues, as already noticed, may sustain their value; but when many independent bodies are issuing notes, during a period of insolvency, there is no principle at work to regulate or to limit their issues, and it is almost certain that their notes will not only be greatly depreciated, but also will be liable to constant fluctuations of value.

There are some political reasons who have sacrificed every commercial transaction to an ill-regulated currency; while others deny its influence upon prices and upon the general arrangements of commerce. The opinions of both these parties are probably extreme, for with reference to the exchanges, and the general business of the country, no principle more certainly depends upon a healthy and well-regulated condition of the medium in which they exist. A well-managed currency cannot prevent the occurrence of periods of excitement and over-trade; but it will mitigate the effects of a great commercial pressure and distress; but it may tend very powerfully to diminish the frequency of their return, to restrain the suddenness of their outbreak, and to limit the extent of their mischief.

Remarks on the Management of the Circulation, 1840.
As yet such promissory notes only have been spoken of as are payable on demand: but a few remarks may be added concerning promissory notes and bills of exchange payable at some period more or less distant. These are regarded by some as money, and are said to form a part of the general circulation; but the essential distinction between them and paper-money has been more than once noticed above. They do not discharge obligations, but are merely written engagements to pay a sum at a future period. They are in practice the many forms of credit, and as such are used as substitutes for money; but they cannot be considered a part of the national currency. When transferred from one hand to another they become money, but as the offer of a debt to be paid the payment is guaranteed by each endorser in succession. It is true that they are among the most efficient agents for economising the use of money, and that they leave the circulating medium more free for other purposes, in which payments are made in notes or specie. If this were not the case, the circulation of notes must be almost indefinitely increased in order to meet the various demand of commerce; but this economy in the use of money makes a comparatively small circulation sufficient. It is this circulation, however, of which the relative scarcity or abundance affects the prices of commodities and the foreign exchanges. The final settlement of a bill of exchange must be adjusted to the current money of the country. If money be dear, the acceptor exchanges more goods for it in order to meet the bill when it becomes due; if money be relatively cheap, he makes a better bargain; but the exchange itself is the same, and all goods which had been originally purchased with it. Every bill of exchange when first drawn and accepted, and subsequently endorsed, represents, at each transfer, a distinct commodity, which bill is in circulation. The number and amount of bills of exchange in circulation cannot therefore be added to the currency in order to compare the aggregate circulation with the aggregate amount of commodities; for these commodities which are exchanged for means of bills may be set off against the value of other commodities represented by the bills, while the notes and specie taken together have a value in the aggregate of other commodities which will be added to the balance of the bank in an inquiring after the final settlement of bills of exchange. It is undeniable that bills of exchange perform many of the functions of money, and they are regarded as a part of the circulation by some high authorities in monetary matters; but it appears to us that the balance of reason and of authority inclines to the other side and assigns to bills of exchange a distinct place as substitutes for currency instead of including them as part of the currency itself. (See the Evidence upon this point before the Committee on Banks of Issue, 1840.)

A similar question arises in reference to the monetary character of the banking deposits, as they currency or not? The transfer of deposits pays debts and purchases commodities; it performs the functions of money, and so far would seem to be a part of the currency and to have an influence upon the foreign exchanges. But it is not a fact that the bill or deposit cannot be considered that the whole of the deposits are currency, for a large portion of them is invested by the bankers; and if every depositor were to call for his deposit at once, they could not be paid. Nor can the uninvested portion be properly called money; it is a form of credit which, like bills of exchange, economises the use of money and is a substitute for it, but is not the thing itself. It bears so close a resemblance to currency that to assign to it a distinct character is a matter of some difficulty; but still we are disposed to class all portions of banking deposits which are not actually held by the bankers in notes and specie, in the same category with bills of exchange and deposits, and transfer them to the list of the modes of facilitating the exchange of commodities by a refined species of barter, without the intervention of any circulating medium. Each transaction is valued in the current medium of exchange, and final settlement is made in the medium of exchange, and neither bank nor personal account is regarded as the money, but the estimated value of the transaction itself cannot be reckoned as a part of the circulation, for it were, then, commodities themselves would be money.

In the latter part we would select a good illustration of the functions of all forms of credits as substitutes for money. Suppose a merchant, A, to have indigo to the value of 100l., and that he wishes to purchase cotton of the same value, we assume that he will go directly to the merchant, B, to whom he sells the indigo. The transfer is made at once between them: the transaction is complete without the passing of a shilling, for the indigo performs the functions of money. But can the in-

MONKSHOOD. (Ac'antum, F. C. S.)
MONROEY, JEAN BAPTISTE, a very celebrated fruit and flower painter, was born at Lille, in 1635. He was educated as a historical painter at Antwerp, but he afterwards became the pupil of Peter Paul Rubens, with whom he remained ten years, when he was noticed and employed by Le Brun, and in 1655 was elected a member of the French Academy of Painting. He was employed by Le Brun in the decoration of the palace of the Duke of Montague, and was allowed to remain in Paris with many of his flowers and other similar pieces. It was owing to the beauty of these works that he was invited, about 1690, to London by the Duke of Montague, then English ambassador at Paris, to decorate Montague House (the late British Museum) in a similar manner; and the few and beautiful flower decorations of this palace, which is now pulled down, must still be fresh in the recollections of many. He painted in many other nobleman's houses in London and at other places; at Burlington House, at Lord Carlisle's, at Hampton Court, and at the Duke of St. Albans' at Windsor. One of his most remarkable works is a looking-glass painted in Kensington Palace for Queen Mary, who took such delight in seeing him paint that she spent nearly all the time that he was at work in watching him. There are fourteen flower-pieces by Monroyer, or Baptiste as he is now commonly called in England, in the apartment named George II.'s private chamber, at Hampton Court; they are however dirty and badly hung. Monroyer was commonly styled 'the flower-painter' in England in his own lifetime. He paid a fine of £500 to the Duke of St. Albans, but his permanent abode was in London, where he died in 1699, and was buried in St. James's. The French offended him by allowing his son-in-law, who was a painter and living at Paris, to call himself Jean Baptiste Monroyer. Monroyer's style, though not by far so minute or highly finished as that of Van Huysum, is infinitely more free and more brilliant, equal and true and effective. His selection of flowers, animals, birds, and shells, and the shade and touch, are all equally excellent and faultless: his works in their perfect condition must have rivalled nature herself. The brilliancy of his colouring is extraordinary. He was particularly fond of stamens, petals, and small objects, and a few white flowers together in a marble vase, and there are several etchings of such groups by his own hand: the vases are placed on pedestals or tables. His best works are in this country. The prints after his works amount to about 80, and make a good folio volume: his own etchings are marked J. Baptiste, sculp., whence probably his now common name of Baptiste. His son Antoine Monroyer, likewise a good flower-painter, was called the younger Baptiste in England. There is a portrait of Monroyer engraved by White from a picture by Sir Godfrey Kneller.

Essay towards an English School, 1706; D'Argenville; Walpole; Huber.

MONOTROPA (from μόνος, one, and ῥόδος, a turn), a genus of plants belonging to the natural order Ericaceae and the tribe Monotropae. It has a 4-6 parted calyx, a corolla of 10 petals, no stamens, and an ovary which is the only part of the flower left visible after the petals are fallen. The 10 stamens with kidney-shaped 1-celled 2-valved anthers; a pistil; a capsule; the 5-celled, 5-valved, many-seeded. The species of this genus are singular-looking plants, found growing at the roots of trees, and destitute of the green and bright colours which characterise the other forms of vegetation.

St. Hypopitys, Yellow Bird's-Nest, has the flowers in a drooping cluster, lateral ones with 8 stamens, the terminal ones with 10 stamens, the fruit erect, the bracts and flowers glabrous externally. The stem of this plant attains a height of 8 or 10 inches, is succulent, simple, clothed with ovate scales, terminating in a short cluster, dingy yellow, at length turning nearly black. The flowers with large scaly bracts. It is a native of Great Britain. This, with the other species of Monotropae, being constantly found at the roots of trees, was supposed to be parasitical upon them; recent researches have, however, led to the conclusion that in the case of this species such an opinion is erroneous. Mr. Rylands, in a paper published in the 'Phytophylac', page 25, has given the result of a very accurate investigation of the subject, and has proved that the fibres of the roots of Monotropae possess spongioles and take up their nutriment in the same way as other plants. Most specimens of Monotropae are found growing up, presenting a fleshy substance, which adheres to their fibres and the roots of the plant near which they grow, so closely, that they were supposed to be poritious of the roots of the Monotropae. On examining this fibrous substance with care, Mr. Rylands found that in all cases it consisted of a species of bozydyl fungus which had been developed upon the roots of the Monotropae, having no organic connection with these plants. The species of fungus varied in different specimens, and were found to belong to hitherto undescribed forms of Cryptogamia. There can be little doubt that the other species of Monotropae are of the same nature as Hypopitys, and that the microscopic spongioles in which the fibres of their roots are imbibed have referred the species here described, and two others, to a genus called Hypopitys. This includes the European species, whilst the old genus, Monotropa, embraces two American species, for Monotropa uniflora and M. uniflorus. The last species have not the musky semi-fragrant odour of those belonging to the genus Hypopitys.

(Don, Gardener's Dictionary; Phytogeog., vol. 1.; Babington, British Flora.)

MONTAGUE, GEORGE, was descended from an ancient family residing at Lakenham, in the central part of Wiltshire, where he had an estate. He was distinguished for his love of natural history, and was one of the early members of the Linnean Society of London. In 1802 he published an 'Ornithological Dictionary, or Alphabetical Synopsis of British Birds,' 2 vol. 8vo. This work exhibited much research as well as an extensive knowledge of the department of natural history to which it was devoted, and may be consulted with advantage at the present day by the ornithological student. In 1803 he produced his 'Tessae Britannicae; or Natural History of British Tissues,' with plates of five pieces, containing several plates and descriptions of new species. Besides these two great works he published several papers in the Transactions of the Linnean Society. Of these the following are the principal:

4. On the larger and lesser Species of Horse-shoe Bats, proving them to be distinct, with a Description of Vespertilio Barbastellae taken in the South of Devonshire. Vol. ix. 1805.
6. Of several New or Rare Animals, principally Marine, discovered on the South Coast of Devonshire. Vol. xi. 1811.
7. Of some New and Rare British Marine Shells and Animals.—Ib.

During the latter part of his life Mr. Montague lived at Knowle, near Kingsbridge, in Devonshire, where he died in 1814. (Biographical Dictionary of Living Authors; Watt's Bibliotheca Britannica.)

MONTALEMBERT, MARC-RENE, MARQUIS DE, a distinguished military engineer of the eighteenth century, was born July 16, 1714, at Angoulême. He was descended from an ancient and noble family; and, having received an education in which both literature and sciences were judiciously combined, he entered the army at eighteen years of age.

In the course of his first campaign (in 1733), he was present at the siege of Kehl, and in the following year he distinguished himself at the siege of Philipburg. He served afterwards with considerable reputation in Bohemia, when a French army under Marshal Broglie and Belleisle was in that country; and, on the retirement of the army from thence, he returned to Paris, where he devoted himself to the study of subjects which have relation to the military art. He was admitted a member of the Académie des Sciences in 1747; and he wrote several papers in the volumes published by that body. About the same time he established a foundry at Perigord for the purpose of casting heavy ordnance, which was then much wanted for the French Navy. During the Seven Years' War in 1757, Montaubert was attacked, as an agent for the French government, to the relief of the Swedish and Russian armies; and he appears to have been consulted by the allied generals respecting the arrangement of the plans for the different campaigns. In 1777 he
published a small work entitled 'Correspondence pendant la Guerre de 1757', which contains much interesting matter relating to that war. In 1779 he was appointed to construct a fort, and the application of several of his principles in the English fleet; and this fort, which was built entirely of wood, is said to have borne, without experiencing any damage, the shock occasioned by the simultaneous firing of all the artillery with equal force, so that it has been made in order to disprove the assertion of several engineers that the fort would fall in ruins by the fire of its own guns.

Montalembert published, in 1776, a small work in 1to, entitled 'Memoires de M. d'Enclos sur les Batiments militaires'; and in 1776, one under the title of 'Cheminée-Poêle.' He also published, in 1801, a pamphlet entitled 'Relation du Siège de Saint-Jean d'Arc.' But the work by which his name will always be connected with his profession, his memoirs, red in the fortification Perpendiculaire, ou l'Art Defensif surprie à l'Offensive, which was published at Paris in eleven quarto volumes (1776 to 1789).

In the first volume, having shown the defects of the bastioned fortifications which are constructed according to the principles of Vauban, he proposes to suppress the flanks of the bastions, continuing the faces of those works till they meet in the middle of each front of fortification, and, at the place of meeting, to have a casemated work like a small ravelling. The advantage to be gained by this project is, chiefly, a diminution of the expense of construction; and, after some other modifications of the existing fortifications, Montalembert dwells at length on that system which gives its name to the treatise. [Fortification, F. C.] The perpendicular fortification consists of four lines of rampart, the breakwater, the main range and the skirt, the side-skirt and re-entering parts, and three of these are defended by a powerful fire of artillery, which, being placed in casemates, is liable to be damaged by the enemy; while spacious terre-pleins, at the foot of each rampart, afford the troops of the garrison to engage the besiegers with forces superior to any which can be brought against them.

In the second volume, after giving an interesting account of the war in 1741, in which the importance of fortified positions is pointed out, he describes the construction of redoubts or small forts. In the third volume there is a project for the construction of a simple fortification, consisting of a casemated wall covered by a rampart on which are constructed casemated traverses: this is proposed as a good kind of defensive work for sea-ports; and it is said that some of the forts which defend Cherbourg were executed on that principle. The fourth volume contains an abridged history of the reign of Louis XIV., together with sundry projects relating to the formation of lines of intrenchments for the defence of the coasts. In the fifth volume is contained some observations on the fortifications of Cherbourg and on the isle of Aix. The ninth volume, which is particularly entitled 'L'Art Défensif supérieur à l'Offensive,' contains sundry projects for circular redoubts and for a casemated fortification, consisting of a casemated wall covered by a rampart on which are constructed casemated traverses: this is proposed as a good kind of defensive work for sea-ports; and it is said that some of the forts which defend Cherbourg were executed on that principle.

The leading principle on which the projects of this engineer are founded is, that a fortified post should contain an abundance of casemates for the security of troops and artillery: Montalembert considers that those alone will enable a small number of men to resist with success the attack of a numerous army, and that a few guns so protected are capable of destroying an enemy and putting an end to his science of war.

Montalembert married a lady who was distinguished as a performer on the French harp, and who wrote a novel entitled 'Elise Dusenmilli,' which was printed in London in 1798. It is said that Montalembert composed for the theatre some small pieces which had a certain success. An inscription to his memory is proved from the fact that his biographer, Lalande, had in his possession a number of his songs and tales in verse which are said to have been characterized by grace, elegance, and imagination.

In publishing his great work, and in making his experiments for the improvement of the military art, he seems to have incurred expenses which injured his fortune. He had given up to the government his foundations at Perigord, and his interest; a copious publication of works containing an equivalent were fruitless; he was even deprived of a pension which he enjoyed for the loss of an eye in the service of the country. About the year 1780 he came to London; but, after remaining some time, he, on account of the health of his wife in this country. It is said that, in order to save some of his property, he joined the revolutionary party; and it is painful to record that he entered so far into the prevailing spirit of the time as to be a member of the Committee of Public Safety. After being, however, employed to an artist on a work with which he had long been occupied—the construction of a considerable number of models relating to fortifications and artillery, and the valuable collection, when completed, he presented, in the Committee of Public Safety. At the same time, with other eminent engineers, he was constantly consulted by Carnot on subjects relating to the military affairs of the republic. He died of a dropy, March 29, 1809, being then eighty-six years of age.

(Éloges de Montalembert, by Delia de Sales; Biographie Universelle.)

MONTEN, DIETRICH, an eminent German battle painter, was born at Düsseldorf in 1799. He showed from his earliest youth a great love for accounts of wars and battles; and Honor, Tasso, and Ariosto were his favourite authors, and he used to read them while engaged in his profession. It is said that in order that he might have some practical knowledge in military matters he enlisted into the Prussian army as a volunteer in 1816, and served accordingly for twelve months. At the expiration of term of military service he entered the Academy of Arts of Düsseldorf, and after studying two years in that institution he removed to Munich, in order to benefit himself by the study of the works of Peter Iesos, who almost rivals Horace Vernet as a battle painter, and is still resident in Munich.

Monten was not long in attracting the attention of Cornelius, then the Caposucchi of the painters of Munich, and the notice of the present king of Bavaria, Ludwig I. He was intrusted by Cornelius, in 1827, with the execution of three of the frescoes of the arcade of the Hofgarten—the storming of a Turkish entrenched by the Bavarians at Belgrade in 1717, under the elector Carl Albrecht and his brother Ferdinand; the battle of Arcis sur Aube, in which the Bavarians under Wrede were engaged; and the granting of the Bavarian command to the Austrian general, Archduke Charles, in the battle of Sarnbruck, 1816, for the Hall of Victory (Sieges-Saal) in the state apartments of the new palace; and for the same patron of the arts, the departure of the Poles from their fatherland in 1831. These were followed, in 1830, in honor of the death of Gustavus Adolphus in the battle of Lützen, now in the King of Hanover's collection; in 1838, by George I. in the battle of Neerwinden; and in 1839, by the great camp in 1839 at Augsburg, for the Emperor Nicholas, at which that emperor was present. He painted besides these principal works many smaller pieces, which arc all conspicuous for extraordinary spirit in the incidents and in the execution, and display much fine drawing in colour and composition, though in many parts too sketchy and undefined; he wanted the necessary patience for elaborate modelling and uniform finish. But when the exact degree of this technical excellence is missed, its abstract form and absolute effect as a whole, and the general works have a very agreeable effect: their greatest defect is an occasional extravagance of action. His horses are always very spirited. He died after a short but severe illness, in December, 1844, in the prime of life, being in his forty-fifth year only, universally regretted by all who knew him. Several of his works have been lithographed by Bodmer, Hanßtingel, and others.

(Kunstblatt, 1836-1844; Von Hornay, Geschichtliche Fresken in den Arkaden des Hofgartens zu München.)

MONTGOMERY, ALEXANDER, an old Scottish poet, was a younger son of a good family in Ayrshire. The Banter Myntsrcr, written in 1698, contains some of his
MONTIA, a genus of plants named in honour of Dr. Joseph Monti, professor of botany and prefect of the medical garden at Bologna. He paid much attention to the scientific arrangement of the Gramineae and Cyperaceae. He published also a catalogue of the plants in the botanic garden at Bologna, in which he described several new species. The following are the principal works which he published:—1. 'Catalogue of the plants in and belonging to the garden of San Domenico,' Bononiæ, 1719, 4to. 2. 'Indicies Horti Bononiensis ad Utum Demonstrantium quæ in Horto Bononiæ quodam tempore hactenus.' Bononiæ, 1724, 4to.

MONTORSOLI, FRA GIOVANNI ANGELO, a celebrated Italian sculptor, was born in 1507, or about the beginning of the sixteenth century, at Montorsoli near Florence, on the road to Bologna, a villa belonging to his father Michele Angelo da Poggibonsi. He was first instructed by Andrea da Fiesole, with whom he lived three years. After the death of his father he found employment at Rome, at Pergamum, and at Volterra, where he assisted in making the monument to Raffaello Maffei. He was next employed by Michelangelo in the church of San Lorenzo at Florence, and gained the admiration and lasting friendship of the great Florentine. In 1521, at an interval between the affairs of the church and those of the State, he was called to Rome by Clement VII. to restore several ancient monuments, much to the dissatisfaction of his brothers of the Nunciata; he had been recommended to the pope by Michelangelo. Montorsoli restored the Laocoön, to which he made the right arm, and he made the left arm of the Apollo, and executed other restorations. When these and a statue of the pope were finished, he returned to Florence with Michelangelo to complete the statues and other sculptures of the sacristy and library of San Lorenzo, of which his best is San Coimo. After the death of Clement, Montorsoli again joined Michelangelo at Rome and assisted him in the works of the monument of Julius II.; but while engaged on this work he was invited by Cardinal Turone, and advised by Michelangelo, to go to France, and with him to Paris, to Francis I., who commissioned him to make four great statues, but owing to difficulties with the treasurer and servants of the court in France's absence, Montorsoli left Paris and returned to Florence without executing his work. He was then employed by Pope Clement VIII., in good work, at the Basilica of Saint Mary of the Flower, and its neighbourhood, he went to Rome to Naples, and there constructed the tomb of Jacopo Sansavizzo. His next finished at Genoa the statue of Andrea Doria which was executed by his brother Domenico. He also worked in the church of San Matteo there with many works. Upon the completion of these works he returned to Michelangelo at Rome, but departed again soon afterwards, in 1547, for Messina, where he was employed to make a grand fountain for the place in front of the cathedral. The principal basin is thirty-four palms in diameter, and is ornamented on its twenty irregular sides with twenty bassi-relievi illustrating the various aspects of the natural world related to the water element; it has become one of the usual meeting places and other dealers' centres for jetting the water: the whole fountain is crowned by a figure of Orion with the arms of Messina engraved upon his breast. The successful completion of this great work induced the Messinese people to erect another fountain in the front of the Dogana (Custom-house) close to the sea. He designed also at Messina the church of San Lorenzo, and several tombs. Among other considerable works in architecture and in sculpture, towards 1557 by a decree of Pope Paul IV., all religious persons, or all who had taken holy orders and were living at large in the world without respect to their religious character, were ordered to return to their convents and resume their religious habits; and Montorsoli was accordingly obliged to leave many works unfinished, which he intrusted to his pupil Martino, and he returned to his convent at Florence. He was however shortly afterwards called to Bologna to construct there the high altar of the church of his own order dei Santi, which he completed with great magnificence in twenty-eight months. He returned again to Florence, and being invited to be a sequester for artists in the chapter-house of the convent of the Nunciata, with the requisite endowment for regular masses at appointed times, and gave the whole sepulchre, the iron gates, and over the door, the picture of St. Luke, or company of painters, &c., which upon the completion of the sepulchre, was at a solemn feast celebrated by forty-eight of the principal artists of Florence, re-established by the consent and authority of the Duke of Tuscany, in a firmer and permanent basis; and the society still subsists as the Academy of Florence, though since that time it has been considered enriched and endowed by successive Dukes of Tuscany. Montorsoli died at Massari, on the last day of August 1569, aged fifty-six.

(Massari, 'Vite de' Pittori, &c.')

MORCELLI, STEFANO ANTONIO, born at Chieri, near Brescia, in 1705; studied at Rome, entered the Order of the Jesuits, was sent to Ragusa, and afterwards returned to Rome, where he was made Professor of Rhetoric in the Roman College. After the suppression of the Order of the Jesuits in 1773, he became librarian to Cardinal Alessandro Albani, and then wrote his work 'De Stilo Inscriptionum Latinarum Libri III.,' Rome, 1781. In 1790 he was elected Prior of the Chapter of his native town, Chieri, where he amused himself in doing good to his townsmen, and for their sake he afterwards refused the see of Ragusa, which had been offered to him. He founded an institution for the gratuitous education of young girls; he gave in his life-time his own select library to the town, and was requested to supply the churches of the same town, and was very charitable towards the poor. He died at Chieri, in 1821. Besides his work on inscriptions already noticed, he wrote: 1. 'Inscriptiones Commentatorum Epigraphicorum,' Bologna, 1774; 2. 'Commentarii in Inscriptionium Novarum Basilicarum.' 3. 'A collection of Ecclesiastical Commentaries' published by a former inscriber of the same name. Morcelli translated the MSS. from Greek into Latin, adding his own comments, and rendering it a valuable work on church history. 4. 'Explanatio Ecclesiastica Sancti Gregorii.' This Gregory is one of the earliest bishops of Agrippinum. 5. 'Africa Christiana,' 3 vols., 4to., Brescia, 1816. This is another important work on church history, from A.D. 197 till A.D. 697. It may be styled the Paul of the Christian Churches in Northern Africa.

Morcelli's works on inscriptions have been collected and published together:—'Opera Epigraphica,' 5 vols., with plates, Padua, 1825-28, and Professor Schiavi has added to them a Latin Epigraphical Dictionary in Latin and Italian. Morcelli wrote also a book of epigrams, 'Elogia Literaria,' 12 vols.; and various dissertations on Roman antiquities.

(Morcelli, 'Storia della Letteratura Italiana.')

MORDVINIS, PIETRO, an Italian sculptor, worked at Rome in the reign of Sixtus V., and in 1590 went to Vienna, where he executed for the Emperor the monument of Euphorbus, who died in the battle of Belgrade.

MORELLI, Domenico, an Italian architect of considerable note among those of the last century, was born at Imola in 1732. He was the son of Domenico Morelli (an architect also), and succeeded his father in several works of merit at Imola. It was Morelli's good fortune to obtain powerful patronage at the very outset of his professional career,—first that of Gian-Carlo Pandi, bishop.
of Imola, for whom he made designs for rebuilding the cathedral of that city, and through him, that of his nephew Giovanni Antonio Braschi, who was elevated to the papal throne in 1774, with which Francis I., Pope the First, was extremely partial. 

It is true that Filippo Buonarroti, as well as Piacentini, were entitled to a personal regard for Morelli himself, almost immediately appointed him architect at Cesena (the pope's native town), and among various other commissions commonly connected with his designs for the city, the archdiocese of  

Yet as far as employment and number of works go, Morelli had no reason to complain,—rather to consider himself favoured beyond most of his contemporaries, as will appear from the enumeration of the chief structures illustrated by him, namely, the cathedral of Imola, the metropolitan church at Fermo, the duomo at Macerata, and the conventual church at Fossombrone, St. Petronio at Castel Bolognese, a church at Barbiano, that of the nuns of St. Chiara at Imola, and St. Maria in regola in the same city, and another church at Lugo, also some alterations in the metropolitan church at Ravenna. It happens, too, rather singularly, that Morelli was almost as much employed in theatrical as in ecclesiastical architecture. The buildings of this class erected by him are— the theatre of Imola (destroyed by fire a few years afterwards, but preserved in the volume of engravings of A. Piacentini, Florence, 1771), Fermo in Pesaro; also the cathedral of Ferrara, which is confidently claimed for him by some, although Foschini was likewise in some manner or other employed upon it. [Foschini, P. C. S.] Besides the above works, he was employed at Bologna (St. Petronio), at Modena, the Berito at Naples, and the Cappi at Bologna; the façade of the Ricciotto at Cesena, and the Hospital at Imola, the façade of the Palazzo Publico, and the Palazzo Vecchio. He would probably discover more of the unrivalled structures of this class if we could see the finished copies of some of the engravings printed during his lifetime. 

He died, after a severe paralytic stroke, in February, 1812. (Pasotti, in Tipaldi’s Dizionario.)

MORELLI, GIA COMO, one of the most distinguished librarians of modern times, was born at Venice on the 14th of April, 1748. He was the son of poor parents, who were unable to give him a liberal education. It was against their will that he resolved to enter the church, although in all other respects he always showed the greatest deference to their wishes. He afterwards supplied the deficiencies of his education by private study; and the knowledge which he thus acquired was more substantial and extensive than that of any of his Italian contemporaries, though it was not till late in life that he became acquainted with the Greek and French languages, which he had to acquire for the benefit of the library of the family of the Zaniani, and his unwearied perseverance attracted the attention of the librarian de Rabais, who soon became his adviser and faithful friend. After having received from this learned patron of the arts, to his education, he acquired knowledge led him to examine the other libraries of his native city to which he could gain access. His love of independence induced him to refuse several very advantageous offers that were made to him both by the church and by wealthy collectors of books at Venice, and he continued to live as a simple Abbé. He formed however an intimate friendship with the patrician Fasnetti, of whose rich collection of MSS. he published a catalogue, under the title of Biblioteca Manuscripta del Bali T. G. Fasnetti," Venice, 1771-80, 2 vols. 12mo. While this work was in course of publication he also wrote "Dissertazioni Storiche intorno alla Publica Libreria di Mess.T. Mansi, a Venezia, 1774," and solved a great many questions connected with the history of literature. He then prepared a similar work on the history of the library of the academy at Padua, whither he had accompanied his friend Fasnetti; but the materials which he collected for that purpose were unfortunately lost in the hands of Colle, the historiographer of that institution, through whose carelessness they were lost. In 1776 he published a catalogue of his MSS. of the Narni family; and somewhat later a catalogue of the MSS. of Italian works contained in the same library. These works alone would have sufficed to secure to Morelli an elevated position, as they gave a valuable knowledge of the library from its venerable ancient building to a new one, the splendour and convenience of which however conspired to render him some measure of the loss of the former building. In 1795 he published an enlarged catalogue and description of the library, with the purchase of Dion Cassius, which he published at Basso, together with new various readings of other books of the same historian. This little work was afterwards (in 1800) republished at Paris, under the title of "Antichi Eruditi," in which he exhibited his extensive knowledge and his critical acumen in the strongest light is his "Biblioteca Manuscripta Graeca et Latina," of which however only one volume was published at Rome, although he had collected materials for several more volumes. His last production was "Epistolae Septemvaria Eruditionis," Padua, 1819. Abbé Morelli is acknowledged by all who had occasion to visit the library of St. Mark during the time that he was at the head of it, to have been the most amiable, kind, and obliging person, and his vast learning was equalled only by his extra-ordinary modesty. After his death there appeared, "Operette osservazioni su Opuscoli di Antichi SCRITTORI," Venice, 1820, 3 vols. 8vo. 

(Bettio, Orazione recitata nelle soleone Esequie nella Chiesa Patriarciale di Venezia, Venice, 1819.)

MORGEN, RAPHAEL SANZIO, Cavalieri, one of the most celebrated engravers of recent times, was born at Florence, June 19, 1728, by his own account, according to the authority of Niccolo Palmarini, his pupil, who published a complete catalogue of his works. 

Morgen's grandfather was a lace-merchant of Montpellier, who married a woman of the same name, who was settled in Florence, where he had two sons, Filippo and Giovanni. They both followed the arts: Filippo, the elder, and the father of the subject of this notice, was an engraver. He settled early in Naples, and married a French lady, who degenerated, in modern times; but he acquired a still greater reputation as librarian of the library of St. Mark, an office which he received in 1778, and which he held until his death, which happened on the 6th of May, 1819. He devoted himself with the greatest zeal to the completion and arrangement of that famous library; but during the French rule in Italy he was dismissed, to be re-appointed in 1815, when the new papacy were treated with great personal regard for Morelli himself, almost immediately appointed him architect at Cesena (the pope's native town), and among various other commissions commonly connected with his designs for the city, the archdiocese of...
Philipp must have made a visit with his wife to Florence some time after his marriage, and before the birth of Raphael, as it is founded as an engraving in the second print. Of the second print there are eight different kinds of impressions:—etchings, in five degrees of progress, in which additional portions are finished; fifteen impressions in which all is finished, but the book in the handwriting of Andrea Doria, the degree of progress, with the inscription, 'Et transfiguratus est ante eos,' written with the needle; and, lastly, the commissionately finished proofs. This engraving is a work of great labour, of great skill, of a very extraordinary execution of the lines goes, yet it leaves much to be desired; it wants tone and aerial perspective, it is hard and metallic, red, all, as when, though the individual figures are beautified, but the whole, is cast-away from the catalogue. Dr. Nagler has reprinted the list entire in his Roman Lexicon.

MORHOF, DANIEL GEORGE, is well known as the author of a very useful work, entitled 'Of the History of the Gunpowder, &c.' After his father, extending to 78 closely printed quarto pages, is prefixed under the title of 'Prolegomena,' to the second volume of that work, by the editor, John Moller, rector of the grammar-school of Flensburg in Schleswig. From this copious dissertation it appears that Morhof was born at Wismar, in the duchy of Mecklenburg-Schwerin, on the 6th of February, 1699. His father was Joachim Morhof, notaary public, assistant-clerk to the town-council (Senator urban Lip; just in the City), who had been of humble parentage in the Mark of Brandenburg, and is described as distinguished both for his prosthesis and his learning; his mother was Agnes, daughter of Daniel Hintz, a respectable merchant. Young Morhof was taught his Latin rudiments at home by his father, who also made him early familiar with the Bible and with the elements of general history. Before he knew his alphabet he was fond of muscular exercises, and he was distinguished for his precocity and rapid progress. When he was in due time sent to the Athenaeum, or academy, of his native town, he distinguished himself not only in Latin and Greek, but in history and in the mathematical sciences, and in 1656, he received the degree of M.A. He was next assigned to the Paedagogium of Stettin; whence after two years he proceeded to the university of Rostock to study law. He continued however to give a great share of his time to elegant literature, and especially to poetry, composing verses both in Latin and German with great facility and much to the admiration of his friends. In 1660 he obtained the professorship of poetry in the university. In the beginning of the same year, before commencing his public prelections, he visited Holland and England, remaining for some time in this country that he might have the use of the Bodleian Library. He also addressed a petition to the king in behalf of the German printers and engravers. On his return to the Continent he was made doctor of laws by the University of Franeker, in Friesland, on the 26th of September, 1661. He greatly distinguished himself by the manner in which he defended the duties of his profession. In 1666 he was invited and induced to accept the appointment of Public Doctor of Eloquence and Poetry in the newly founded university of Kiel in Holstein. In the summer of 1670 he made another dramatic tour, this time to Syria, Egypt, and Italy, and stayed for a considerable time in London, where he enjoyed the society, among others, of Boyle, Isaac Vossius, and Oldenburg, the secretary of the Royal Society. On the 23rd of September, he fell sick, and died at Copenhagen, on the 26th Caspar a Degen, senator of Udine, of the plague. She died in 1687, after having brought him four sons; of whom the second,
George Marquard, and the fourth, Eric George, died young; the first, Caspar Daniel, and the third, Frederic, survived their father. In 1580 Morhof succeeded to the professorship of history; and in 1680 he was appointed librarian to the university. The latter charge to so devoted a reader was peculiarly gratifying. From the time of the loss of his wife, however, his health began to break down. In 1650 he was attacked by a serious illness, and it really seemed for a time as if the following year he would undertake an ill-advised journey to the mineral waters of Pyrmont, from which he never returned: he only got back as far as Lübeck, and there breathed his last, on March 2, 1668, in the fifty-third year of his age. Morhof was a very voluminous author. The account of his writings, published and unpublished, fills nearly fifty pages of the memoir by his friend Möller. His first production consisted of two Latin poems, published together in 1527. This was followed by an academical dissertation entitled 'Dias tribus monibus et eorum Remedia Juridica,' in 1569; and afterwards, among other works, by an octavo volume entitled 'Epigrammatum et Jocorum Centuria Prima,' in 1569; 'Dias tribus Philologicae de Novo Anno ejusque Ritibus,' in 1568; a curious dissertation of the miraculous powers claimed by the kings of England and France in the cure of the king's evil, under the title of 'Principis Medicus,' in 1565; a volume of 'Miscellanea Poetica,' in 1566; another entitled 'Vencrum, sive Epitaphianlunmar, Liber,' in 1567; another entitled 'Fune raria,' in 1568; a volume of verse at various times; a translation into Latin of several of Boyle's tracts, in 1671; 'Disputatio de Sole Ignea Academicca,' in 1672; in 1673 'Epitaphi de Transmutatione Metal. legum,' with a Latin dedication to Senex, evidently that of the philosopher's stone; in 1692, an 8vo volume, in German, on the history of the German language and poetry ('Unterricht von der Deutschen Sprache und Poesie, &c.,') with a collection of his own German verses ('Sussnere Gedichte'); in 1684, 'Liber de Pataviniat Liviana'; in 1686, 'Oitiron Divinorum, seu Carmina Sacrorum, Liber,' and the first and second books of his 'Polyhistor,' in 1688. After his death appeared, among other works, in 1694, 'De Cultu Morhoffi CVIII, Quaestiones Chymicae, ex varia Autoribus Chymicis collectae; in 1697, 'Morfobii Opera Poetica Latina omnia,' in 1698, 'Morfobii Orationes et Programmata;' in 1699, 'Morfobii Dissertationes Academicae et Epistolae.' For the works which he left in manuscript, mostly in an unfinished state, and which have never been printed, we must refer to the ample pages of his biographer. They are far too numerous to be noticed here. So great a quantity of literary production in so short a life sufficiently attests Morhof's diligence and facility. His judgment, however, appears to have been hardly in proportion to his acquirements; and even his imagination was quite as remarkable in extent as for its depth. Of all the masses of authorship to which his name is attached, his 'Polyhistor' is, we believe, the only portion that is still held in any esteem. The work is 'Polyhistor Literarum, Philosophiæ, et Practicarum.' Of the 'Polyhistor Literarum,' intended to form the first volume, Two Books, as already mentioned, were published by the author himself in 1688. They were brought out in 4to, at Lübeck. The First is entitled 'Bibliothecarius;' the Second, 'Methodicus.' As reprinted in the last edition of the work they make together 588 pages. A Third Book, entitled 'Papæ et Sacerdotum,' was printed from Morhof's manuscript at Lübeck in 1692, with a re-impression of the two preceding Books. It extends to 156 pages. The remainder of the first volume, consisting of Book iv., entitled 'Grammaticæ,' (306 pp.); Book v., entitled 'Criticæ,' (20 pp.); Book vi., entitled 'Poetica' (72 pp.), was compiled from notes of Morhof's lectures, by Moller and John Friekius, professor of theology at Ulm; they also added the 'Polyhistor Philosophica,' in Five Books; and the 'Polyhistor Practica,' in Seven Books; and published the completed work in two vols. 4to. in 1704. A new edition of the whole work was produced in two vols. 4to., by John Albert Fabrius, in 1751; as well as a 12mo. 4to. in 1754. All the editions have been published at Lübeck. With the ample indices which Fabrius has appended (though the plan of notation is rather complicated), and with the corrections and additions which he has received from an accurate learning, the 'Polyhistor' is still a useful survey of universal literature down to the middle of the last century. As in almost all such works, however, some subjects which happened to be favourites with the author or his editors, are treated at disproportionate length, while others of greater real importance are too summarily dismissed. MORO, ANTONIO, or Sir Anthony More, was born at Utrecht, in the year 1526, and was the pupil of Joan Schoorlac. He obtained, while still young, a great reputation at Rome, especially as a portrait painter, and when the Emperor Charles V. requested the Cardinal Granvelle to send a painter to Madrid to execute a portrait of the King, the cardinal selected More. He was introduced to the Emperor, at Madrid, in 1552, painted Philip's portrait there, and, at Lisbon, painted besides the Infanta Mary, King John IV., and Queen Catharine of Portugal; for which he received 600 ducats and a very valuable gold chain as a present. Van Mander says that his usual price for a portrait was 100 ducats, which at that time was a very large sum. After a short interval, in 1554, More was sent to paint another bride of Philip's, Queen Mary of England; for this picture he was also richly rewarded, says Van Mander, and had a salary of 100l. per annum allotted upon him, as painter to the King and Queen (Walpole says 100l. per quarter). More remained in England during the reign of Queen Mary, by whom he was probably knighted, and he painted several portraits of her and many of the English nobility of that time, some of which are at Hampton Court, and many others are still in the private collections of the descendants of the families. Some of his works, however, were never painted. More was much inferior to Holbein. After the death of Mary, in 1558, More rejoined Philip in Spain, and appears to have lived on such terms of familiarity with the king, that, upon an occasion of which there was a great amount of curiosity, he declared that he believed the king to have made his second marriage with his open hand on the shoulder, the painter ventured to return a blow with his mahlstick, but he soon repented of his familiarity, and was heartily glad to escape with temporary banishment. Philip, however, sent to recall him, and the king's messenger overtook More on his way, but the painter excused himself, not daring to trust himself again within Philip's power. Philip wrote to him in the Netherlands, but, through the Dutch Ambassadour, as a subject of Spain, gave him a salary of 150, and allowed him to paint in Madrid. Van Mander says that More had the service of the Duke of Alva, who sent for him from Utrecht, and he was appointed by the duke receiver-general of the revenues of West Flanders, an appointment, says Van Mander, which he declined, that he made a hundred of all his painting materials at Utrecht, and made presents to all his friends. Some suppose from this that he gave up painting; but so far from this, he was constantly painting, especially portraits of women, for the duke, at Brussels, whose high position enabled him to reward the painter with a public office for private services. The whole of More's family was also richly provided for, by Philip, or by the duke. More died at Antwerp, in 1581, aged fifty-six, while engaged on a picture of the Circumcision, for the church of Notre Dame there, and it was left unfinished. More painted chiefly portraits, which were, however, often bought by pieces by him, but they are painted in the prevailing dry style of that time in the Netherlands, and with its hard positive colouring. Yet he made a good copy for Philip, of Titian's Danae, which is now at Madrid. There is much confusion about the dates of More's birth and death, some placing his birth in 1512; the above, however, is the account in the second edition of Van Mander, where it is fully explained in a note. More's portrait is in the Florentine gallery of painters' portraits. (Van Mander, Hel Leem der Schilders, &c., 1674.) MORONI, GIAMBATTISTA, a celebrated Italian historical and landscape painter, was born about 1510, at Albino in the territory of Bergamo, and was the scholar of Moretto da Brescia, whom he did not equal in invention, but surpassed as a portrait painter. In this last branch he was inferior to Titian only in his time, and that great master had to be repeatedly recommended applicants to go to Moroni. The heads and draperies of his portraits are beautiful; the hands might be improved. In his historical pieces he belongs rather to another age. His later works are almost valueless. In 1786 the date of his death is not known, but his works range, according to Count Tassi, from 1557 to 1579. (Tassi, Vite de' Pittori Bergamaschi, &c.; Lanz, Storia Fittoriciana.) MORPETH, a municipal and parliamentary borough in the township and parish of Morpeth, in the western division of Morpeth ward, in the county of Northumberland; 302
miles from the General Post-office, London, by the former mail-coach road through Ware, Huntingdon, Grantham, Newark, Doncaster, York, Thirsk, Northallerton, Durham, and Newcastle-upon-Tyne; or 331 miles—namely, 307 miles by rail (regular stage, 13 hours and 15 minutes). There is a regular stage from London to Edinburgh. The parish of Morpeth comprehends an area of 7600 acres, and is partly in the east and west divisions of Castle ward, and partly in the north and south divisions of Morpeth ward. The population at the different enumerations in the present century was as follows:—1801, 5707; 1811, 4098; 1821, 4292; 1831, 4797; 1841, 4297. It is divided into six townships ;—Morpeth Town, (the latter having Catchburn and Stobhill united with it), in the east division of Castle ward; Newminster Abbey, Shilvington, Tranfield and Highchurch; and Twissel in the west division of the same ward; and Morpeth and Beller's-green in the west division of Morpeth ward. The boundaries of the municipal borough include about half of the area, and nearly all the population of Morpeth town, and a small part of the township of Newminster Abbey; the town is chiefly in the borough, but a portion of it is in the township of Beller's Green. The number of houses and persons in these two township-houses coincides with the number of houses and population of the town. The return in 1831 and 1841 were as follows:—

The diminution of the population, 483, or nearly 12 per cent., in ten years, and the circumstance that there were no houses building in 1841, show the decline which had taken place. The parliamentary borough was described by the Boundary Act, 1832, as consisting of the parish of Morpeth, excepting the townships of Shilvington and Twissel (population of the two 151 in 1831, 137 in 1841), and the adjacent parish of Bedlington, or Bedlingtonshire (population in 1831, 2120; in 1841, 3165), a detached portion of the county of Durham. The population of the parliamentary borough in 1831 was therefore 6766; and in 1841, 7255.

Morpeth town stands in a sort of peninsula formed by the windings of the river Wanebeck, which surrounds the town on the west, south, and east side, but is not navigable. The road from Newcastle enters the town from the south by an elegant trim bridge over the river, erected by the designs of Mr. Telford, and there is a suspension bridge on the west side. The streets are irregularly laid out, and, when the Municipal Corporations' Commissioners made their report in 1835, they observed that they were not generally improved, and were not in fact quite paved with pebbles, but in 1838 the pavement was taken up and the streets macadamised, to the great comfort of the townsmen and travellers. The town is supplied with water from a spring at Stob-hill. There are not many good houses in the town. The church is nearly half a mile from the town, on the south side of the river: it is in the style of the fourteenth century, and consists of a nave and chancel, and a western tower, engaged with the nave: few old churches are more destitute of objects of interest, architectural or antiquarian. In the spacious churchyard is an ancient octagonal cross, but little injured. In the town, close to the bridge which is a mile as the crow flies from the grammar-school, and part is still used as a chapel-of-ease for performance of divine service. In a suburb of the town, on the south side of the bridge, on the east side of the road, is a good and house of correction for the county, erected about twenty years since, at a cost of 70,000/. It is an octagonal building, entirely of stone, in a dry and elevated site. The average number of prisoners in the year 1842 was 25, and a total at any given time has been about 40. The principal part of the building is used for stock-pieces at almost every theatre where there is any regular European performances. Near the opposite side of the road, are the remains of Morpeth Castle, a rude and strong building, of which the gateway-house and the outer wall, now much shattered, are still standing; the area enclosed by them, 92 yards by 68, is occupied as a nursery-ground. The townhall, a building by Sir John Vanburgh, was used as a sessions-house until the erection of the present gaol. There are a Roman Catholic chapel; and meeting-houses for Presbyterians, Independents, Methodists, and Morpeth Baptist, and a quaker meeting-house. The antiquary, author of 'Britannia Romana,' was minister of the Presbyterian congregation from 1723 till his death in 1731, at the age of forty-six. The trade of Morpeth is chiefly that of much of the north of England and the north of Scotland; but there is a good weekly market on Tuesdays for live stock on Wednesday: the weekly sale of oxen is 100; of sheep and lambs, 300. There are a dispensary, a savings-bank, a subscription library, and a Mechanical and Technical Institute. The grammar-school was opened the first week in September, on a course on Cottong-wood, north of the town. The race-course is about a mile and a quarter in circuit.

Morpeth is a borough by prescription. Under the Municipal Corporations' Reform Act, it has 4 aldermen and 12 councillors, and is not to have a commission of the peace except on petition and grant. The borough first sent members to parliament in 1653. It returned two down to the time of the Reform Act, when it was reduced to one. By the Boundary Act its limits for parliamentary purposes were enlarged from the existing municipal boundary to the extent already described. The number of registered electors was in 1835-6, 554; in 1839-40, 583; in 1842-3, 428, namely 142 freemen and 286 ten-pound householders. Morpeth is a rolling-station for the northern division of the county of Northumberland.

The town of Morpeth is not noticed in history till the reign of John (a.d. 1199), who granted a charter for a fair and market; and in 1731, a fair was entered on the corporation by John A. J. Hodgson, 'for the fair and market, the horse-race, and the barons.' In the civil war of Charles I., Morpeth Castle was occupied by a body of the Scotch Covenanters, from whom it was taken in 1644 by the Marquis of Montrose. The late Dr. Morrison, the eminent Chinese scholar, was a native of Morpeth. The town gives the title of Viscount to the Earl of Carlisle, and by courtesy to his eldest son.

The living of Morpeth is a rectorcy, with the perpetual curacy of Uppington, and the vicarage of the archdeaconry of Lindisfarne, in the diocese of Durham: the annual value of the benefice is 111l., with a glebe-house.

There were in the borough in 1838 thirteen day-schools with 448 to 468 scholars, viz. 260 to 270 boys and 188 girls; giving less than one-eighth of the population under daily instruction. Of the day-schools one, with 43 boys, was a free grammar-school founded and endowed by Edward V.: two others were supported by the corporation. There were four Sunday-schools with 464 scholars, viz. 209 boys and 255 girls. Lending libraries are attached to two Sunday-schools; one (that of the Church school) is for the general use of the parish. A library of little value is attached to the grammar-school.

(Parliamentary Papers; Hodgson, History of Northumberland.)

MORTON, THOMAS, was born in 1764, in the county of Durham. His parents having died while he was young, his uncle, Mr. Maddison, a stockbroker in London, took him into his care. He was educated at the Soho Square Academy, celebrated for its theatrical performances of the pupils, several of whom became distinguished actors. He afterwards entered a student of Lincoln's Inn, but the fondness for theatrical amusements which he had contracted at school was not to be subdued; he became a constant play-goer, and directed his studies to the drama rather than the law. Having written a dramatic piece which was favourably received, he abandoned the legal profession without having been called to the bar.

Morton thenceforward devoted himself entirely to play-writing, and became one of the most successful of modern dramatists. So great was his reputation and the confidence of managers in him, that he was commissioned to write for the Old Covent Garden Theatre, and his comedy of 'Town and Country' was to be brought out in 1807. Mr. Harris, the lessee of Covent-Garden Theatre, gave him 1000/ for it before the play was to be produced. But, afterwards, taking on himself all risk of failure, out of fourteen or fifteen comedies, comic-operas, and farces, five or six still continue to be stock-pieces at almost every theatre where they are met with.
Morton was a respectable man, of regular and orderly habits. His conversation was sprightly, and abounded in anecdotes of cricket and other sporting matters. He was a conspicuous and meritorious attendant at the cricket-grounds, where he enjoyed his favourite exercise. He died March 28, 1838, in his seventy-fourth year, leaving a widow, three sons, and a daughter.

The portrait of Inchbald, on which he is seen playing only by reading him, his uniform and great success will probably matter of surprise; to those who are engaged in dramatic writing, it must be no less a matter for investigation. Morton has a happy gift of imitating the impression of a great man, deficient in the highest qualities of the art. He gives no true representations of character either in its broad and strong markings or in its nicer discriminations; he shows nothing of the real operation of motives, nothing of the genuine workings of feeling; his serious and his comic characters are alike artificial and exaggerated; they are strictly and peculiarly stage-characters, and anything resembling them in real life will rarely if ever be met with. But he has extraordinary dramatic tact: he foresees distinctly what may be effected in the performance, and the situations, as well as the characters are admirably contrived for displaying an actor's skill, abounding in episodes and transitions, and brimming with passion, overflows of excessive liveliness, or exhibitions of strange peculiarities, such indeed as have never been witnessed, but which, when well performed, are exceedingly amusing. Mr. Morton has not wit and elegance, but is never languid or heavy; and the very speeches which when read produce a smile of contempt or a feeling of incredulous disgust, afloat to Lewis, Munoden, Quick, Fawcett, and John Saunders, and W. Vernon, who was the painter by which they were enabled to exhibit the triumphs of the actor. (Gentleman's Magazine, 1838; Biographia Dramatica, by H. Reed and J. Jones; Inechilt's British Theatre.)

MOSES, GEORGE MICHAEL, R.A., gold-chaser and enameller, the first keeper of the Royal Academy of Arts in London, was born at Schaffhausen in Switzerland, in 1704. He came young to London, and was first employed as a chaser in gold and also of brass for the ornaments of cabinet-work, in which he obtained a great reputation. He was also an excellent medalist and a good painter in enamel, but he did not carry his works in this respect much beyond enamels for watchcases, in one of which he painted, for the king, George III., portraits of the Prince of Wales and the Bishop of Osnaburg. He was for some years kept by Sir Christopher Wren, who was an old friend of his, and who appointed him body-chaser for the Royal Academy of Arts. In 1768, he was elected for many years treasurer and manager of the private academy in St. Martin's Lane. He died in the beginning of 1783, and Sir Joshua Reynolds wrote an eulogium upon him, which is printed in Malone's Life of Sir Joshua. As a chaser in gold, says Sir Joshua, Mozer was the first in his profession; and he had a universal knowledge in all branches of painting and sculpture. 'He may truly be said,' he continues, 'in every sense to have been the father of the present race of Britons.' Hogarth, Rysbruck, Roullilac, Willis, Ellis, and Vanderbank, were Mozer's early companions, all of whom he outlived.

Mary Mozer decorated an entire room with flowers at Frogmore for Queen Charlotte, for which she received 300l.; the room was called Miss Mozer's room. After her marriage she practised only as an amateur; she died at an advanced age in 1819. When West was reinstated in the chair of president of the Royal Academy, he secured the appointment of Sir Joshua Reynolds, whose name is a synonym in art for the true artist, a man of great and far-reaching powers. Sir Joshua Reynolds was a man of great and far-reaching powers. Sir Joshua Reynolds was a man of great and far-reaching powers. Sir Joshua Reynolds was a man of great and far-reaching powers.
tions of the country are savannahs, without trees and frequently
without bushes, but where the country rises and forms hills, it
is overgrown with trees. In the vicinity of the sea the soil of
these savannahs is light, loam mixed with a large propor-
tion of black mould. The higher ground, especially near
the banks of the river, and the lagunes, have a large mixture
of sand, and these trees are mostly overgrown with pitch-
pine, which in other places in the interior are composed of
dry impregnated sand mixed with mould, and in the woods which cover them a
large number of mahogany-trees, cocoa-trees, cacteouchouc,
and other valuable trees are met with.

The whole country, as far as it is known, presents a continual alternation of
wooded lands and prairies.

The Mosquito Coast is drained by numerous rivers, which
south of Cape Gracias a Dios run mostly to the east-south-
east, but north of it they run north-east. Many of them are
navigable to a considerable distance from their mouths, and it
appears that rapids are only found near their sources. But
the navigation is frequently impeded by the trees which are
brought down during the rainy season, and when the waters decrease
they are lodged in the bends of the river, where they are
accumulated so as to form a dyke across the current. They
are partly removed by the freshets, but are soon replaced by
other blocks, which, however, are only accessible to small vessels,
so that all those which do not fall into lagunes have bars across
their mouths, on which at low-water there are in general only
from one to five fathoms of water. As they enter these
rivers, which falls into the lagune of the same name (12°
N. lat.), and is said to run upwards of ninety miles, rises
within the state of Nicaragua. Wanks or Segovia River also
rises in the interior, and joins the Rio de la Segovia, and
Segovia. It is said to run 250 miles. Its mouth is near the
Bay of Cape Gracias a Dios, and has a bar; but the
river may be entered by a canal which unites it to the
bay. It is said to be navigable to the boundary-line of
Nicaragua.

The lagunes are a peculiar feature of this country. They
are not shallow, stagnant collections of water, but deep lakes,
connected with the sea by one or more straits, by which the
tide enters them. They generally receive one stream, fre-
quently several streams, and therefore a current is always
observable, which sometimes runs strongly. Near the entrance
of the lagunes the water is brackish, but in the interior, and especially the
springs, it is sweet. The trees which rise in these
lagunes form good harbours, but towards the
middle of the dry season barcts are found across the entrance,
which however have much more water than the bars of the
rivers. Owing to this circumstance, and because the lagunes
do not exale any dangerous vapours, the settlements
have generally been made on their banks. The most extensive,
from south to north, are Biewfield Lagune, into which the
Biewfield River falls,—this lagune is upwards of fifty
miles long, and from eight to fifteen miles across, and has
from three to four fathoms water on its bar; Pearl Key Lagune,
which is six miles long, and from sixteen to twenty miles
wide; the bay at the Cape Gracias a Dios, which is of small
dimensions, being only four miles long and three wide, but
which forms a good harbour, with 22 feet water at the
entrance and 20 feet in the interior, and excellent anchoring
ground; and Cardiaskia Lagune, west of Cape Gracias a Dios,
which is thirty-six miles long and from eight to ten wide,
and from two to three fathoms deep: the bar across its mouth
has only eight feet water, but it extends to the tongue of land
which separates the lagune from the sea, which changes
from two fathoms to two and a half deep. Four rivers of
moderate size fall into this lagune.

The Mosquito coast resembles that of Jamaica,
in having two wet and two dry seasons, but they do not
occur exactly in the same months, and differ somewhat
in character. The autumnal rains, which in Jamaica
continue in October and November, continue on the coast for
four months, from November to February. They are heaviest
in December, but even in that month only descends in
showers: continual rains for twenty-four hours are of rare
occurrence. The first dry season, about the middle of
August, is not so dry as in Jamaica, where they
sometimes continue for several days and nights without inter-
mission. On the coast the rains are heavy, but very short;
they however attended by very thunder-storms. From
the commencement of August to the middle of October is the
second dry season, in which only light showers occur at the
beginning and towards the end of the season. The rainy
months are November, December, January, and February.
The dry months March, April, May, August, and September;
and those in which showers alternate with dry weather,
October, February, and June. The annual amount of rain
which falls has not been ascertained, but it is certain that it
exceeds the average of Europe, though the number of rainy
days is not so large. In the coldest months (from September
to February) the temperature varies between 66° and 70°,
and descends occasionally to 60°, and even to 50°. In the
three following months it varies between 70° and 80°,
and rarely rises higher. In summer the thermometer ranges
between 75° and 84°, sometimes rising to 86°. In autumn the
range is between 70° and 66°. The temperature of the air in the
day and night is very small. The eastern trade-winds, not being stopped by mountain-
ranges near the shore, but passing over the inclined plane
of the coast, blow for three months without interruption.
There are occasional easterly fogs, and a light sea-breeze
which exists on the sea. To this circumstance, and to the
abundance of stagnant waters, the comparatively great salu-
arity of the climate is to be attributed, which is confirmed by
all modern travellers who have resided in the country, though contrary statements have been made
by modern writers. During the long rains (November to
February) northern winds prevail, but from the middle of
February they change to the south, and the general winds settle at the end of March, and during the three following
months they blow with considerable force. In August and
September they are light, variable, and interrupted by calms;
and in October the wind passes between east and north, until
it settles entirely in the last quarter. Dew is not frequent,
and never heavy, but the thunder-storms are sometimes
terrific. Hurricanes are not experienced, nor does it appear
that earthquakes, even of a slight kind, have occurred, though
most of the surrounding countries are frequently visited by
them, especially Guatemala.

Vegetation is as vigorous as in any country between the
equator and the Tropic of Capricorn. The principal trees are clad often
a height of five or six feet. The number of vege-
tables which are cultivated with success is great; the most
common are plantains, bananas, arrow-root, Indian corn, kola,
african tobacco, cacao, potato, tapioca, the different
kinds of palm, cotton, cassava or mandioc. Coffee, cocoa-nut trees, palm-
ioil trees, and orange and lime trees are planted; the woods
contain a great number of trees whose fruits are edible, or which afford timber and cabinet-woods, or are useful
in other respects. Such are the pine-apple tree, cabb-
bage tree, fan palm tree, cacteouchouc tree, avocado pear,
pimento tree, live oak, sepulchre tree, papaya tree, calabash
tree, mamey tree, guava tree, mango tree, cano tree, silk
cotton tree, mahogany tree, cedrella, yellow-wood tree, iron-
wood tree, dog-wood, ebo tree, cashew tree, lassa tree,
guaciao tree, pock wood, rosewood tree, the caracar oil plant,
brasiliare tree, the acajou, or true ironwood, the puiti oil
plant is found wild; vanilla and saracapella are gathered, the
last mentioned to such an extent as to afford a considerable
article of export.

Cattle are very numerous and of a large size; horses abond,
but they are not large; asses, sheep, and goats are not
kept, but hogs are abundant. Fowls are numerous. Several
kinds of monkeys are found in the woods, and in the
different rivers, where also the jaguar and the tiger-cat are met with.
Other animals are the racoon, the opossum, grey squirrels,
deer, and the marmot. Alligators are found near the embou-
ches of all the rivers. Lizards are very numerous, and
are distinguished by its size, and is eaten by the natives. There
are several kinds of snakes, which of these are said to be
poisonous. The land-turtles belong to the species Testudo
tabulatae, and are sometimes more than a foot long, but their
flesh is less esteemed than that of the sea-turtles, of which great numbers are always to be met with on the keys opposite the coast of the Cayman Islands. At the Cayman Islands there is a resort, where they take especially green turtles (Chelonia mydas) and hawks-bills (Chelonia caretta). The birds are imperfectly known. Among them are different kinds of pelicans (Pelecanus aquatorialis), humming birds, the black vulture or John crow (Cathartes adamsi), and several kinds of pigeons. Several kinds of ducks and the pelican (Pelecanus antiquorum) have been noticed. Fish is abundant in the lagunes and rivers. Fifteen species are caught in the sea, thirteen in the lagunes, and perhaps more than ten in the rivers. The shark and the saw-fish (Pristis antiquorum) are frequent in the sea and the lagunes, and along the coast there are also rays. No shell-fish have been noticed, except the oysters. Crabs, crawfishes, and some kinds of lobsters are frequently met with. Honey is frequently used as sugar. Mosquitoes are not common, which is ascribed to the strong winds that generally blow. Sand-sies, sand-dies, and centipedes (Scolopendra morbitana) are common.

The majority of the inhabitants do not materially differ from the other savage tribes of America. But the ruling tribe, called Sambos, show evidently a strong mixture with the negro. The colour of the other tribes is a clear brown; but that of the Sambos is much darker, approaching sometimes to black; and whilst the black hair of the former is lank, that of the latter is curly. In some cases the Sambos have also thicker lips, and are stronger built. There exists a tradition, that a vessel containing a great number of negroes was cast away on this coast, that the negro males were killed with muskets, and the negro women were carried away. Among them are also a few Caribbees, probably the descendants of those who, in 1797, were sent from the isle of Dominica to that of Roatan, and who afterwards emigrated to the continent of America. They are short in stature than the other tribes, but stronger built, have a somewhat convex nose, and are distinguished by greater vivacity and industry. All the tribes, though they speak different dialects, distinguish themselves from other nations by the use of the châtelaine, which the Europeans have changed into Mosquitoes. The natives of this country live mostly on the produce of their fields, on which they cultivate maize, cassava, yams, plantains, pineapples, coconut-trees, and some other fruits; but they eat also large quantities of fish, and the flesh of the wild animals which they kill, or of their cattle. They show considerable skill in making canoes, of which the larger kind, called dorés, are frequently six or eight feet wide, and from thirty to forty feet long. They are made of a single trunk of a tree. Though in general very indolent, the natives are good seamen, and have frequently earned the praise of English naval officers, who have traded with them and their canoes. They have also acquired some skill in weaving cotton-stuffs.

The commerce of the Mosquito Coast is carried on by a few English families which are settled there. They receive English goods in exchange for the produce of the soil, and also by vessels sent from Jamaica and other English settlements in the neighbourhood. Vessels from Jamaica and the Cayman Islands to the keys along the coast to catch turtles, also import occasionally a few articles. In this manner the natives are supplied with some coarse linen and cotton stuffs, with very indifferent guns, gunpowder, balls and shot, some cutting instruments, as axes, knives, blades, iron kitchen utensils, fishing-hooks, glass bowels, gossamer hats, American tobacco, pipes, flints, girdles, bowls, and mugs of earthenware, rum, brandy, and liqueurs. These articles are exchanged for cattle, especially cows, turtle-shell, hides and horns, sarsaparilla, vanilla, the sauchou, gummi, casco, pimento, castor-oil-nuts, mahogany, fruit, and some articles from the central American states: as cochineal, silver, gold-dust, and silver and gold coins. They demand in return the commodities of the United States and Spain, and some intercourse with Honduras and Nicaragua.

This coast was one of the first places where the Spaniards tried to establish a settlement. Alonso de Ojeda and Diego de Nicuesa, on an expedition to the coast of 1512, which was short, the adventurous; but the natives resisted the invasion with great perseverance, and the Spaniards were compelled to leave the country after having lost a considerable number of men. When the English and other European countries commenced trade, they had submitted to Davila (1522), and Pedro Alvarado (1523), the Spaniards again tried their arms against the natives; but they were not successful. They sent there in the seventeenth century several misadventures, some of whom died the death of martyrs. All those events increased the hatred of the natives to the Spanish name. When the buccaneers were in power in the seventeenth century, they were received by the Mosquito with some circumspection, and the Spaniards in the country as the safest retreat when they were pursued by the buccaneers. By means of the buccaneers it appears they were brought into connection with the English, and the old colony was again revived. This was confirmed by a treaty in 1670. The first settlement of Englishmen on this coast dates from 1730, when some families established themselves at Cape Gracias a Dios on Black River and at Blythewode's River. As these settlements soon acquired a certain degree of prosperity, especially by smuggling with the inhabitants of the Spanish colonies, the English government sent there some persons invested with authority, and erected a few small forts. The settlers were engaged to abandon these forts and to compel the colonists to leave the country. This was done, but several families established on Blythewode's Lagoon did not obey the order of the government, and remained there. It is stated that in 1770 the number of English settled on the Mosquito Coast amounted to 1400 individuals. These people were entirely abandoned by the peace of 1783, and were obliged to go to Belize. Soon afterwards the Spaniards made the last attempt to conquer the coast, by taking possession of the fort on Black River, which the English had abandoned. But they were totally defeated by the natives. England again took the coast under its protection, and induced the Spaniards to cede it, and in 1783 acquired their independence, that of Nicaragua claimed the Mosquito Coast as a portion of its territories, but these claims were rejected by England and the king of the Mosquitoes. It was at this time that the English first created the town of Falmouth and Port Royal, and treated the king as an independent sovereign in 1817, when he paid a visit to the town of Guatemala. It appears that at present the claims of the state of Nicaragua have been given up, with the exception of those which are situated between Punta Gorda and the Laguna of Chiquila.

Meanwhile the king, whose power is absolute, has ceded different districts with almost sovereign power to some Englishmen, who have formed settlements on the island of Great Inagua, and on the banks of Black River, but other portions have not yet been settled. It is probable that in course of time this country will become an English colony, especially as the native population has lately greatly decreased, nearly half of it having been swept away by the small-pox.

[Henderson's 'Account of the British Settlement of Honduras,' &c.; Roberts's 'Narratives of Voyages and Excurions on the East Coast and the Interoceania'; Young's 'Narrative of a Residence on the Mosquito Coast during 1830-1841'; and Bericht über die Untersuchung einer Theile des Mosquitoaldeas von der dazu ernannten Commis- sion of the 21st July, 1832.]

MOUFLON [Sheep, P. C.]

MOVING POWERS. The means employed to give motion to machinery, independently of the cases in which the force of gravity is used (such as ships upon rivers, and the pendulum of a clock, are the strength of men and animals, the pressure of the atmosphere, the expansive force of steam, and the action of wind or water; it is even probable that the recently proposed actions of the galvanic fluid and of fixed gunpowder will in time be numbered among motive forces for impelling carriages, vessels, or machines. The first and second of the powers above named have been treated under Animal Strength, P. C. S. and Atmospheric Railway, P. C. S.; and the force of steam under Steam-engine, P. C. P., p. 475 et seq.

The intensity of a moving power is always estimated by the amount of the resistance which is overcome and the space through which the equivalent, cast of that resistance is conveyed, or raised vertically, in a given time. Thus, in the article on Animal Strength [P. C. S.] it has been shown that a man, a horse, a car, &c., are resisted, expressed in pounds, through a certain number of miles during a working day and the continued product of the weight, the distance, and the time has been made to denote the intensity of the power, one pound being one foot, one mile the distance, and one hour that of time; in estimating the action of an engine or machine it is usual to consider one foot as the unit of distance and one minute as the unit of time, one pound being the weight, and Nicoli's relation, the action of the power, is, moreover, supposed to be continued during all the time that the machine is at work.

Originally the large kind of engines, except such as were impelled by wind or water, were moved by the power of horses; and when other agents were employed, the gross effect of the
MOY

333

MUC

engine was estimated by the number of horses to whose action it was equivalent; but the intensity of horse-power is very variable, and some inconvenience was at first, on that account, experienced in estimating the relative values of engines. In order to establish, conventionally, this universal unit, Means, Boulton and Watt ascertained from trials purposely made that a strong horse can draw 125 lbs. at the rate of 3 miles per hour during 8 hours; therefore the measure of the power may be expressed by 3000 lbs. (i.e. 125 X 3 X 8) drawn or raised one mile in 8 hours; or, multiplying by 5290, the measure is 15,640,000 lbs. raised one foot in an equal time. This product, being divided by the number of minutes in 8 hours, gives the rate of the centre of percussion to the vessel at each stroke; and hence, when raised one foot per minute continually; and the last number is now universally adopted as a measure of the intensity of the power of a horse. Therefore when an engine is said to have the power of any number n of horses, it is understood that it is capable of raising 38,000 n pounds' weight to the height of one foot in every minute during the continuance of its action.

The method of estimating power by a weight carried or raised through a certain space in a certain time is capable of being applied to all engines: thus, in drawing a carriage along a road, the resistance of the carriage must be equivalent to some weight; and the reaction of water against the paddles of a steam-boat may be more or less represented by a certain weight which, if it were lifted by the wheel, would oppose a resistance equal to that of the water. For the useful force of steam-engines in terms of the volume of water evaporated, the pressure of the steam, the length of the stroke, &c., see Steam-Engine, P. C. F.

Wind and water are employed as prime movers by means of the momentum arising from their velocity; and the latter, occasionally, by the pressure arising from its weight. The manner in which the force of wind is made to act in giving motion to vessels on the surface of the water has been fully explained under Sail, P. C., and, in producing the revolutions of windmill sails, under Wind-Sail, P. C.; it is intended, therefore, in this place, merely to explain the method of forming an equation of equilibrium for the power of an oar in giving motion to a vessel, and to show the force of water on the paddles or flat-boards of wheels which are turned by that element. Let M N represent one side of a vessel, A B the position of the oar when its blade enters the water, and E the fulcrum or side of the rowlock against which it presses; then since the vessel will move forward during the time that a stroke of the oar is being made, let F be the position of the fulcrum and C D the position of the oar at the end of the stroke: if the vessel had remained at rest, the oar, at the end of the stroke, would have had the position C D, which may be considered as parallel to C D.

Now, B being the centre of percussion on the blade of the oar, the actual motion of B (supposed to be parallel to the keel of the vessel) may be represented by $\overrightarrow{B D}$ while the movement of the vessel is $\overrightarrow{E F}$ (i.e. $\overrightarrow{D}$); and therefore $\overrightarrow{B D}$ represents the relative movement of B. The lines $\overrightarrow{B D}$ and $\overrightarrow{D}$ being proportional to the velocities of the oar and vessel, we may represent by $\mathbf{a}$ and $\mathbf{v}$; $\mathbf{e} - \mathbf{v}$ will express the relative velocity of the oar, and the effective power of the latter will vary with $(\mathbf{v} - \mathbf{e})^2$. Let $\alpha$, in square feet, be the area of the blade of the oar, and let the pressure of water against a square foot of surface be 18 lbs. when the velocity of the water is 1 foot per second; then $\frac{1}{2}(\mathbf{v} - \mathbf{e})^2$ will denote the force of the oar.

If, for simplicity, the prow of the vessel be supposed to have the form of a wedge with plane faces meeting in a vertical line, or cutting water, on putting $\mathbf{a}$ for the area of the whole prow and $\theta$ for the inclination of each face to a vertical plane passing through the keel, we shall have

$$\frac{1}{2} \alpha \sin \theta \mathbf{v}^2$$

for the resistance of the water against the prow. Therefore, $n$ being the number of oars all of which are supposed to act with equal forces; we have, when the vessel has acquired a terminal velocity,

$$\alpha = \frac{1}{2} n (\mathbf{v} - \mathbf{e})^2 \sin \theta \mathbf{v}^2,$$

from which $\mathbf{v}$ may be found. The velocity of a vessel moved by oars is, however, found to increase in a less ratio than the number of oars.

The power of the oar in rowing appears to be diminished by the reaction of the feet of the rowers in pressing against the foot-boards; this has a tendency to force the vessel backwards, but it is compensated by the greater velocity which the vessel thereby gains. Some force, however, is lost in overcoming the inertia of the oar, and in bringing it forward against the air; this last force is considerable when the vessel is rowed against a high wind, though it is to a certain degree diminished by the practice of feathering the oars.

The above equation might be used to determine the velocity of a vessel impelled by steam, in which paddle-wheels are employed, if it were possible to determine, nearly, the value of $\mathbf{n}$, or the number of square feet of paddle which, on both sides of the vessel, are at every moment acting efficiently against the water: the value of $\mathbf{e}$ would be, of course, determined by the revolutions with which the paddle-wheel is turned, at a given time; and it should be expressed by the number of feet per second which the centre of percussion in the paddle moves through in turning about the axis.

The momentum of water flowing horizontally against a plane, such as a flat-board of an undershot wheel, depends on its velocity, on the area of the surface with which it comes in contact, and on the obliquity of that surface to the direction of its motion; and, in estimating the effect of water on such a wheel, it is necessary to determine from the dimensions of the channel and the velocity of the water in it the weight of water which descends vertically through a certain height, as one foot, in a given time. The weight of water, multiplied by the height actually descended, being compared with the product of the number of pounds which the wheel can raise to a certain height in the same time multiplied by that height, expresses the power of the water in force. In experiments Mr. Smeeaton concluded that, when the quantity of water expended is the same, the useful result varies nearly with the head of water, or with the square of its velocity.

The power of an overshot wheel is estimated by the product of the weight of water expended in a given time multiplied by the whole weight of its descent, that is, by the sum of the diameter of the wheel and the height of water in the reservoir above the top of the wheel. The useful effect of an undershot wheel is said to be nearly double that of one which is undershot.

In determining the power of water on breast-wheels, it is customary to consider such a wheel as one compounded of an undershot and a breast-wheel; and the effective power of the latter to be equivalent to that of an undershot wheel whose head of water is equal to the difference in height between the surface of the water in the reservoir and the point at which the water impinges on the breast-wheel. The height of water above the wheel whose height is equal to the difference between the point of impact and the level of the tail-water.

MUCID ACID. [Chemistry, P. C.]

MUCIUS SCAEVOLA. [SCAVEOLA, P. C.]

MUCUNA, a genus of plants belonging to the natural order Leguminosae. The calyx is campanulate bilabiate, with two very caducous bracteae as long as the tube; the upper lip broad, entire, and obtuse; the lower lip trifid, with acute segments. The corolla is papillose-lobate, with a corotiate vexillum incumbent on the wings, much shorter than the wings and the keel, and without callosities. The stamens are diadelphous, with five of the androecium oblong, linear, and the other five ovate and hairy. The seeds oval, roundish, or reniform, with a narrow, oblong, or linear hilum. The species are climbing herbs, with pinnate or palmate leaves and axillary racemes, which hang down bearing fruit.

M. pruriia, Cowitch, has purple flowers in compact ovate racemes, leaflets hairy beneath, the middle one rhomboidal and obtuse, the lateral one dilated or ovate. The legumes are oblong, curved, compressed, not keeled, and covered all over with a thick coating of erect, white, stinging hairs, which turn black in drying and brown when ripe. It is a native of India, and found also in the western portions of the United States.

M. pruriens, Common or Stinging Cowitch, has entire ovate acute leaflets, smooth above, hairy beneath, the lateral ones oblique at the base, the middle one slightly rhomboidal

Christian Müller engraved only eighteen plates, but the Madonna di San Sisto is in itself a host, and exhibits him at least the equal, if not the superior, of Raphael Mengoni, to whose works he clearly may compare, and his edition of Droysen's 'The Greek and Latin' (Leipzig, 1833, 4to.), and his monograph of Thucydides (Leipzig, 1833, 8vo.), and of the Eumenides of Aeschylus, are equally valuable.

In 1840 Müller, who had long desired to see the countries to the investigation of whose history, literature, and art his whole life had been devoted, resolved to visit Italy and Greece, partly to convince himself of the correctness of the results at which he had arrived, and partly to collect new materials. His activity in Greece was of very great assistance to him, in 1841, while engaged in making some excavation at Delphi, he was seized with a fever, in consequence of which he died soon after he had returned to Athens. He was buried in the Ancient Academy of Athens, posthumously taking place for a scholar like Müller that could have been devised.

Müller was a man of the most extensive and varied acquirements, and of a keen and penetrating judgment. He acquired a European reputation at a comparatively early age. His numerous works, however, are not all of equal merit, and the two faults more particularly to be noticed are his great haste in the composition of his works, and a tendency to theorize and generalize on insufficient grounds. But in extent of knowledge and reading there scarcely ever was a scholar who surpassed him.

MüLLER, WILLIAM JOHN, one of the best of the English landscapists, was born in London, the son of his father at Bristol, in 1812; his father was curator of the Bristol Museum. Müller's first instructor in art was the landscape painter J. B. Pyne, likewise a native of Bristol, but he owed his excellence to his instructor, the great Grünewald, and, and his great teacher was nature: he found an early and valuable patron in Mr. Acrman, of Clifton, for whom he painted many pictures. In 1835 and 1836 he made a tour upon the Continent, in which he gathered to himself all the many admirable sketches. Sketching from nature was a department of art in which Müller had extraordinary power; nearly all his more considerable works of this class are in themselves complete; they require no elaborated copies to make them presentable as pictures; he did indeed elaborate very few of them into pictures, and some of these rather lost than gained by the process.

In 1836 he exhibited a picture of Peasants on the banks of the Rhine waiting for the Ferry-boat, but it was a piece of no pretensions, and attracted little notice.

In 1855 he started upon a long and archaous tour through Greece and Egypt, and visited the important sculptures and paintings, and visited the mummy-caves of Mahadhibes, of which and many other interesting places in Greece and Egypt he made masterly drawings. He returned to England towards the close of 1839, by the Cretan coast, and to this period several admirable pictures of the remarkable scenes that he had sketched during this his first oriental tour. He had in the exhibition of 1840 Athens from the Road to Marathon, and the Memnon, or Ruins at Gournia in Egypt at Sunset, both pictures of the highest degree of merit, but in different styles. The Memnon, though hung high up in the dark octagon room in the Academy, commanded the attention of every one who could see so high; it is a master-piece of colour and effect, and is certain a work of high poetic art. The view of Athens is equally excellent in its class; the picturesque, and at the same time the historical associations connected with the place, make it an additionally interesting work: this picture, for which Müller received only thirty guineas, for his works had not yet attracted a moity of the attention which they deserved, was laterly purchased by a picture-dealer for nearly ten times the amount, and was sold for twenty-four guineas: ten times the amount is nearer its present value also.

In 1846 Müller joined on his own account Sir Charles Fellowes on his expedition to Lycia, to remove to London the Xanthian marbles, now in the British Museum. He returned to London in 1844 with some dozen of very interesting and masterly sketches, which elicited the unqualified admiration of all who saw them at the Society. Leaving the Graphic Society shortly after his return. About three hundred sketches and other works were lately sold by auction by Messrs. Christie and Manson, and they realized the enormous sum of
4800, a small sketch of his own apartment at Macri alone fetched sixty-five guineas. These are curious facts: he himself receives only thirty guineas for his picture of Athens, a finished work. He finds it, he says, far better to employ a footman, and be months subsequently a small water-colour sketch of his own apartment, which probably he himself would not have valued at much more than thirty pence, is sold for more than double the price. The living work would appear to be more worth the shadow of his own body when dead.

The pictures, the fruits of Müller's second tour, which were exhibited at the Royal Academy in 1844, appear to be the principal causes of his death. After the early failure and unexpected death, though the fatal results of their bad hanging on the Academy walls betray an extraordinary degree of sensitiveness in the painter. He appears from his own words to have anticipated such a result. He speaks of a violent protest against the exhibition of these works in the Academy; far indeed however was the result from the anticipation. Müller sent the following five pictures to the Academy exhibition of last year (1845) — Great Cannon formerly belonging to the Knights Templars, Rhodes; Head of a Chinari, Xanthus; The Burial-ground, Smyrna; Tent Scene, Cingaries playing to a Turkish family, Xanthus; and Turkish Merchants with Cannels passing the river Manganese, in the valley of Xanthus. These were, with one exception, what is called hung out of sight; that is, either so much below or so much above the line, that they were not or could not be seen, and might have been altogether spared over by the majority of visitors to the exhibition. Müller felt this condemnation excessively, and notwithstanding his own professed resignation to his fate, he was evidently aggrieved at the alteration. These pictures were exhibited in all the month of May, which ended fatally at Bristol, on the 5th of September following. He died from enlargement of the left ventricle of the heart, and several of his friends have not hesitated to declare that the humping committee of 1845 killed William Müller. In his own complaint however he was more moderate; he wrote as follows to his friends in the month of May, after the opening of the Exhibition:—A man honourably leaves his country, he risks other and distant climates, spends large sums of money, and, after labour and fatigue, he returns to his home, and produces pictures acknowledged to be superior to his former works. His ambition leads him not to expect too high a reward — only places where his pictures may be seen. Such had been my hope; and I find my Turkish Burial-ground and Xanthian Tent Scene on the very top, (at least the first named) of the large room, conspicuously obscure. My large picture is not so badly hung (six feet or more above the ground), but in such a place that one may expect but little from it. . . . Such has been the reward I have received for the expenditure of large sums, of great labour, the risk of loss, the expectation of a time-consuming and exhausting of a long journey—such are the rewards, or post of honour, a protected body afforded to the young English artist! the top row of the large room. These and other extracts from the letters are published in the 'Art Journal,' in which are also several letters written by him while in the East, containing a short account of his proceedings, and some interesting details relating to the ruins, and the customs of the people, in Asia Minor, illustrated with several sketches.

Müller exhibited several pictures at the British Institution, among which were, in 1845, a View of Rhodes with the Basha's Palace, and a Dane at Xanthus. He exhibited also many excellent landscapes in the early part of his career at Bristol; and, besides what has been already mentioned, the following works at the Royal Academy: —In 1841, Sketch of a sand-bank off the coast of Gibraltar; Copy of a drawing by the Sphinx: in 1843, Arabs seeking Treasure; Prayers in the Desert; and Welsh Mill on the Dolgarey. He published in 1841 a beautiful work entitled 'Pictureque Sketches of the Age.' This is an entire series of his Sketches in the East will also shortly be published.

MUN, THOMAS, is the name of an English writer on political economy, who lived in the earlier part of the seventeenth century. Some of whose writings appear to be known. His best known work, a small octavo volume, published at London in 1664, is entitled 'England's Treasure by Foreign Trade,' or, the Balance of our Foreign Trade is sotrecht, and the rate of it will be the rule of our great. Thomas Mun of London, merchant, and now published for the common good by his son John Mun of Beartsted, in the county of Kent, Easre. This title-page comprehends nearly all the particulars we have been able to discover respecting Mun. The book is dedicated to Thomas, Earl of Southampton, in an address in which Mun's son says: — It was left me in the nature of a legacy by my father, for whose sake I cannot and will not desert. To these Mun gratefully dedicates his book, and to his lordship, and to the public. Mun is a name well known amongst merchants, and well known to most men of business for his general experience in affairs, and valuable insight into trade. . . . There is little probability that he was the same man who observed that Ferdinand I, the Grand Duke of Tuscany, was very rich in treasure, and enlarged his trade by lending to merchants a great sum of money at a low interest, he adds: — Myself, I have heard the story of his munificence; although he knew that I would presentily send it away in specie to Turkey, to be employed in wares for his country; he being well assured that in this course of trade it would return again, according to the old saying, with a dwitting in the mouth. By his thus encouraging of commerce, within these thirty years the trade of his port of Leghorn is so much increased, that, of a poor little town, and myself knew it, it is now become a fair and strong city.' Ferdinand I, died, after a reign of twenty-two years, in 1609; it is strange, therefore, that Mr. Macpherson, who quotes this passage in his 'Annals of Commerce,' has not observed that 'probably Mr. Mun was in Leghorn at that time and may have written his book about 1600.' The conjecture of Mr. M'Culloch ('Principles of Political Economy,' p. 30), that at the time when Mun wrote his book, 1629 or 1640, is likely to be much nearer the truth. Mun, being, as we have seen, a foreign merchant of the highest eminence before 1609, can hardly have been born later than 1600, and most probably was dead long before 1660. His 'England's Treasure,' is addressed to his son, and begins: — My son, in a former discourse, I have endeavoured, after my manner, briefly to teach thee two things: the first is piety; the second is policy; so and now I am to speak. But whether this former discourse was even published we do not know. Mun, however, has always been understood to be the writer of a work entitled 'A Discourse of Trade from England to the East Indies, by T. M.' 4to. London, 1621.

The object of this last-mentioned work is to defend the East India trade from the charge brought against it of exhausting the national wealth by occasioning an annual exportation of treasure, or of gold and silver, or for a moment doubt, that the true profit of the country upon any branch of commerce is to be measured by the balance of money which it annually brings into the country; but he was, however, justly observed by himself, would upon this principle be a losing trade, yet it became in reality profitable in consequence of the exportation of certain commodities which it enabled us to make on other East India. Every year we are sending back every year a much larger amount of treasure than we sent out to India. The reasoning is the same that was afterwards employed by Sir Josiah Child in his anonymous pamphlet, 'The East India Trade, a most profitable Trade to this Kingdom,' published in 1677. The same doctrine is also expounded in Mun's other work, his 'England's Treasure by Foreign Trade,' the fourth chapter of which, principally relating to the East India trade, is headed, 'The exportation of our monies in trade of merchandize is a means to increase our treasure.' The fundamental principle of that work is stated in the second chapter:—'The ordinary means to increase our Treasure is by the exportation of such articles as the English merchant, or every man who engages in foreign commerce yearly expressing merely the writer's agreement or dissent.

MUNDAY, ANTHONY, must, according to his epitaph, have been born in 1656. His early life is almost totally unknown; but he was at one time abroad, and describes himself

her by the

Execution of certain Traytours at Tizborne the 26th and 30th days of May, 1592; gathered by A. M., who was there present.

"He had, it appears, held a dispute at the foot of the gullows with many frequenters of plays, and also of pageants for the corporation and companies of London. Ben Jonson, in 'The Case is Altered,' written early in 1659, ridicules him and his city-shows, in his character of Anthony Baldinino, making this personage to say of himself, that he supplies the place of pageant-poet to the city of Milan when a worse cannot be had, and that he uses as much state stuffs as any man does. Perhaps Ben's critical acumen was a little sharpened by the fact that Monday had just been called our 'best player,' during the 'Mere's' Palladin Tamie, in which Jonson's own name is not mentioned. Mr. Collier enumerates fourteen plays which Munday wrote or assisted in writing, desiring however to add to this heroic list the plays of 'The Puritain, or the Mere,' 'The Earl of Robert Earl of Huntingdon,' by Anthony Munday and Sir Charles Hackett, both acted in February, 1598, and printed in 1601. Both are reprinted in Collier's 'Supplementary Volume to Doddson's Repertory.' The performance of these pieces, possessing much vigour of painting, and presenting, in the scenes with Robin Hood's band in Sherwood Forest, some pleasing poetry. 3. 'The Widow's Charm,' acted in July, 1603, was dedicated to the memory of 'The Poet,' or 'The Widow of Waffling Street,' which was printed in 1607, and has been absolutely ascribed to Shakespeare. 4. 'The First Part of the Life of Sir John Oldcastle,' by Anthony Munday, Michael Drayton, Robert Wilson, and Richard Hattery; published twice in 1600, one of the editions attributing it to Shakespeare. Munday died on the 10th of August, 1633, and was buried in the church of St. Stephen, Coleman-street.

MURAT. CAROLINA MARIA ANNUNZIATA BONAPARTE, sister of Napoleon, born at Ajaccio, in 1782, married in 1802 General Murat, then aide-de-camp to the First Consul, and became Princess of Berg, and afterwards Queen of Spain in 1808. She was the only daughter of Napoleon who became a queen. She took a considerable part in the public affairs of the kingdom of Naples, and was several times regent in the absence of her husband, who was compelled to follow Napoleon in his never-ending wars. She displayed much ability, prudence, and firmness; she encouraged education and learning, and founded several useful institutions, among others one for the education of young ladies at Naples, which still remains. She had at various times a difficult task in acting the part of a conciliator between her spirited and imprudent husband and her imperious brother. After seven years of reign, during which she showed herself worthy of the crown, she was obliged, through the reverses of her husband in 1815, to leave Naples on board of an English man-of-war, and to retire to Austria, where she lived for many years. She died on the 16th of November, 1855. Madame Murat made a journey to Paris after 1830 for some family interests, and was well received by Louis-Philippe and his family. She afterwards went to Monte Carlo, where she afterwards lived in poverty. Madame Murat had a very favourable opinion of his sister Caroline.

(Lettre, Anniv.)

MURÉNA, an apodous malacocephalous fish of the family Anguillidae, Bowd., found in the Mediterranean and Portuguese seas, and in one instance has been taken on the coasts of Britain. It grows to the length of between four and five feet, and even more. The body is smoothly scaled, with the exception of five lateral rows of small tubular fins. The orifrices of the gills are small and open, one on each side. In each jaw there is a single row of teeth. The dorsal and anal fins are very low, and are united. The Muréna Heliosa is the type of the genus. It is found in the P. S. C., N. 155.
with his Euclid and algebra. Mr. Brown, who was then employed in a parish in which Mr. M. C. was, a Cambridge Master of Arts, was the proprietor. This last-named gentleman, being then about to visit England, promised to take some of Murphy's papers with him, and to do what he could to bring them to the notice of Professor Wollaston, who had made various contributions to the Mathematical and Physical Repository. The first answer was not very encouraging. Mr. Woodhouse would say no more than that if they would send the boy he would look after him. On being requested to look over the papers, he declined, saying, that he had no time, and made it a rule not to do so. He desired that the papers might be taken away, and on being requested to allow them to remain, to meet the case of his possibly being able to look at them, he predicted for them the fate of waste paper, and the interview ended. In six weeks from that time, however, Mr. Woodhouse wrote a hurried letter to Mr. McCarthy, stating that at the moment when he was about to tear the papers, in fulfilment of his prophecy, his attention was struck by something that was almost new to him—that on turning page after page, he saw with delight so much talent that he was really unable to say he had continued to fix his attention on it. He had not at first found his genius unacquainted with any amount of genius and industry, unaccompanied by strict attention to the University course of reading: and Mr. Murphy's time, though occupied by speculation, came out third wrangler. The highest place is sometimes not to be gained by any amount of genius and industry, unaccompanied by strict attention to the University course of reading. In 1829 he took his bachelor of arts degree, and at once entered third wrangler. 

Mr. Murphy began his residence at Calais College, in October, 1825. During his residence, the college supplied him with money, in addition to the proceeds of his scholarship. In 1829 he took his bachelor of arts degree, and at once entered third wrangler. The highest place is sometimes not to be gained by any amount of genius and industry, unaccompanied by strict attention to the University course of reading. to a high standard in point of clearness of exposition, and are besides based on a wrong principle, that of teaching the pupil how to write good English by placing before him specimens of it. His Specimens of English are, consequently, very obscure, and rules are laid down without explanation of the principles on which they are founded, and if the pupil commits the definitions and rules to memory, believes in them, and can apply them, his grammatical education, as far as these works are concerned, is considered to be complete. But grammars of this class still supply the wants of the present age, even for the purposes of common school instruction, and ought to be superintended by a better kind, in which the principles of the language should be explained, as well as illustrated by specimens selected from the best writers. Murray's Grammar is altogether deficient in the etymological part, and his dissertation on the sounds, his grammar of words, and his grammar of their kindred, show a lack of knowledge of the true forms of words and their historical deduction from the early state of our language. His next publication was a series of extracts called 'The English Reader,' to which he soon afterwards added an 'Introduction,' and a 'Sequel,' the three volumes containing respectively selections suited to pupils of different degrees of maturity. The success which attended these publications induced him to publish the 'Lecteur François,' in 1792, and in 1797 an 'Introduction to the Lecteur François,' which he published a Spelling-Book. For the copyright of all these works he received a liberal price, and as he had no children, and his property was as much as he and his wife required, the income from them, with the interest of other editions that were issued, was about £15,000. In 1806 he published an enlarged edition of the Grammar and Exercises, in 2 vols., designed for the use of persons who might desire it worthy a reference to the 'History of English Grammar,' the 'Lecteur François,' the 'Homme's Commentary on the Psalms,' 12mo., and a little work, published in 1817, 'On the Duty and Benefit of a frequent and serious Perusal of the Holy Scriptures.'

Murray's thorough knowledge of his business for so many years to bodily infirmity as well as to some severe attacks of disease, continued to live till his eighty-first year. He died Feb. 16, 1826, with the reputation of being an exceedingly kind and accomplished man. (Memoirs of the Life and Writings of Lindley Murray, in a Series of Letters written by himself; with a Preface and Continuation of the Memoirs, by Elizabeth Frank, York, 1826.)

MURRAY, JOHN, publisher, born November 27, 1778, died June 27, 1843. His father, originally an officer of Marines, whose name was MacMurray, purchased (1768) the business of Paul Sandby, 32, Fleet Street. John Murray was educated at several schools—at the High School of Edinburgh, at Kensington, at Dr. Burney's at Gosport, where he lost the sight of an eye by the accident of the writer's talents being suggested by his uncle, James Murray of Loughborough House, Kensington. At the age of fifteen he lost his father, a great misfortune, as it left him without control and direction; his mother married again, and his education was in considerable measure conducted by a medical bookseller, in partnership with Mr. Hightley, having dissolved the partnership in 1803, he soon devoted his attention to a wider field of literary business. The son of an old friend and neighbour, Dr. Rennell, Master of the Temple, Mr. Stradford Canning, with some other youths at Eton, had commenced a periodical called 'The Miniature,' which brought them some fame, but left them under loss. Mr. Murray, with a good nature which always distinguished him, and with something of that tact which enabled him, in his subsequent career, to seize upon occasions of cultivating powerful friends, on hearing of their situation took the copies off their hands, paid the expenses, and though he found little demand for the work, offered to print a new edition. Through the friends thus made, he became known to Mr. Canning. In September, 1807, he wrote to that gentleman opening to him the plan of the 'Quarterly Review,' as a means of countering the political influence of the 'Edinburgh.' While maturing his project—the most important undertaking of his life—it chanced that a severe criticism on Scott's 'Marmion' appeared, which was not made evident in the 'Edinburgh Review.' Mr. Murray instantly started for Scotland, was introduced to Scott at Ashiestiel, in September, 1808, found in him a warm supporter of his intended review, and through the aid of Mr. Scott and the influence of his friends, Hebers, George Ellis, Canning, Barrow, and Mr. Gifford, the editor, the publication commenced in 1809, and soon attained a circulation of 12,000 copies.

The most alliance of business and friendship long subsisted between Mr. Murray, and Constable of Edinburgh, and the Ballantynes; but he early perceived the result of its hankering after a cheap model of 'Waverley,' forego ing the great advantages of the connection, after repeated and strong warnings and remonstrances, he separated from them. He published, however, 'The Tales of My Landlord,' and 'The Last Hero of Scotland,' besides 'Waverley,' nor did he ever entertain any doubts on the subject. In 1810 he was sought and made the acquaintance of Lord Byron, giving 600l. for the two first cantos of 'Childe Harold,' which had been refused by another publisher. In 1812 he removed to Albermarle Street, where, increasing the number of his friends and literary connections, he soon surrounded himself with a circle of congenial characters. In the afternoon might be found in his drawing room, Scott, Byron, Campbell, Wm. Spencer, R. Heber, Gifford, D'Israeli, Mr. Ward (Lord Dudley), Canning, Hallam, Croker, Barrow, Madame de Stael, and, a few years later, Crabbe, Southey, Belzoni, Washington Irving, Lockhart, and many more.

His acquaintance with Byron extended over a period of more than ten years, and that close correspondence with him is printed in Moore's Life of Byron, where will be found more than one proof of his liberal mind. Having heard in 1815 that Lord Byron was in pecuniary difficulties, he sent him a draft for 1000l. for 'Childe Harold,' which he received on the course of a few months, and offering to sell the copyright of Byron's works for his use, if that were not sufficient. He abandoned the publication of Lord Byron's Autobiography, and, in 1824, he printed 'The Representative,' a daily newspaper—almost the sole undertaking of his life which proved a failure. It was attended with considerable loss, which fell entirely on him, and was soon given up. Among his valuable and successful publications were the expeditions of Mungo Park, Belzoni, Parry, Franklin, Donham, and Clapperton—the Family Library, begun April, 1826—the Domestic Cookery, of nearly 300,000 copies has been sold, the fortunate title having been secured in a dispute with the original publisher, for the 'Family Cookery Book'—and 'Deathbed Scenes.' The three last works, originally published by others, proved failures until Mr. Murray, perceiving their merits, took them into his own hands.

Bounded to the liberal-minded man of business and a gentleman, will be found in the Lives of Byron, Scott, and Crabbe, and especially in his modest 'Answer to the Calumnies of Captain Medwin,' appended to Byron's works.

The 'Quarterly Review,' the object of his pride and solicitude, was conducted from 1809 to 1825 by Mr. Gifford, since which, with the exception of one year (March to December, 1825), during which Mr. (now Justice) Peelridge was editor, it has been directed by Mr. Lockhart. Although the principles on which it was established and conducted, excluded the publisher from any interference in its management, yet his tact and perseverance in carrying out the objects in suggestion subjects for review, and in enlisting contributors, tended much to its popularity. He was an excellent man of business; and, when he really applied, could get through more work than most men. No one better understood how to measure the calibre of an author's genius, or the extent of his popularity, and few could be more skilful in timing a publication, so as to secure its favourable reception. His eminent merit—that which distinguishes him above the majority of his class—was that he dealt with the commercial department of literature in a spirit far above that of the mere dealer and chapman. Had he thrown away his capital and his talent, and given himself to the idle occupation of a publisher—a design which some think the especial duty of every publisher—a few years would have conducted him to ruin. But he did better than this. He indirectly encouraged all literary
effort by dealing honourably and generously with authors whose reputation was established, or of whose success there could be no doubt. This was not patronage, but equitable distribution of the revenue of the capital and the benefactors. He was distinguished too, by his careful avoidance of the low arts of puffing; he published, for the most part, books of worth, and his imprint alone gave a recommendation to a hook without it. Above all, he increased the security of advertising quacks. Mr. Murray continued to take an active share in his business until within a short time of his death. Although his health had been in a precarious state for some months preceding it, no warning was given of his death for three days before it occurred. Mr. Murray married in 1807 the daughter of Charles Elliot, bookseller, of Edinburgh, by whom he left one son, who continues his business, and three daughters.

MUSCA, a genus founded by Linnaeus in the reception of the Dipterous insects, commonly known as Flies. The Linnaean genus has been broken up by subsequent entomologists into many genera and even families. Of the typical family Muscidae no fewer than 1700 European species have been described by Melgen, and nearly as many more extra-European have been described by Rohnouin Desvoidy in a quarto volume of 512 pages, devoted entirely to this subject. Many of the Muscidae are interesting on account of their habits. Some of the species of Myobia deposit their eggs in the nests of Hymenoptera, so that their larva when hatched are found on stores of provisions there collected. The larva of Tachina are parasitic on other larvae. The adults of some other genera are found only in the dead bodies of particular species of animals, as Osmynota, which reside in the caskets of the dead. The blue-bottles and blow-flies, species of Lucilla and Calliphora, which continue by fly-blown. Anthomyia deposits its eggs in manure or in the roots of vegetables, and Tephritis in growing plants. The choose-maggot is the larva of an insect of this family named Psophila imbricata. Drosophila seallia deposits its eggs in fermented liquors.

Most of these flies are extremely prolific; the ovaries of the female flesh-fly (Sarcophaga carnaria) have been found to be arranged in spiral fashion and to contain as many as 20,000 eggs.

(Weastwood, Introduction to the modern Classification of Insects, and the writings of Melgen, Halloween, Desvoidy, and Maccurt.)

MUSCA/RI, a genus of plants belonging to the natural order Liliaceae. It has a globous or subhydridam perianth narrowed at the mouth and 6-toothed. The stamens are inserted at about the middle of the tube, the filaments not decurrent.

M. racemosa, Grape Hyacinth, is the only British species of this genus. There is also a species in Suffolk near Fakenham, and is found in some other parts of Great Britain. It has ovate nodding crowded flowers, the upper ones nearly sessile, abortive; the leaves linear, flaccid, and recurved. The flowers are on a short stalk. It grows most abundantly in sandy fields.

The bulbs of M. muschatus are, according to Lindley, emetic.

(Babington, Manual of British Botany; Lindley, Vegetable Kingdom.)

MUSCOVADO SUGAR. [Sugarc. F. C. P.]

MUSCULAR TISSUE. [Tissues, Animal, F. C. P.]

MUSEUM OF ECONOMIC GEOLOGY. This institution owes its origin to the suggestions of Sir H. T. De la Beche, who, in 1835 submitted to the Chancellor of the Exchequer, that the persons employed in the Ordnance Geological Survey had constant opportunities afforded them of collecting materials illustrative of the application of geology to the useful purposes of life, and of the material wealth of the kingdom. The advantages which would arise from such a collection, and its exhibition to the public, under the care of the Royal Institution, had been grasped by the gentleman and the ladies of the public, between the hours of ten and four in the morning, and ten and five in the evening. The principal officers to the establishment are Sir H. T. De la Beche, already named as the Director, Mr. Richard Phillips, Curator, and Dr. Lyon Playfair; Mr. Robert Hunt is keeper of the Mining Records.

The objects contemplated in the arrangements which have been effected were—to obtain specimens of the various mineral substances used for the construction of public works or buildings, or for road-making; of such as are employed for useful or ornamental purposes in the arts, or from which the useful metals are extracted; these being arranged with reference to the times when they would be advantageous, either in a scientific or practical point of view.

With respect to building-stones it may be observed in illustration of the utility of the establishment, that there exists in it a collection, described by appended tickets, of the various specimens of building-stones, procured by the commissioners appointed in 1838, to visit the quarries and examine the quarries of the stone to be used in the New House of Parliament. These specimens, with the very elaborate report in which their properties are described, cannot fail to be a source of great and lasting utility to the architect who seeks for information.

In addition to these specimens there are also exhibited numerous polished granites, porphyries, and marbles from various parts of the kingdom; some of the specimens are turned into columns, and others formed into vases.

Another object intended to be effected by the formation of the Museum is the promotion of improvements in agriculture, by exhibiting sections of strata, with specimens of soil, and the rocks from which they have been derived, or disintegrated, or in which they have been produced. It is intended, by this department of the Museum more especially, to exhibit the relations of geology to agriculture by imparting such a knowledge of the mineral strata as may suggest the means of permanent improvement on the surface. As constituting a large and most important proportion of the mineral riches of the empire, the Director has been especially careful in collecting specimens of these strata from every part of the kingdom, and the public have liberally contributed to this and indeed to every part of the institution.

An annual grant is voted by Parliament for geological sections of railway constructions, a service of much importance, especially in the mineral districts.

The Museum contains an extensive collection of the various metallic ores of Great Britain, with specimens of the results of the metallic processes by which they are raised; those of copper, zinc, lead, and silver, accompanied with illustrations of many of the purposes to which the metals are applied.

The application of various earths and metallic oxides to enamelling, and the manufacture of glass and of porcelain, is illustrated by specimens of the art of different ages.

It is to be further observed that a laboratory forms another department of the Museum; in this the analysis of soils and minerals is performed for the public on very moderate terms, and pupils are admitted into the laboratory for instruction in analytical and metallurgic chemistry.

In the Mining Record department are deposited plans and sketches of mines and quarries, the works and sections, and the modes of the machinery by which they are worked; it also contains works and sections in which many of the models have been constructed; and collections of mining tools used in several of the different countries are also exhibited. The department having of course the objects by which concern particular parties, rather than the public generally, is, from the nature of its contents, not open to indiscriminate admission, but every reasonable facility is afforded to all operative miners as well as the owners or agents of mineral properties, by application to Mr. R. Hunt.

In concluding this brief sketch of the Museum, we may observe that, owing to the great liberality with which it has been supported by the government and by the public, it has been for some time past impossible to exhibit the accumulated specimens for want of room. It is understood that, on this account, Government is building a larger and more commodious house for the purpose, which will extend from Piccadilly through to Jermyn-street.

MUSHROOM. [Agaricus, F. C. P.]

MUSCO'RA, a genus of species, by Linnaeus, and Musco'ra, P. C.]

MUSCO/RA/PUM, a genus of fossil plants, the fruits only known. From the coal measures of Lancashire. (Brownrigg.)

MUSOWA, or MUSOWA. [Astrabia, P. C. S., p. 24.]

MUTILLIDE, a family of Hymenopterous insects corresponding to the Linnaean genus Mutilla. These bees belong to Lattreil. Some of the species are remarkable for the power of their sting. MUSI'ANO, GIRO'ALMO, an eminent Italian painter, was born at Acquasfonda near Brescia, in 1528. He was first instructed by G. Romantini at Brescia; he then turned his
attention to the colouring of Titian, and particularly to his landscape backgrounds. About 1550 he went to Rome, where he first attracted notice as a landscape-painter, and he was known as the "landscape-Christ." In 1573 Raffael painted his famous landscape Jomone. He however soon showed that he was equally capable not only in all departments of painting, but in other kindred arts likewise; and he became one of the first painters of his time, and in the characteristic grand style of the Roman school he obtained a place in the ranks of the greatest masters. Michelangelo himself pronounced Muziano to be one of the first painters of the age, when he saw his large picture of the Assumption of Mary, which he painted for the church of Santa Maria Maggiore. This picture was afterwards removed to the Appartamento de Principi in the Quirinale, or papal palace of Monte Cavallo, where it stood for a hundred years, but it was not seen there by Ramboud a few years afterwards. There was a Resurrection of Lazarus by Muziano in the Orleans Gallery at Paris, but as this piece was engraved by S. Valtell for the "Cabinet de Cronart," in 1729, as part of the Orleans collection, it cannot be the picture so much approved of by Michelangelo, unless the account of Titi is incorrect. When the part of the Orleans collection, of which it was one, was sold by auction in London in 1800, it fetched only fifty guineas: who the purchaser was, or where it is now, is not publicly known.

There are many of Muziano's works in the churches and galleries in Italy, and many in other countries. One of his works is in the churches of Sant' Ignazio in Rome, St. Peter's, in the cathedral of Arezzo, and the church of Santa Maria del Popolo; some of these pictures are executed in a style similar to that of the earlier works of Raphael. Muziano's paintings may be divided into two classes: one, historical or religious subjects; the other, small pictures of flowers and landscapes. The former are inferior to the latter, being executed in a more naturalistic style, while the latter are true masterpieces of landscape painting. Muziano's landscapes are characterized by their rich color and the delicate handling of the trees and foliage. His landscapes are often compared to those of Claude Lorrain, but Muziano's works are more delicate and refined.

The following are the remaining British species of this genus:

M. repensa, Mouse Ear, with narrow lanceolate teeth; of the corolla slightly emarginate, the pubescence of the stem spreading. Found in boggy places.

M. capitostra with narrow lanceolate teeth; the limb of the corolla equaling the tube, the lobes entire, the pubescence of the stem adpressed. Found in water places.

M. aureostris has an attenuated limb of the corolla longer than the tube, the root-leaves on long stalks pointed. Only found in Scotland on the summits of the Breadalbane mountains.

M. agrestis has calyx rounded below, deeply 5-cleft, closed when in fruit; the limb of the corolla longer than the tube, flat; the root-leaves bluish. Found in shady places.

M. arvensis, Field Scorpion-Grass, has the calyx half 5-cleft; the limb of the corolla longer than the tube, convolute. Grows in cultivated land and thickets.

M. collina has the calyx open and ventricose when in fruit. Found on dry bank.
**342**

**MYR**

_**M. persicolar**_ has the calyx closed and oblong when in fruit. It has small flowers, at first pale yellow, afterwards blue. Found in meadows and on banks.

_M. aerifera_, generally found in medicine or the arts. The British species are most desirable for cultivation, especially

_M. polystria_ and _repsus_. All the perennial species require moist situations, as the edges of ponds or ditches. Some of the species may be grown in pots among other alpine plants. The annual species will grow in a dry sandy soil or on old walls, where the seed may be sown. The other species may be propagated by dividing the roots.

(London, Manual of British Botany; Don, Gardner's Dictionary.)

**MYRIACANTHUS**

M. _Agersis_, a genus of fishes and fish-like animals, found in the lower silurián strata of Lampeter, in South Wales. (Murchison.)

**MYRICA** (the Greek _myrchos_), a genus of plants the type of the natural order Myricaceae. It has its flowers in catkins, which are composed of cone-like scales; 4 to 8 stamens. The fruit is a 1-celled 1-seeded drupe, and no perianth. There are several species of this genus, which are shrubs or small trees.

One species, _M. Gale_, the sweet Gale or Box Myrtle, is a native of Great Britain. It has lanceolate serrate leaves broader upwards, with a shrubby stem. It is a bushy plant, and the flowers are white or pink. The flowers are pink or white, and the leaves are fragrant when bruised. This plant is found on the Continent of Europe, and also in North America, under the same circumstances. The leaves are divided by a yellow atheral oil, of a feeble odor, and mild taste, which after a little time becomes slightly warm. The leaves were formerly used as a remedy against the itch, and when bruised are used amongst furs for the destruction of the moth. In decomposition they are employed for the destruction of bugs and other vermin. In Sweden they are used as a substitute for hops in brewing.

_M. cerifera_. Wax-myrtle or Bay-tree, has ciliate lanceolate leaves, sometimes entire, but more frequently toothed, particularly toward the end, somewhat pubescent, a little paler beneath, and generally twisted or revolute in their mode of growth; has a branching half evergreen stem, from one to twelve feet high. The small flower is formed by a cone rhomboidal scale, containing 3 or 4 pairs of roundish anthers, on a branched footstalk. The pistilliferous catkins which grow on a different shrub are less than half the size of the staminate ones, and consist of narrow scales, with each an ovate ovary, and two fimbriate styles. To these catkins succeed clusters or aggregations of small globular fruits, which are at first green, but then change to a bright red. The small flowers are surrounded by a yellow atheral oil, which incloses a dicotyledonous seed. The hard covering is studded on its outside with small black grains, and over these is a coating of hard white wax, fitted to the grains, and surrounds the fruit from the mature state. This plant is a native of woods in the United States of America. The bark of the root of this plant is acid and astringent; in large doses it produces vomiting, accompanied by a burning sensation in the throat. It is used as a stimulant and astringent. The wax of the fruit is collected and purified, and used for many of the purposes for which bees-wax and candles are employed. The wax has been occasionally used in pharmacy in the same way as bees-wax.

The fruit of _M. sapida_, a native of Nepal, is about the size of a cherry, and is pleasantly acid and estable. (Lindley, Flora Medica; Lindley, Vegetable Kingdom; Babington, Manual of British Botany.)

**MYRIOPHYLLETES**, a genus of fossil plants, from the coal measures. (Arctis.)

**MYRIOPHYLLUM** (from _mueros_, numerous, and _phyllon_, a leaf), a genus of plants belonging to the natural order Haloragaceae. It has monoeccious flowers; a 4-pated calyx; 4 petals fugitive, longer than the calyx in the staminiferous flowers, small and reflex, or none in the pistilliferous flowers; a 2 or 4-ovuliferous pistil, or 2 or 4 ovulae, in the fruit tetracentric, separable into 4 hard nuts. The species are floating aquatic herbs, rising above the water to blossom. The leaves are finely cut opposite or verticillate; the flowers are small, disposed in racemes, and in whorled spikes, the upper leaves being almost entire.

_M. verticillatum_, verticillate water milfoil, has the flowers all axillary whorled, the bracts pinnaflid. It is a native of Europe, in ponds, ditches, pools, and lakes, but never in running water. It is found in Great Britain, but is a rare plant, _M. spicatum_, spiked water milfoil, has the flowers whorled, forming a spike, the bracts pinnaflid, the spike erect when in bud. It is a native of Europe and North America, in ditches, lakes, and pools, never in running water; it is found abundantly in Great Britain. _M. aquatica_, water milfoil, has the spike drooping when in bud, and the fertile flowers in axillary whorls. It is found in ponds and ditches in Europe, in Great Britain rarely.

A bout ten other species of this genus from various parts of the world have been described. There are some that are employed in medicine and the arts, and they are only worth cultivating in botanical gardens. When it is wished to grow the tropical species, G. Don recommends that small parts 'should be taken up in the spring from a native pond, planted in a grove of water and be placed in the stove in order to preserve them in a living state during the winter, and in the course of the April or May next season, may again be returned to the pond in the mean time, where they will thrive much better than if grown all the year round in pans of water or cisterns in a hot-house.

(Own, Gardner's Dictionary; Babington, Manual of British Flora.)

**MYRIPRSTIS**, a genus established by Cuvier for certain tropical fishes of the family of Percides.

**MYRMELEON**, a genus of large neuropterous insects, the larvae of which are aquatic, and are said to catch their prey by means of pitfalls. Among the many accounts which have been published of their operations, one of the best and most recent is that given by Mr. Westwood, in the 'Academy' for 1825. (Don, Gardner's Dictionary.)

'Some larvae of the common species, _Myrmle- leon formicolus_,' writes that naturalist, 'which I brought alive to this country from France, afforded me ample opportunities for watching their proceedings. It is in fine sand and the larvæ make its pitfalls. When placed upon the surface, it bends down the extremity of the body, and then pushing or rather dragging itself backwards by the assistance of its hind legs, but more particularly of the de- flexed extremity of its body, it gradually insinuates itself into and beneath the sand, constantly throwing off the particles which fall upon, or which it throws with its jaws or legs upon its head, by suddenly jerking them backwards.'

_Discobolus._

**Proceeding in this manner, in a spiral direction, it gradually diminishes the diameter of its path, and by degrees throws so much of the sand away as to form a conical pit, at the bottom of which it then conceals itself, its mandibles widely ex- tended being the only parts that appear above the surface; with these it hews a hole in the sand to fall down to the hole is immediately seized and killed. When the fluids of the victim are exhausted the ant-lion, by a sudden jerk, throws the dry carcass out of the hole: should, however, the insect by any means escape, the ant-lion immediately commences throwing up the sand, whereby not only is the hole made deeper, and its sides steeper, but the escaping insect is probably hit, and again brought down to the bottom of the pit. It is chiefly upon ants and other soft bodied insects these larvæ feed. They are however capable of undergoing long fasts, for one of my larvæ re- mained from October till March without food. Previous to assuming the pupa state, the larva forms a globular co- coon of less than half an inch in diameter of fine sand, glued with silken threads spun from a slender telescopic-like spinneret, placed at the extremity of its body, and lined with fine silk. The cocoons are small, not being laden at all, and in- inactive, and with all the limbs laid at rest upon the breast. When ready to assume the perfect state, it uses its own mandi- bles, which are quite unlike those of the larva and image, to gnaw a hole through the cocoon, and thus itself partly through the aperture in which it leaves the pupa skin. Immediately upon assuming the perfect state, the abdomen is almost immediately extended to nearly three times its previous length. (See also the writings of Rösel, Reaumur, and Bonnet and Guilding.)

**MYRON**, one of the most celebrated gods of ancient Greece, a nephew of the Divine Poseidon, of which that among the Townley Marbles in the British Mu- seum is supposed to be an antient marble copy, was born at Eleutheria in Boeotia about 480 B.C. Myron was the fellow-
pupil of Polycleitus under Ageladas; he was therefore in the prime of life at about the time that Phidias died; and he lived at the height of his fame in Athens, where he was domiciled, at the commencement of the Peloponnesian war.

For the following account of this work, he first obtained a reputation by a bronze heifer, much celebrated by the poets, which gives Pliny occasion to reflect that men derive more good from the wit of others than from their own. He made also a dog: a quoit-thrower; Perseus, in Werner Medicus, and, as Böttiger explains priaxis, sea-monsters; also a satyr admiring a flute; Minerva; Delphic pentathlete; pancreustas; a Hereules which was in the temple of Pompeius in the Circus Maximus; and also a statue of Apollo which Myron, after Antoninus brought from Ephesus, and Augustus restored to the Ephesians, being warned to do in a dream.

Myron is said to be the first who represented in sculpture Nature in her multiplicity of forms: he represented man and animal with equal success; he almost, says Petronius (Satyricon, c. 88), gave the souls of men and animals to brass. He was, says Pliny, more numerous and various than Polycleitus, but was not so exact in his proportions: he was curious in all corporeal detail, but paid little regard to expression: whether Pliny means this or not by the words 'ipse tamen corporum teneus curiosis, animal sensum non expressisse,' is a characteristic disputed at some length. In the ville de Bucchessi the villa was excellent in representing animals, a quality indicating a strong love of the variety of forms. Myron seems to have adhered in the head and face to the earlier type, as rendered splendidly by Phidias, for he has a round form, and a formal manner of the earlier artists, which he much more probably did by taste than from any want of perception, as Pliny seems to imply.

From an observation of Pliny’s, Winckelmann placed Myron back to the time of Anacreon and Erinnia: Pliny supposed that an epigram of Erinnia spoke of a monument to a grasshopper and a boar by Myron; this epigram is in the Greek Anthology, and, as Pliny asserts, was surpassed by the One nor Myron, there spoken of, says Silius, its virgin whose charms were sometimes fatal to her rivals. Myron executed many works besides those mentioned by Pliny, though some of them were destroyed by fire. It is recorded that in the temple of the portico of the temple of Apollo on the Palantine Mount, and a statue of Hercules is mentioned by Cicero as one of the works plundered by Verres. A statue of Apollo also, with the name of Myron, was on the thigh in silver letters, was plundered from Verres from the temple of Eseulaps at Agrigentum, where it had been consecrated by Publius Seio: Pausanias mentions the Perseus killing Medusa. A great work by Myron was a group in the shape of the quoit. At Sto. Stefano a winged victor among the buculae, one on each side, of which the figures were colossal: it was removed to Rome by M. Antonius, but the Minerva and Hercules were restored to their place again by Augustus; the Jupiter of Bethune place was a statue of Jupiter, which Pausanias, who says, after his Erechtheus, was Myron’s best work at Athens. The Athletes by Myron must have been very numerous, as he was particularly distinguished for works of the kind. He is mentioned several times in Pausanias and other ancient authors; as Sallus, a celebrated Lacedemonian runner; two of Lycius, a Lacedemonian charioteer, at Olympia; Tunnanthes of Cleone, a pancentaist; Philipius of Tallene, a juvenile pupil; and one supposed to be Chionis of Lacedaemon, also an Olympic victor, but denied by Pausanias to be Chionis (vi. 13).

All the above works were executed in bronze of Delos; Polycleitus used the Eginina bronze. But Myron was also a sculptor in marble, a carver in wood, and an engraver of metals. Pliny mentions a celebrated marble statue of a drunken old woman, by Smyrna, by Myron; and Pausanias describes by him a single-bodied Erestes with one head, in wood, which he saw on the island of Eginina: she was the chief divinity of the Eginetans according to Pausanias (ii. 30).

The most celebrated of all Myron’s works was his Cow, lowing, and according to some cackling a calf; there are not less than thirty-six epigrams on this work in the Greek Anthology.

No human figure has attracted so much notice, and doubtless more of the admiration this work excited was owing to the position of its setting up on the Acropolis of Athens than to the beauty of the figure itself. The most celebrated of the horse’s heads which Myron produced were certainly rare, and this Cow may have been the first good work of its class that was set up at Athens: the horses of Phidias were more beast-rilievi placed under a colonnade, and, having the heads of an empress, showed the little effect compared with an isolated bronze, perhaps gilded, figure of the natural size, and fixed upon a marble pedestal in

in the centre of a public place. So according to Cicero it still stood in his time, though it was removed before Pausanias visited Athens, for he did not see it: in the time of Procopius it was in the temple of Peace at Rome. Ausonius wrote the following beautiful description of this work:

Buncha sum, omne grattarum facta Myronis

Succusatque me profana, sed gentium,

Sic viribus et viris profana nomina mortis:

Nec virilis eterna sine mora petit.

Myron’s head he supposes to have been made by

Inter pennis me numerum solit.

(Recipe 5.)

The same idea is still more happily expressed in an old Greek epigram, incorrectly attributed to Anacreon; the following English version of it is from an old translation of Anacreon printed by Dibdin, and is attributed to Fawkes:—

This heifer is not, but swelling years

Hardened the life to what it now appears;

Myron unjustly that honor claim’d.

But Nature has prevented him in fame.

Sonntag has collected all the numerous epigrams on this work of art. The Discobolus by Myron was one of the most celebrated works of ancient art: the original was in bronze, but there are still several antient copies of it in marble, though not one entire: one in the Campidoglio, one in the Vatican, and a third was in the Villa Massimi at Rome; that in the British Museum was in the villa of the Massimi in Rome, and was acquired from them in 1791, and passed into the possession of Mr. Townley through the hands of Mr. Jenkins, a well-known dealer in works of art of that time. Some other trunks of antient statues, which have since been observed, are supposed to be as perfect and as near to the original as the imitations of this work of Myron. The Townley copy according to some critics has been incorrectly restored, and the hand is said not to belong to it. In Lucian’s description of the Discobolus of Myron the head is noticed as being thin and looking back, as it does in some other of the reputed copies of this celebrated work. It must be observed however that there is no proof whatever that any of these marbles are copies from the celebrated Myron. The Discobolus, as it leaves us, is a work of great beauty.

The squat or thigh-throw being turned to the front, or the slow throw—this is the sort of figure, which Phæo interprets by the figure in which he receives it, and which Pliny calls the brewer or the ‘girl or boy who holds the quoit:’ implying that the thrower was not yet in action, having only assumed his position, turned his head back, and extended his hand to receive the quoit from the other hand; the quoit is thrown to him by the attitude of the Discobolus, not expressed. The Townley marble is however throwing the quoit, both knees are bent, and the toes of the left foot, on which the figure partly rests, are put forward, while the right foot is placed either at an angle of forty-five degrees, or nearer to the horse’s head, and the Townley marble is already giving the impetus to his throw. Barry preferred the forward direction of the head, as in this statue, to the turn spoken of by Lucian and seen in other statues of this subject, as much more consistent with the necessary impetus of the throw: he says—‘The position of the head, hanging down in the same direction as the body, is very remarkable in Mr. Townley’s figure, as it is a deviation from the original of Myron, as described by Lucian, and consequently from the Massimi copy, which corresponds perfectly with that description. In all other respects these figures agree, and this deviation appears to have been not unwisely made, as in this way all ambiguity in the intention of the figure, by the direction of the eyes (which are not wanting in the action), is ingeniously avoided; and in finishing the action, at least an equal acceleration of impetus is produced by the head shooting upwards and forward, along with the other extremities.’

Myron had a son Lykos who was likewise a sculptor. He is men­tioned by Pliny, and Pausanias (i. 28) says he saw in the Acropolis at Athens a bronze boy holding a laver, by Lykos, the son of Myron. The Attic Medusa, instead of Averô in this passage): Pliny calls Lykos the pupil of Myron.

[Pliny, N. H. 36. 19; 36. 5; 41. 1; Catullus, Cat. 143; 145. 1; 147. 1; 148. 1; 150. 1; Seneca, Epist. 101, 119; Winckelmann, Werke, vol. i.; Böttiger, Allgemeine Urheber-
MYR, a genus of plants belonging to the natural order Umbelliferae, and to the tribe Umbellifae. It has an ample calyx; obcordate petals, with an infixed point; the fruit not beaked; the carpel covered with a double membrane, the outer membrane with elevated keeled ridges hollow within, the inner one close to the seed, no vitre. The species have leaves three times decomposed, the leaflets pinnatifid; the involucre wanting; the involucels of many lanceolate ciliated leaves, the central flowers of the umbel staminifereous; the petals white.

M. odorata, Sweet Cistley, or Great Chervil, has the leaves downy beneath, the leaflets of the partial involucres lanceolate acuminate. This plant has a stem 3 or 2 feet high, round, leafy, and hollow. It is a native of Middle and South Europe and Asia, from Spain to Asia Minor, also of Germany, Switzerland, Austria, the South of France, and the North of Italy. In Great Britain it is found in pastures and hilly districts. This plant was formerly much used in medicine. It yields a volatile oil, which has a pleasant odour. The young leaves used in salads, the roots boiled or eaten cold, or in tarts or in a variety of sauces. In Germany the seeds were added to soups, and in the North of England they are employed for polishing and perfuming old oak floors. M. officinalis is the species, and it is a native of Spain. Both species may be grown in any common garden soil, and propagated by seeds or division of the roots.

(Myrtus communis, Common Myrtle, has solitary 1-flowered pedicels about the length of the leaves, bearing 2 linear bracteoles under the flowers; the calyx 5-lobed; the leaves ovate, lanceolate, or linear. This beautiful plant is a native of the south of Europe; it is found wild in France about Mar-
sellès, and extends from that city along the sea-coast to Genoa, and throughout Italy. In these districts it forms thickets, and rarely grows without the spray of the sea. This plant has been in all ages a great favourite in Europe. It was called by the Greeks μύρος. Μυρίγιον is the name under which Hippocrates refers to this plant (Horm, Med, i, 560). Theophrastus also uses this word and μυρίγιον and μυρίς, in speaking of the myrtle. The Romans knew this plant by the name of 'Myrtus' (Plin. 12-13). This name has been adopted in most European languages: it is Myro in Italian and Spanish; Myrte in German; Myrte in Danish; Myrtens in Swedish; Mirté in French; Mürta in Portuguese.

The leaves of the myrtle, like the whole plant, contain a volatile oil which possesses medicinal properties, and that was used as stimulants by the ancients. The buds and berries of this plant also contain volatile oil, and were used by the ancients as a spice, and are at this day, in Tuscany, employed as a substitute for pepper. The Tuscans also prepare a kind of wine from the myrtle called myrtidum. The berries are used at the present day in Greece as a remedy in the diarrhoea of little children. The mode of adapting them is unknown; they may be cast of the myrtle have an agreeable scent, and when distilled they form the perfume sold in France under the name of 'Eau d’Ange.' In addition to a volatile oil the myrtle contains a quantity of a wine which on some is astrigent action, and have been used for this purpose. In Greece, Italy, and the South of France, the bark is used for tanning.

The myrtle is a half-hardy plant in this climate, although many individuals have lived and borne our winters for above a hundred years. The myrtle appears to have been introduced into England in the sixteenth century. There are at the present time many fine myrtle-trees in Great Britain and Ireland. At Corham Hall, in Kent, there are several specimens 50 feet high. In the Isle of Wight it forms the hedges of many gardens, but however be be not to that, many have been cultivated by protection during the winter. Several varieties of the Myrtus communis are found in gardens, of which the following, from Don's 'Gardener's Dictionary,' may be regarded as the principal.

M. alenocarpa (D. C. Prod. iii. p. 239), fruit blackish. This variety of myrtle is frequent in the south of the west, and in gardens, where there are varieties of it with double flowers and various other improvement, often cultivated by protection during the winter. Several varieties of the Myrtus communis are found in gardens, of which the following, from Don's 'Gardener's Dictionary,' may be regarded as the principal.

Var. a. Romana (Mill. p. t. 184, p. 1), leaves ovate; pedicels longer. The common broad-leaved or Roman myrtle. It is sometimes called flowering myrtle, because it flowers more freely in England than any other variety.

Var. c. Italica (Mill. Dict.), leaves ovate-lanceolate, acuminate. The orange-leaved myrtle.

Var. d. Etruscica (Mill. Dict.), leaves lanceolate, acuminate. The broad-leaved Dutch myrtle. Leaves crowded, dark green. The double flowering myrtle appears to be of this variety.

Var. e. Bellica (Mill. Dict.), leaves lanceolate, acuminate. The broad-leaved Dutch myrtle. Leaves crowded, dark green. The double flowering myrtle appears to be of this variety.

Var. f. mononthera (Lin. Dict.), leaves linear, lanceolate, acuminate. M. minima (Mill.), rosemary or thyme-leaved myrtle.

M. monantha (D. C. Prod. iii. p. 239). Fruit white. Native of Greece and the Balearic Isles. The fruit of this is rather large, edible, with a grateful taste and smell.

The above varieties are constant; but there are others in the garden which are more variable. It will suffice to give the names of a few of these.

1. Gold-striped broad-leaved myrtle.
2. Broad-leaved Jew's myrtle. This variety frequently has its leaves in threes, on which account it is said to hold in esteem among the Jews in their religious ceremonies.
4. Silver-striped Italian myrtle.
5. Striped box-leaved myrtle.
7. Var. a. etaminiferous. This myrtle appears to be only a variety of this.
8. Cockscough, or bird's nest myrtle.

About forty other species of myrtle besides those of the old genus Myrtus now referred to the genera Myrica, Symphytum, Eugenia, &c., have been described. None of them yield products used in arts or medicine, and only a few of them have been cultivated.

M. tomontea is a native of Cochinchina. It is a handsome shrub, and has been found to grow well against walls in the south of England.

M. nummularia is a creeping species found at the Straits of Magellan, and M. nummularia, a native of the colder parts of Peru, would probably be found to be half-hardy in this climate.

The species of the genus Myrtus grow well in sandy loam and peat; and cuttings readily strike in sand or peat. (Don, Gardener's Dictionary; London, Arborum Brit. ; Friaa, Synopsis Flora Classicca, in; Burnett, Outlines of Botany: Lindley, Flora Medic.)
of royal and distinguished personages, some of which are at
Hampton Court; and he was in great favour until about 1632,
when he was so much discontented at the favour shown by
the king to Vandyck, that he solicited Charles for leave to retire
to his own country, but the king, learning the cause of his
dissatisfaction, entrusted him to remain, and told him that he
should have work enough both for him and Vandyck. Mytens
remained, but apparently for a short time only, as none of his
works in England bear a date subsequent to the arrival of
Vandyck. The two rivals however parted apparently on
good terms, for Vandyck painted the portrait of Mytens, and
it is engraved in the collection of Vandyck's portraits, by
Fontus. Mytens returned to the Hague, and was still living
there in 1656, when he painted a portion of the ceiling of
the town-house of that place. His style was bold, firm, and
natural, his colouring mellow and harmonious, and his pictures
are frequently enriched by warm landscape backgrounds.
There are many of his portraits at Hampton Court, of which
the full-length of James, first Marquis of Hamilton, is an
excellent picture: there are here also Prince Rupert when a
boy, and the dwarf Sir Jeffrey Hudson, who, when seven
years old, was served up in a pie at Burleigh, at an enter-
tainment given by the Duke of Buckingham to Charles I.
and Henrietta, and was presented by the duchess to the queen,
who kept him as her dwarf. Hudson was then only eighteen
inches high; he grew, after he was thirty, to the height of
three feet nine inches. Mytens introduced this dwarf in a
large portrait of Charles and his queen, which was in the
possession of the Earl of Dunmore. Sir Jeffrey died a pris-
soner in the Gate-house, Westminster, in 1692, aged sixty-
three: he was imprisoned upon suspicion of being concerned
in the Popish Plot.

A more celebrated painter of the period was Hollar, who
was a pupil of Mortier, an artist of considerable note who
lived in the reign of Charles II. He was a man of great
ability, and is said to have been the inventor of the process
of engraving upon copper plates, which was afterwards
perfected by Merian. Hollar was also a great etcher, and
his works are still highly esteemed for their beauty and
accuracy. He is especially noted for his prints of the
ruins of ancient buildings, and of the natural history of
the birds and beasts of the country. His drawings are
also very fine, and are much prized by collectors.

The other great artist of the period was Willem van de
Veldt, who was born in about 1610, and died in 1691. He
was a pupil of Rembrandt, and was celebrated for his
Portraits, landscapes, and historical paintings. He was
also a great etcher, and his engravings are very fine and
beautiful. He is especially noted for his portraits of
the great men of his time, and his works are much prized
by collectors.

The following are some of the artists who were
active in the period:

1. Pierre Martens (1623-1699), a painter and
etcher, who was born in Brussels and died in
London. He was a pupil of Rembrandt, and
was celebrated for his landscapes and portra-
ts. His works are still highly esteemed for
their beauty and accuracy.

2. Willem van de Velde the Elder (1633-1707), a
painter and etcher, who was born in
Amsterdam and died in London. He was
celebrated for his seascapes and marines,
and his works are still highly esteemed
for their beauty and accuracy.

3. Jacob van Ruisdael (1628-1682), a painter
and etcher, who was born in Amsterdam
and died in Amsterdam. He was celebrated
for his landscapes and seascapes, and
his works are still highly esteemed
for their beauty and accuracy.

4. Jan Steen (1626-1679), a painter and
etcher, who was born in Dordrecht and
died in Dordrecht. He was celebrated
for his peasant scenes and still-lives,
and his works are still highly esteemed
for their beauty and accuracy.

5. Gerrit Dou (1613-1675), a painter and
etcher, who was born in Amsterdam and
died in Amsterdam. He was celebrated
for his still-lives and intimate scenes,
and his works are still highly esteemed
for their beauty and accuracy.

6. Aelbert Cuyp (1620-1691), a painter and
etcher, who was born in Dordrecht and
died in Dordrecht. He was celebrated
for his seascapes and marines, and
his works are still highly esteemed
for their beauty and accuracy.

7. Gerard van Honthorst (1590-1656), a
painter and etcher, who was born in
the Netherlands and died in Florence.
He was celebrated for his portraits and
portraiture, and his works are still highly
esteemed for their beauty and accuracy.

The following are some of the artists who were
active in the period:

1. George Vertue (1684-1756), a painter and
etcher, who was born in London and
lived in London. He was a pupil of
Watteau, and was celebrated for his
Portraits and landscapes, and his
works are still highly esteemed
for their beauty and accuracy.

2. John Sellars (1695-1766), a painter and
etcher, who was born in London and
lived in London. He was a pupil of
Watteau, and was celebrated for his
Portraits and landscapes, and his
works are still highly esteemed
for their beauty and accuracy.

3. John Coney (1695-1751), a painter and
etcher, who was born in London and
lived in London. He was a pupil of
Watteau, and was celebrated for his
Portraits and landscapes, and his
works are still highly esteemed
for their beauty and accuracy.

4. John Lewis (1695-1751), a painter and
etcher, who was born in London and
lived in London. He was a pupil of
Watteau, and was celebrated for his
Portraits and landscapes, and his
works are still highly esteemed
for their beauty and accuracy.

5. John Raphael (1695-1751), a painter and
etcher, who was born in London and
lived in London. He was a pupil of
Watteau, and was celebrated for his
Portraits and landscapes, and his
works are still highly esteemed
for their beauty and accuracy.

6. John Smibert (1687-1751), a painter and
etcher, who was born in London and
lived in London. He was a pupil of
Watteau, and was celebrated for his
Portraits and landscapes, and his
works are still highly esteemed
for their beauty and accuracy.

7. John Board (1695-1751), a painter and
etcher, who was born in London and
lived in London. He was a pupil of
Watteau, and was celebrated for his
Portraits and landscapes, and his
works are still highly esteemed
for their beauty and accuracy.
NAGPOOR, a district formerly included in the province of Berar, in Hindustan, but now in the adjoining province of Gandwa, of which the city of Nagpoor is the capital.

Ellipsoor is the capital of Berar. The palace and seat of government of the British is at Nagpoor, and hence it has as frequently styled the raja of Nagpoor as the raja of Berar. The state of Berar, or Nagpoor, is one of those over which the British authorities hold full political sway, with right of intervention, in the events of the state, and they have a political agent resident at Nagpoor. The British government is bound by treaty to protect the raja of Nagpoor, and he is bound to pay to the British an annual subsidy of 80,000/., to maintain five regiments of infantry and four regiments of cavalry, and a contingent force of 1000 cavalry to co-operate with the British in case of war. The area of the state is about 64,000 square miles, the population about 2,650,000, and the estimated revenue 350,000/.

The portion of Berar which lies to the west of the river Wudah is included in the territory of the Nizam of Hyderabad and the title of raja of Nagpoor is consequently now perhaps a more appropriate title than raja of Berar, a large portion of the territory of Berar having been transferred to the Nizam after the termination of the Mahrrata war

(Ellichpoor) 'The East India Gazetteer': Malcolm's Central India; Appendix to Report on East India Produce."

NAIL. The use of nails being illustrated under Joints, P.C.S., p. 121, it will be sufficient here to notice the various modes by which they are manufactured.

Until a comparatively recent period almost every kind of nail was produced by hand-labour; each nail, however minute, was separately forged from a thin rod of iron, a process which is still followed in the production of what are technically known as wrong nail; and as nails so formed possess certain advantages, for particular kinds of work, over those formed either by casting, or by cutting or stamping out of rolled sheet metal, there is no reason to anticipate the total abandonment of this process, notwithstanding the continual improvement of nail-making machinery.

The making of wrought nails, which retains, in most places, the character of a domestic manufacture, forms the employment of a peculiar class of blacksmiths called nailors, who are very frequently assisted by the female members of their families. The nailor receives his iron in the form of narrow square rods, of various sizes, according to the kind of nail to be forged from them. Putting the ends of three or four such rods into the forge, at one, the nailor commences his work by hammering down the rod, which is now forged, on its end upon a small but very firmly bedded steel anvil to a tapering point. The pointed end is then cut off to the proper length, which is adjusted by a gauge, by laying it across a flat iron, and giving the blade with the head of the hammer. In some cases, as in making the kind of nail used for fixing horsehoes, this operation completes the nail; but in most cases a subsequent process is necessary to form the head.

For this purpose the red hot slab just quenched is laid on the nail-rod which is taken up and dropped, point downwards, into one of the holes of an instrument called a bore, which is a piece of iron, ten or twelve inches long, with a perforated knob of steel at each end. The holes of this instrument are made to fit the upper or thicker part of the nail, and so counterbore at their upper ends as to form a kind of mould for the head of the nail. When dropped into one of these holes, a few well-directed strokes of the hammer upon the thick projecting end of the spike or nail conveyed it into a head of any required shape. In making small nails it is sometimes practicable to forge and cut off two lengths from the nail-rod, but where this is not the case the nailor is enabled to proceed with his work without interruption by the convenient plan of having several rods in the forge, once cut, to be worked upon simultaneously. Bartow describes the manufacture of nails in his account of various processes of forging and cutting; and the whole subject is referred to his hand. In many cases, for the sake of economy, two or three nailors work at one hearth, using the same fire and the same bellows in turn; and Holland, who, in his treatise on 'The Mechanic's Encyclopedia,' vol. i. pp. 192-218, gives much curious information on the nail manufacture, describes a very simple, cheap, and convenient circular forge, patented in 1824 by Mr. Spencer, of Belper, around which five or six persons may work at the same time, and which possesses the further advantages of allowing the use of pure wood charcoal, by which the quality of the iron hosted is improved, of having no back, and of having a grating to keep them dry by the accumulation of clinkers. Though adapted also for some other purposes, this forge is especially intended for the use of nailors. The hammer used by nailors is larger or smaller, according to the size of the nails to be formed, in form, according to Hall's description, is 'the frustum of a cone, the smaller end being the base, which, instead of forming a horizontal plane, as in the case of an ordinary round hammer, is inclined or sloped considerably towards the handle. 'The degree of this obliquity, the weight of the hammer head, the size and shape of the handle,' &c., he adds, are matters of nice consideration, one nailor being rarely able to work comfortably with another man's hammer; and hence he observes, 'they are somewhat given to tramping from place to place, each workman generally carries with him a favourite hammer, which, like the famed mallet of Thor, is both the symbol and the agent of the owner's power. Of the astonishing dexterity of some of this class of operatives Holland quotes a remarkable illustration from the 'Mechanics' Magazine,' Sept. 12, 1778, in the case of the silur who undertook and accomplished the task of making, in each of two successive weeks, seventeen thousand (1200 to a thousand of 20 lbs.) of double flooring nails; in performing which task, as each nail required about twenty-five strokes of the hammer, which weighs about two pounds, he made, including the cutting up of the nail-rots into convenient lengths, and re-uniting them when they became too short, no less than 1,085,656 strokes, and moved to and from the fire at which the nails were heated 42,836 times. This task is, Holland states, allowed to have been as much as three ordinary men could perform without difficulty.

For some purposes nails formed by the much cheaper process of casting have been long used instead of those wrought in the manner above described. Common cast nails are, however, so clumsy and so brittle that they can only be used for a few coarse purposes, as in plasterer's work, and in the nailing up of fruit-trees. By the introduction of great improvements in the manufacture, however, a very useful kind of cast nail, of an exceedingly pure material, called malleable cast iron, has been successfully introduced for certain descriptions of woodwork. Nails of this kind are very neat and regular in their appearance, being cast with great accuracy; and they are used to such an extent that they will bear far more bending than ordinary wrought-iron without injury. This extraordinary degree of tenacity is, however, obtained at the expense of rigidity, such nails being often nearly as soft as copper, and therefore quite unsuitable for use in hard woods.

The comparatively high price of wrought nails, owing to the great amount of manual labour required in making them, and the insufficiency of cast nails as a substitute for them, has led to the introduction of many highly ingenious machines for forming nails by cutting, stamping, or compression, out of plates or rods of rolled-iron, and with such success that, for two ordinary purposes of the carpenter and joiner, cut nails, varying in size from the smallest tack or brad up to spikes of six inches or more in length, we almost superseded those wrought by hand. According to Bartow's 'Treatise on Machinery and Manufactures,' in 'Encyclopedia Metropolitana,' the earliest machine for nail-making was contrived by Mr. French, of Wimborne, Staffordshire, in 1790, in which machine, instead of making nails by the hammer, but labour was saved by working hammer by water-power, so that women and children might perform work which would otherwise have required much muscular exertion on the part of the nailor. Bartow describes a machine in which the various processes of rolling, pressing, stamping and cutting are introduced; but for the details of such machinery we must refer to his work, that of Holland, above quoted, Dr. Ure's 'Dictionary of Arts and Manufactures,' and Heber's 'Engineer's and Mechanic's Encyclopedia.' Dr. Ure attributes the invention of cut nails to the citizens of the United States, observing that, according to a report by the secretary of the state of Massa...
chamets, so long since as the year 1810 they possessed a machine which performed the cutting and heading at one stroke, with sufficient rapidity to turn out 100 nails per minute. In the process, the most commonly followed nails are cut from sheet-iron of suitable thickness, which is first reduced, by cutting transversely, into strips or ribbons, to the dimensions of the nails required. These strips are then applied to a machine in which a chisel-shaped cutter descends with sufficient force to cut off from the end of the strip, at each downward stroke, a narrow piece sufficient to form a blade. As the nails are required to have a tapering form, the cutter must be so fixed as to form a slightly oblique angle to the direction in which the strip is pushed into the machine, and this obliquity must be reversed or renewed with each stroke, by the means adopted in comb-cutting machinery. [Com. F. C. S., p. 298.]

If the nails are to be of any of the kinds to which the term nail is specifically applied, as distinguished from brad, the edge of the cutter is simply reversed, so as to reduce the strip of iron into long wedge-shaped pieces, and the pieces thus separated are subsequently headed by pressure or stamping, so as to form finished nails; but if the nails are to be of the kind, the action of the cutters can be so modified as to produce cuts alternately at right and oblique angles with the edges of the strip. Nails of this kind need no subsequent heading, but are completed by the action of the cutter. The action of the cutter is produced by laying together side by side, heads and points alternately, a number of cut nails or brads, when it is found that they readily come to compose a regular line. In some machines the cutters do not vibrate or vary their position, but the strip of iron is turned between each cut, so as to produce the same effect. Brads are frequently cut out of hoop-iron instead of transverse strips of sheet-iron, as above described; but the practice is much to be deprecated, although the brads so formed have a rather neater appearance than others; for it is evident that, in the operation of rolling, the fibers of the iron are laid longitudinally in the strip, they must lie across instead of along the nails cut transversely from it, thereby rendering them very weak and brittle. The advantage derived from the superior squareness of cut nails, as compared with wrought, is alluded to under JOINERY, p. 121; and another peculiarity of considerable importance is that, as such nails are usually tapered in one direction only, their points are somewhat chisel-shaped, and, though sharp, as broad as the body of the nail. If, therefore, such a nail be placed with its chisel-shaped point across the grain of a piece of soft wood, it may be driven in without biting, and without the risk of splitting, which would arise if the nail were, as most wrought-nails are, tapered on every side.

In some of the coarser operations of carpentry nails are secured by clenching, or bending down their points with the hammer, instead of being driven completely through wood when they are intended to hold together. Hebert notices a very neat and secure substitute for this rather clumsy expedient, which consists in placing on the projecting end of a nail a little strip of iron, called a brad, a small nut, and then clenching or riveting the end of the nail down upon it. He states that this mode of fastening appears, though without reason, to be almost entirely confined to boat-building.

Nails of iron with ornamental brass heads are much used for hanging pictures upon, and for other purposes in which the heads of ordinary nails would be unsightly; and nails wholly formed of brass, or composed of silver and brass, are used in ship-building, and for a few other purposes. For the mode of coating small iron nails or tacks with tin, for use in cases where iron tacks are injurious, see TINNING, p. 482.

NAPKICHYAN. [Extrait du Biog. C. F. C. P. C.]

NANTEUIL, ROBERT, a celebrated French engraver and draftsman, was born at Rheims, in 1630, and was the pupil of his brother-in-law, N. Regemaison. He engraved chiefly portraits, in which class he is one of the most distinguished engravers, though he generally engraved the head only, without accessories; but he frequently executed them of the whole body. His engravings are very lifelike, and in a very able manner; but as he used these chiefly to engrave from, few of them have been preserved. He engraved in line and in stipple, and generally combined both styles, stipple and line, which he used to express color to a considerable degree in his prints. Nanteuil died in 1678, and though he lived to the age of forty-eight only, he has engraved nearly 300 plates, almost exclusively portraits, and comprising many of the princes of Europe, and most of the celebrated men of France during the reign of Louis XIV., of whom he was a pupil in the school of the Carpentras period of his life. His master-pieces are J. B. van Steenbergen, after Duchatel, known as l'advocat de Hollande, 1688; M. de Pomponne, after Le Brun; F. M. la Mothe le Vayer, after J. R. C. de Montfaucon.

(Wattelet et Levensque, Dictionnaire des Arts, &c.; Huber, Manuel des Amateurs, &c.)

NARTOSTACHYS, a genus of plants belonging to the natural order Valerianacae. The limb of the calyx is 4-parted; the lobes ovate, oblong, acute, leafy, somewhat toothed and permanent. The corolla is regular, calcarate, obtusely 5-lobed and bearded in the throat. There are four stamens, which are similar to the pairs of the corolla, and are herbs with sweet-scented perennial roots, which are beset with erect filices at the neck.

N. satanana is a dwarf herbaceous plant with a long hairy tap-root. The stems are perennial, very short, and simply divided into a number of shaggy, scaly crowns, from which the leaves are produced. The branches erect, downy, and a few inches high. Leaves obovate, lanceolate, 6-ribbed, downy; those at base acute, the upper ones obtuse. The flowers are of a pale pink colour, clustered in the axils of the upper leaves, which form a kind of involucre for them. It is native of Nepal, on the Himalaya mountains, and in Delhi, Bengal, and Assam, and is esteemed not only as a perfume, but as a stimulant medicine. Oriental writers give it as a remedy for tears, and for the palpitation of the heart. It seems to be really valuable in cases of epilepsy and hysteria.

N. grandiflora has a glabrous stem, oblong glabrous leaves, with solitary terminal flowers. The capsule is downy, and the lobes of the calyx evidently dentilicated. It is native of Nepal and Kumaon.

These plants should be grown in pots, in a mixture of loam, peat, and sand, and placed among other Alpine plants. They may be propagated by dividing the root, or by seeds.

(Don, Gardener's Dictionary; Lindley, Flora Medica.)

NARTHECIA, a genus of plants belonging to the natural order Juncaceae. The perianth is partly coloured, of 6-linear lanceolate persistent leaves. The filaments are woolly, and the style undivided. It has a simple obtuse stigma. The capsule pyramidal, 3-celled and 5-valved. The placenta extends only a short distance up the inner edge of the dissection. The seeds have a long filiform appendage at each end.

N. osafrutum, the only British species, has lance-shaped leaves, pedicels with one bract at the base, and another above the middle. The perianth is longer than the stamens, and considerably shorter than the capsule. The flowers are bright yellow. This species is distinguished especially by its seeds.

(Babington, Manual of British Botany.)

NASIREANS. [NAZAIRENS, P. C.]

NASIMITH, DAVID, was born in Glasgow, on the 21st of March, 1801, and in 1830 was assembling a very valuable collection of books with a view to his entering upon a course of college study at the University of that city. Finding, however, that he was averse to the study of the learned languages, this intention was abandoned, and he was early placed in a mercantile establishment. In 1818 he commenced the efforts by which he subsequently became so eminently distinguished, by taking an active part in the formation of a Youths' Bible Association at Glasgow, of which he became the secretary; and at the age of sixteen he made a public profession of religion by joining the church in Nile-Street, under the pastoral charge of the late Rev. Greville Ewing. He shortly afterwards made great exertions to prepare himself for the Christian ministry; but as his friends did not encourage the attempt, he returned to secular employment, but engaged with great zeal in Sunday-school teaching, in the establishment of adult-schools, the religious instruction of prisoners, and other philanthropic efforts. In the autumn of 1821 an event occurred which, by affording enlarged scope for his benevolent desires for the religious and moral improvement of the people, led to the fuller development of a character which, for distinguished devotedness, has been rarely equalled. 'The conductors of the various religious and benevolent societies in Glasgow,' observes Nasmith's biographer, 'had with a view to their objects, a large and commodious edifice, which was divided into rooms and offices, suitable to their respective objects; and the completion of their plan required the services
of an active secretary, who should be common to them all. In answer to an advertisement for such an officer, Nasmith offered his services in the first year of the institution, at a salary of sixty pounds, though the interests of twenty-three societies thus doved upon him. In this office he was brought into frequent communication with committees composed of ministers and lay members of the Established Church, and so gained the personal esteem of many of the most eminent men of Glasgow; and the remarkable course of mental training thus afforded had the effect of fitting him for the singular career he was subsequently to pursue. To this biographer attributes the 'free, easy, and noble air' by which he was distinguished in after life, and to which he appears to have been largely indebted for his influence over men who were his inferiors in talent and station, and who were inclined to regard his projects with prejudice and distrust. 'Even on the first interview,' observes Dr. Campbell in the 'Memoirs,' 'this article is chiefly based, no one could escape the impression that he was a man of extraordinary integrity and sagacity, piety and benevolence.'

Mr. Nasmith, observes Mr. Ashbury, 'was a man of consummate ability and tact in the formation of societies.' 

'It was,' he remarks, 'his great talent; and it was manifested in his power of directing a committee without assumption on his own part, patiently attending to the various opinions of members of the committee, the account of his deserts, wise, and gently intimating his own judgment, which, being founded on great experience, was generally adopted.' In this office he also, to return to Dr. Campbell's account, 'obtained a very distinct perception of the difficulty involved in leaving a province to such a character,' and in the latter part of 1828 discovered its wants; he saw directly before him the amount and character of the agency provided for the supply of those wants; and hence he ascertained how much of those wants remained still unsupplied.'

While faithfully discharging his onerous duties in connection with the existing philanthropic societies of Glasgow, Nasmith applied himself also to the formation of such new associations as seemed to him most needed. He was the moral and religious welfare of that and other populous places. Young Men's Societies, or associations for promoting the religious interests of young men, for protecting them from the temptations incident to a residence in large towns, and for directing their united energies into channels of benevolent exertion, occupied them, as in his later years, a large share of his attention; and in a letter upon the subject addressed by him to Professor Buchanan in February, 1828, he states that he had been the means of forming about seventy such societies, in the United Kingdom, France, and America, since the close of the year 1828. A still more important project, and one which has proved far more extensively successful in practice, was the formation of city and town missions, or societies for carrying religious instruction, by means of lay agents wholly devoted to the spread of the gospel, into all the hovels and tenements of the city, into the very haunts of vice and dissipation. Attempts had been previously made in a few instances, and on a small scale, to accomplish this object; but the difficulties of the task, especial the want of a sufficient number of intelligent and zealous associations of the Christian Church, had impeded their success. In spite of such difficulties, Nasmith succeeded in establishing, at the commencement of 1826, the 'Glasgow City Mission,' which, though commenced by the congregation to which he belonged, was constituted on so catholic a footing that, before the end of its first year, eight evangelical denominations of Christians were united in its management, and eight missionaries were employed. The success of this society encouraged Nasmith to print and circulate widely, not only in the British Islands and America, but also in France and other parts of the continent of Europe, a report of the operations and results of the Christian Church, on the mission of which he impelled his success. In the same year Nasmith married Miss Hartridge, a native of Kent, who was then residing in Glasgow, and who became a most valuable coadjutor in his benevolent designs. In 1828, his health being impaired by the arduous duties of his office, Nasmith resigned his connection with the Institution House at Glasgow, and from that time until his death he devoted himself wholly to the exercise of the duties of an active missionary, travelling from place to place to promote the establishment of city and town missions, young men's societies, and other kindred associations. The self-denial and moral courage with which Nasmith pursued his object, the ordinarily character, since it involved the relinquishment of any settled means of obtaining a livelihood, and of all prospect of attaining a station to which his talents entitled him; while he had no property on which to rely even for travelling expenses, nor any society on which to fall back for support. His first benevolent mission was to a poor village, a few miles from the prosperous city mission. Having subsequently visited London, and his wife's family in Kent, he returned to Glasgow, and thence again to Dublin, where he formed a society for promoting the establishment of the mission in the metropolis of Ireland, and at the same time, at the request of some friends who were opposed to its objects, he went to England, and from thence proceeded to Scotland, and in a few weeks performed the same work in Edinburgh. Having visited Ireland and Scotland, and having been in the north of England for some weeks, he returned to Glasgow, and prepared for a voyage to the United States on the same benevolent errand. Arriving at New York in September, 1830, he formed a city mission, and soon after set out for Philadelphia, which he reached in a few weeks, he found the Americans equally indebted to England and Scotland as to Scotchmen and dissenters. Here, during the three years and seven months over which the expenditure was spread, the sums received by him from friends who took an interest in his efforts amounted only to 4394. 10s. 9d., and the proportion was increased by the means of many other benevolent societies. Nasmith, who was of too catholic a spirit to care to what section of the Christian Church his fellow-labourers belonged, so that they were real Christians and united in the same object, he preferred to leave the decision to the conscience of each man, and who, indeed, in answer to inquiries respecting himself, would say 'I am a Christian, or I am a Catholic,' neither suffered objections or difficulties or impediments to debar him from his aim, nor to induce him to lessen his moral grandeur by identifying it with sect or party. The London City Mission was therefore commenced in conformity with the design of its founder, but without the aid of any churchmen. Lane, indeed, after a while, finding his fears groundless, heartily united to carry it on. Operations were commenced with only four missionaries, with salaries amounting in the whole to 207l. per annum; but so rapidly and uniformly improved was its constitution that in 1845, at the date of the tenth annual report, the number of missionaries employed was 121, and the expenditure in salaries alone for the preceding year had been 7400l., exclusive of all other expenses incident to the mission. In the same year the number of domiciliary visits, and visits to hospitals, schools, and other places where the poor and ignorant are congregated together, paid by the missionaries amounted to 44,080, of which 39,469 were to the sick and dying. In a large majority of the latter class of visits the agents of the city mission were the only individuals by whom religious instruction and consolation were afforded to these poor wretched sufferers. The distribution of Bibles and religious tracts, the holding of religious services in neglected neighbourhoods, and various other benevolent operations, are also carried on by the missionaries, and the great provision has been made, by the appointment of agents suited to their peculiar necessities, for the spiritual wants of the drivers, and of the numerous Laconians, Germans, and other foreigners in the metropolis. By gaining the confidence of the people, of which Nasmith has been possessed, by the means of the city mission, the missionaries have obtained access, and often with the best results, to the haunts of misery and vice which no other agency has been able to reach. They therefore constitute a kind of moral police, of which Nasmith was the originator, and the documents published monthly in the 'London City Mission Magazine' afford abundant proof. One missionary alone, in Clerkenwell, has, according to the report above quoted, sec-
N A U C L E A, a genus of plants belonging to the natural order Rubiaceae. It has a calyx with an oblong tube and a short truncate or 5-toothed limb. The corolla is funnel-shaped, with a slender tube, a naked throat, and 5 spreading oval oblong lobes. The anthers are inclosed, and always shorter than the lobes of the corolla. The capsules are 2-valved, and the sepalas of the fruit are inappreciably reduced to the base. The seeds numerous, imbricate, winged, fixed to oblong placentae, which are adnate to the dissepiment. The embryo is invested in a fleshy albumen. The leaves are evergreen, entire, and wanting at the base of the head of flowers, but with linear pales among the flowers, which are crowded and sessile. The species are unarmed trees, rarely shrubs, and natives of India and Africa.

1. Cadamba has bracteate branches, petiolar, coriaceous, ovate leaves, triangular stipules, terminal solitary peduncles, usually shorter than the heads, which are globose. The flowers are white and coriaceous, and are protected by the involucral bracts about the size of a small apple. The style is white and exserted. The seeds not winged, the leaves from 5 to 10 inches long.

2. Kudamba is the native name of the tree; it flourishes about Calcutta and Malabar, where it grows to be a very large tree, and is ornamental and very useful from the extensive shade it affords.

3. Porphyrotheca has petiolar obvolute leaves, oval stipules, and terminal solitary peduncles; sometimes the peduncles are in tripicles, when the middle one is the shortest. It is native of the East Indies and all the coast of Coromandel, but chiefly in the mountains of the Philippines. The flowers are light yellow, and globular, about the size of a plum. The wood is of a pale chestnut colour, firm, and close-grained; it is useful for purposes where it can be kept dry, but is not in high estimation.

4. Cordfeolia is prized on account of its wood, which is light and durable where it can be kept dry. It answers well for furniture. There are thirty-seven species of this genus in different parts of the world. Some of them are numbered and figured in the Botanical Register. They do not possess any peculiar qualities which entitle them to particular notice. They are of easy culture. A mixture of loam, sand, and peat is the best soil for them, and they readily take root under a hand-glass in the same kind of soil.

The Naucal Gamba of Hunter (Lithograph Transactions, vol. ix.) is now Uncaria Gamba. (Uncaria, P. C.)

NAUCRATES, a genus of fishes of the mackerel tribe, having fusiform bodies, tails healed at the side, and two free spines before the anal fin. The Naucrates ducers is popularly known as the Pilot Fish, and is remarkable for having a habit of following vessels often for many hundred miles. Mr. Croch, in the 14th volume of the "Linnaean Transactions," has recorded an instance of two individuals of this species which accompanied a ship from the Mediterranean to Plymouth, where they were taken by a net. The Naucrates ducers is about six inches in length, and is remarkable for the beauty of its colour, being of a silver pale blue banded by brown and deep transverse dark blue stripes.

NAUCYLIDES (Naucylides), a Greek sculptor, who was born at Argos, and was in reputation, perhaps, near Ot. 58; he was the son of Mothon and the brother and master of the celebrated sculptor, Polyclitus. He was one of the most important artists between Alcamenes and Praxiteles. Phylly mentions a Mercury, a Discobolus, and a man sacrificing a ram, by him. Paussiut notices six

N A S M I T H, a painter, born in Edinburgh, in the year 1786. He showed an early decided talent in painting, and at the age of seventeen, was an institution of art to his father. In the pursuit of his favourite art left him little opportunity of acquiring other instruction. Early in life he injured his right hand, and learned to use the pencil and brush with his left. At the age of nineteen he went to London, and his productions soon became very popular, obtaining for him the designation of the English Hobbina. It cannot be said however that he had much in common with the great Flemish master, excepting the same love of detail and elegance in his compositions. He has not the same firmness of touch as Hobbina, producing his results by an apparent multiplicity of detail. He improved in the style of his father, and his pictures have less of the spotted

Chalky character, which, from its having been followed by other members of this clever family, is characteristic of what is called the 'Naucrat School.' Notwithstanding a certain air of coarseness, Peter Nasmyth's landscapes are eminently pleasing. Though he often painted Scottish scenes, and his works are perhaps more admired in his native country than elsewhere, only a few of them were ever executed in the English. His style was not sufficiently massive property to represent the wild mountain scenery and striking atmospheric peculiarities of Scotland. Light clouds, sunshine, smooth water, or small pettering brooks, meadows, gentle rising ground, and green trees, are the objects which his style was best calculated to represent. He died in lodgings in South Lambeth, London, on the 17th of August, 1831, during a memorable period of the metropolis, when the contemplation of natural objects—strong in death—he was lifted up in his bed to behold. (The dates and incidents are taken from Memoir in Lit. Gazette, 1831.)

NASUTURTIUM. [Tropaeolum, P. C.]

1. Naucratia is a genus of plants, belonging to the natural order Rubiaceae. It has a calyx with an oblong tube and a short truncate or 5-toothed limb. The corolla is funnel-shaped, with a slender tube, a naked throat, and 5 spreading oval oblong lobes. The anthers are inclosed, and always shorter than the lobes of the corolla. The capsules are 2-valved, and the sepals of the fruit are inappreciably reduced to the base. The seeds numerous, imbricate, winged, fixed to oblong placentae, which are adnate to the dissepiment. The embryo is invested in a fleshy albumen. The leaves are evergreen, entire, and wanting at the base of the head of flowers, but with linear pales among the flowers, which are crowded and sessile. The species are unarmed trees, rarely shrubs, and natives of India and Africa.

2. Cadamba has bracteate branches, petiolar, coriaceous, ovate leaves, triangular stipules, terminal solitary peduncles, usually shorter than the heads, which are globose. The flowers are white and coriaceous, and are protected by the involucral bracts about the size of a small apple. The style is white and exserted. (The dates and incidents are taken from Memoir in Lit. Gazette, 1831.)
other of his works: A Hebe, in ivory and gold, placed near the celebrated chryselephantine statue of Juno at Myron's, by Phidias, in the Temple of Minerva at Athens; and four victors at the Olympic games, one of Eucles at Rhodes, two of Chiron, one of which was at Olympia, the other in the Temple of Peace at Rome, and the fourth of Bacchus, all covered with the leaves of the olive. Krates, a rich man at Athens, was once carried in the chariot of Dionysus to the games, and was allowed the company of the victors, a privilege which was considered a mark of distinction and honor.

(Neator, Catalogus Artificiorum, lib. vi, p. 40; Plutarch, Aristas, 13.)

NEBURJ. [Star, P. C., pp. 449, 450.]

NECTANDRA, a genus of plants belonging to the natural order Lauraceae. It has a 6-parted rotate calyx, deciduous segments, the three outer rather the broadest. There are 9 anthers which are ovate, nearly sessile, with 4 cells, arranged in a curve, and distinct from the tip of the anther, the cells of the interior anthers inverted. The glands are in pairs, globose, sessile at the base of the three interior stamens next their back. The fruit is succulent, more or less immersed in the tube of the calyx, which is changed into a truncate cup. The flowers are panicled or corymbose, axillary lax and pretty and fragrant.

N. cymbium is a tree nearly 100 feet high, growing in the woods of the Orinoco, near S. Fernando de Atabasco, where it is called Sasafras, and also in the ancient forests of the Rio Negro in Brazil. The branches are smooth, the leaves oblong, lanceolate, papery, and shining above. The cup is large with a double edge. The bark aromatic, bitter, and stomachic. Martius suspects that it is one of the ingredients in the famous liqueur. It is known.

N. cinerariaeoides has oblong leaves tapering into a fine point, acute at the base, between papery and leathery, naked, smooth, and shining above; finely downy beneath, with numerous small narrow coralloid veins. The bark has the smell and flavour of cinnamon, as which it is used in New Granada.

N. Pachyrrhizus major has oblong or elliptical leaves tapering to a narrow point, smooth, reticulated, and of the same colour on either side. The cup of the fruit is very large and spongy. Martius assigned the Pachyrhum bean to this plant. In the early months of the year the fruits drop from their cups to the ground, and are collected by the natives, cleaned and dried by a gentle heat. They are prescribed in dysentery, diarrhoea, strangury, &c. The bark has the smell of coriander mixed with that of the plum, and yields the European Jamaica pepper. The bark is known as "Pepper", and is exported to the London shops. It is a native of the woods of Jahuatinga, in the province of Rio Negro in Brazil.

(Lindley's Flora Medica.)

NECTARINE. [Ampelodes, P. C.; Prach, P. C.]

NECTARY, in Botany, a term used by Linnaeus to denote those appendages of the corolla which secrete honey. The term has however, since the time of Linnaeus, been used in a general sense to express any organ existing in the flower between the corolla and pistil, and which could not be rightly assigned to these or the stamens. Such parts or appendages of the flower have had many other names applied to them, and some of the generic names are more frequently than nectary. A common form of appendage of the corolla is called corona. This organ is formed at the base of the limb of the corolla, and forms sometimes an undivided cup, as in Acetaea, and many others. It is here called the orbevix. When this appendage is accompanied with little projecting processes, they

* These are not the words of Plutarch: he says the feet were under the chariot, and "as they say, 'arxaios, when the figure was painted out." The exact meaning of this word is doubtful. Aristras was not in the chariot; he was standing by it. The word refers to a certain North, who translated Aristras, and who was a painter.
are called corona, or horns; the upper end of these is the beak or rostrum, and their back, if dilated and compressed, is called the corolla appendage. Occasionally there is a second appendage, which alternates with the first, and is called lipula; the circular space at the top of the orbiculus is the scutum. When the lamellae are small and scale-like, and overarch the ovary, they are called a fruit or fructification. Link proposes to call all appendages which are referable to the corolla paracorollae, or, if they consist of several pieces, parapellets, and all appendages referable to the petals, peculiar filament appendages of Passiflora he calls paraphyses or parastmates.

The real nature of these appendages is a point of some interest. Some botanists believe they are the simple excretions of the cellular tissue and epidermis of the part on which they are seated, and in others they are evidently abortive stamens or petals. Thus the little bodies found in the claw of the petals of Ranunculus may be regarded as an expansion of the tissue, whilst the filamentary appendages seen in the genus Passiflora are evidently metamorphosed petals. The various forms of corona may be assigned to one or other of the above causes. This subject requires investigation, and it would be well if a more simple and intelligible nomenclature could be applied to these parts of the flower; for, however unimportant at first sight such organs may appear, they nevertheless play an important part in the most valuable of all the distinctive marks for species, genera, and even orders, which the botanist possesses.

The original name, corona, of these appendages was applied to the crown or tiara, which the tenses of these organs frequently secrete. They were on this account called by Meyen compound glands. It was supposed by Kurr that the function of these glands was variegated, and that they only secreted honey till the fruit began to develop itself; and, as the function of the nectary has no direct relation with the object of the function of the fruit, that is, the development of the seed, is proved by an experiment by Kurr himself, in which he found that the seeds of plants became perfectly matured, although he had in the early stages of the growth of the flower removed the nectaries. As to what may be the determination of the nectary in these organs, any more than in other parts, no examination of their structure has hitherto pointed out. They do not however possess the power of secreting sugar and other secretions in any greater degree than the petals and other parts of the flower and fruit.

(Lindley, Introduction to Botany; Schleiden, Grundzüge der Wissenschaftlichen Botanik; Meyen, Pflanzen Physiologie.)

NEEDLE-ORE. [Mineralogy, P. C. S.]
NEGOTIABILITY. [Bill of Exchange, P. C. I]
NEG. OR NEJDJ. [Arabia, F. C. and P. C. S.]

NEUMATUM, a genus of plants belonging to the natural order Nympahaceae. It has many distinct carpels, half immersed in the profoundly honey-combed, obliterated teres, each bearing a style with a solitary seed in each carpel, with a sterile stigma at the destitute of lobes, and the base of which is thick and grey. The leaves are large and showy, white, red, or yellow. Both leaves and flowers rise from the surface of the water.

N. speciosum, Pythagorean Bean, has a polypetalous corolla and anthers drawn out beyond the cells into a club-shaped appendage. It is native in slow running streams and tranquil waters, in the warmer parts of Asia. The flowers are very beautiful, smelling of a rose, and generally of a rose colour, seldom white. A variety of this species, Tesserae, has its outer stamens sterile, dilated at the top, winged, obtuse, the appendage rising from a notch at the apex. It is native of Malabar. The flower resembles an insect once used in play by the French, called Lotus, and is one of the plants supposed to be the celebrated Lotos of antiquity, formerly found in Egypt. It was known to the Greeks, and is mentioned as growing in Egypt by Herodotus (ii. 92), Theophrastus, and others. Although not now to be met with in that country, there can be no doubt as to its having actually existed there, either naturally or in a cultivated state, for these authors speak of it in clear and decisive terms. It is noticed that the sculptured leaves are still preserved, which testify that this species, as the proper Lotos, has obtained religious reverence. It is spoken of as having been used as food by the Egyptians. Both roots and seeds are said to be injurious and to occasion swelling, and to be of service in extreme thirst, diarrhoea, vomiting, &c. In China it is called Linuwa, and the seeds and silves of the hairy root, with the kernels of apricots and walnuts, and alternate layers of ice, were frequently presented to the British ambassador and his suite, at breakfast, given by the principal mandarins. The seed is stuffed in salt and vinegar for winter use. Thunberg says this plant is held sacred in Japan, and is considered pleasing to the deities, that they may be propitious to the large boats. The seeds are somewhat of the size and form of an acorn, and of a taste more delicate than that of almonds.

N. tateum has a polypetalous corolla, and greatly resembles the species just described. It is a native of North America, in lakes and ponds: it has been naturalized as far as Philadelphia. The flowers are yellow, and resemble a double tulip. The seeds are very agreeable to eat, and are much relished by the Indians.

The species of this beautiful aquatic genus should be grown in cisterns, tubs, or large pots, in a rich loamy soil; they require a strong heat to flower to perfection. The pot they are in should be kept full of water while they are growing, but may be allowed to get dry when the flowering season is over. They may be increased by dividing the roots, but are obtained more readily from seeds, which vegetate freely. None of the species have flowered in this country excepting the N. speciosum; they all require a very warm situation in a stove.

Don, Gardener’s Dictionary; Burnett, Outlines of Botany.

NEMACANTHUS, a genus of fossil fishes from the oolite and liasian strata. (Agassis.)

NEMERTUS, a genus of fossil Annelids, from the Lower liasian strata of Lamberjack, in South Wales. (Murchison.)

NEMOCERA, the first family of Diprerior insects in the arrangement of Latreille, includes such species as have antennae composed of 18 segments, an exserted hind foot, a sheathed sucker, and either simple or toothed tarsal hooks. It includes the species of Cales and of Lipyla, the names given by naturalists to the Mosquitoe and Crandells. These Linnean genera are now greatly subdivided.

NEOTITIA (nowtia, ‘a nest with the young in it,’ ‘the young themselves’), a genus of plants belonging to the natural order Liliaceae, with a 2-lobed lip disseet at the base; the stigma transverse; rostellum flat, broad, prominent, entire, and without an appendage.

N. Nidus-anis, bird’s-nest orchis, is the only British species of this genus. The whole plant is of a pale reddish-brown; the root formed of many thick fleshy fibres, from the extremities of which young plants are produced. The stem is about a foot high, with smooth brown scales. It has no leaves. The spikes are dense, cylindrical, and many-flowered. It is the original Neottia of Linneus, and is native of Great Britain in stony woods.

N. repens, the common Hay-trefoil. (Bullock, A Dictionary of British Botany.)

NEPA, a genus of hemipterous insects of the family Hydrocorisae, the species of which are popularly known as water-scorpions. Their bodies terminate in two long setae, on the tip of which is a minute appendage. The body is covered with a film of air for respiration, when immersed in the water or mud.

NEPETOS, a name used by Pliny from nepos, escorpion, being supposed to be efficacious against the bite of a scorpion, or from Nepos or Nepote, a town in Tuscan, a genus of plants belonging to the natural order Liliatae, and the tribe Nepeteae. It has diverging anther cells, a ringent corolla, the upper lip flat, straight, emarginate, or hifid. The calyx is 6-toothed.

N. Cataria, catmint, has stalked cordate acute leaves, deeply crested and crenulat with a whitish pubescence beneath, dense many-flowered whortles, smooth and glabrous nuts. The stem is from 2 to 3 feet in height, downy or mealy. It is native throughout the whole of Europe and middle Asia, and is plentiful in Britain. The corollae are white, with a tinge of red spotted with purple. The whole plant has a strong smell between mint and penroyal. Cats are said to be fond of it, and hence it derives its name; they roll themselves on it and tear it to pieces apparently with much pleasure. Ray observed, as noticed by Pliny, that the scent of the sculpature of the garden were always destroyed by cats, unless he protected them with thorns until they had come into flower; but they never meddled with plants raised from seed; hence the old saying of ‘let no cat meddle with your garden; or in words which are not cat won’t know it.’ Ray accounts for this from the fact that by transplanting the leaves become bruised, and the powerful odour is exhaled which attracts the cats to it. It appears to
As a real aliphatic acid upon cats. Sheep are said to eat it, and thrive well in a light rich soil, and cut off root to root in a moist situation. All of them require a good deal of heat to flower well in this country.

(Don, Gardener's Dictionary; Lindley, Flora Medica; Burnett, Outlines of Botany.)

NET, and Marshal Spartianus,

PETRUS, a Roman jurist who lived under Trajanus and Hadrianus. Spartianus (Hadrianus) 4 states that there was a general opinion that Trajanus once intended to make Neratius Priscus his successor in the empire, instead of Hadrianus. However, this was employed by Hadrianus as he had been by Trajanus. A case is mentioned (Dig. 37, tit. 12, § 5) in which Trajanus acted on the advice of Neratius Priscus, and was commended (Dig. 1, tit. 2, § 2, § 47) that Neratius was elevated to the consulship, but the year of his consulship is not certain.

Neratius succeeded Cælius the father, and was therefore of the school of Proculus. His writings, which are mentioned in the Florentine Index, are fifteen books of Regulae, seven of Membranae, and three books of Responda. There are sixty-four excerpts from Neratius in the Digest. Neratius is often cited by the subsequent jurists. He is also mentioned by Gellius (iv. 4) as the author of a treatise De Nuptiis, but in place of Neratius some MSS. have Veratius in this passage of Gellius.

NERITES, a genus of fossil Annelida, from the lower silurian strata of Lampercht, in South Wales. (Murchison.)

NERIUM (from nöpö, humid, the habitat of species), a genus of plants belonging to the natural order Aporranthaceae. It has many species, of which the best known is N. oleander. In this plant a concentrated fluid is contained, consisting of about 80 per cent of oleander oil, and 20 per cent of oleander resin. The oleander oil is a thick, yellowish, viscid, aromatic liquid, and is volatile, and is used as a base for perfumes, and as a medicinal agent.

N. oleander, Common Oleander, has lanceolate leaves three in a whorl being beneath, the segments of the corolla trisid. It is native of the Indies, in humid places, but has not been found in Europe by the side of streams and the sea coast. The flowers are rather large, and of a bright red colour. This species contains a great quantity of gallic acid, and a decoction of the leaves or bark forms an accurate substitute for tannin, and is employed in the South of France to cure cutaneous disorders. The peasants in the neighbourhood of Nice use the powdered bark and wood of the Oleander to poison rats. Several cases are also recorded of persons having eaten meat rosted on a spit of Oleander wood.

All the species of Oleander are very showy when in blossom;
column of the Austrians, which he drove back into the forest, greatly contributed to the victory. At the peace of Launay he returned to Paris, where he was received with distinction by Bonaparte, who, in order to attach him to him, married Mademoiselle Auguié, a friend of Hortense Beauharnais. In 1803 he was appointed minister plenipotentiary of the French Republic in Switzerland; on leaving that country his personal qualities, which had made an impression on the court, were highly commended to him by his royal master, and in 1804 he was raised to the dignity of a Marshal.

On the renewal of hostilities with Germany in 1806 the direction of the eighth corps of the army was confided to Marshal Ney. A brilliant achievement in this campaign was the capture by storm of the village of Elchingen (October 4th, 1805), in which the Austrians, under General Laudon, lost fifteen hundred men killed and wounded and two thousand taken prisoners, was attended with the most important results. The impetuous courage and persevering skill which this marshal displayed on that occasion had been witnessed by Napoleon, who, in consequence of it, afterwards bestowed upon him the rank and title of Duke of Elchingen.

But it was perhaps during the Prussian campaign of 1806 that Ney's military reputation rose to its greatest height. Of the many splendid actions by which he distinguished himself, the most memorable was the taking of the towns of Erfurt (October 15th, 1806) and Magdeburg (November 11th, 1806) in which 23,000 prisoners were taken and 800 pieces of cannon fell into the hands of the French. In the battle of the Nations near Leipzig, the total destruction of a Prussian corps at Deppen (February 5th, 1807), the combat of Schomütten, by which the retreat of the Russians on Königswart was cut off, and, finally, the defeat of the left wing of the enemy at the battle of Friedland [Bonaparte, P.C.], which more than any other movement contributed to the victory. In September, 1808, he was appointed to a command in Spain, and he distinguished himself in the various engagements by which Galliéna and the Asturias were subjected. In Portugal, though under the orders of Marshal Massena, the merit of the capture of Chalad-Rodriguez (July 10th, 1810) and of Almeda (August 25th, 1810) have generally been attributed to him. He was also of great assistance to Massena in conducting his skilful retreat, after his failure in attempting to force the lines of Torres Vedras. [Massena, P.C.S.]

The different dispositions however of these two great generals soon brought about a difference of opinion, which ended in a serious dispute. The result was unfavourable to Ney, who was deprived by Napoleon of his command and recalled to France.

The disastrous expedition to Russia, and the command of the third corps of the grand army, in the course of which he appears to have freely expressed to Napoleon his dissatisfaction at some of his movements, and advised his retreat at the most propitious moment. At the battle of Valence (August 17th, 1812), at the battle of Teutres, and, above all, at the singularly disastrous battle of the Moskow (September 14th), from which he derived his title of False, he eminently distinguished himself, as the sirename by which he was known to the army, of 'Brave or the Brave.'

But it was during the calamitous retreat of the French army that he rendered it the most important service. The details of his are amply described in the histories of Ségur, Chambray, and Labanne; the first of these, however, though one of the finest models of historical style, should be read in conjunction with the Memoirs of General Gourgaud, who, with militarily unhappiness, and perhaps some personal hostility, corrects several erroneous statements of Ségur. One incident in this retreat is peculiarly characteristic of Ney's intrepidity and personal courage. General Dumas, in whose company he was resting down to breakfast at Ganninhenn, a man in a brown coat, long beard, and a weather-beaten countenance, entered his room, exclaiming, 'I am at last'; General Dumas, do you recognise me?' The general answered him, 'I did not know. I am the rear-guard of the army,' he continued; 'I have fired the last musket-shot on the bridge of Kovie; I have fought for the last hour, and now I am here.' General Dumas, do you recognise me? The general answered: 'The general is himself, and I knew him.'

In the campaign of 1813 Ney displayed his usual courage and energy in the greatly important matter of obtaining the victories of Bautzen, Lützen, and Dresden, the met with some severe reverses, and at the battle of Danemarvik (September 6th, 1813) he was signally defeated by the Russians and Swedes under Bernadotte, then Crown Prince of Sweden. The right wing of the French army, consisting of thirty thousand men, forty-three pieces of cannon, and three standards. After this disastrous engagement Napoleon had an interview with Ney's aide-de-camp, whom he interrogated respecting the matters of the day. Ney expanded at length, and 'after a few words led to it to the generals present, without giving expression to any feeling of dissatisfaction at the conduct of his lieutenant. 'The Emperor,' says St-Cyr, who is quoted by Alison [Hist. France, vol. ii., 1844], 'explained insatisfactorily the causes of the reverse, but without the slightest expression of ill-humour, or any manifestation of displeasure at Ney or any of the generals engaged. He ascribed the whole to the difficulties of the art of war, which he said he was far from being generally known. He added that, one day or other, if he had time, he would write a book in which he would demonstrate its principles in a manner so precise they should be within the reach of all military men, and enable them to learn the art of war as they learn any other science.'

After the abdication of Napoleon, in 1814, Ney withdrew from public life and retired with his family to his country-seat. It was there that, on the 6th of March, 1816, he received orders from the Minister of War to join the eighth military division, of which he was commander, and which was stationed at Besançon. Ignoring the motives of the order, he immediately proceeded to the reduction of the fortress of Besançon, and on the return of Napoleon from Elba. He then willingly undertook the duty which had been imposed upon him to lend his assistance in the organization of the new army of his former chief; and on taking leave of Louis XVIII, he assured him that he would bring back Bonaparte in an irons cage. As some doubts have been cast upon the truth of this boastful assertion of Ney, it may be well to state that he himself acknowledged on his trial that he used the expression. On leaving the king he travelled rapidly to Aix, where slept at the residence of his brother-in-law, the prefect of the department, who had zealously joined the restored Napoleon, and who made Ney acquainted with all the difficulties likely to attend any support of the Bourbon dynasty, and his own doubts on this subject increased as, advancing towards Lyon, he became more aware of the popular feeling in that part of France. The character of Ney was more fitted for the field of battle than for a political struggle, and it was only in the presence of danger that he showed resolution. Of this Napoleon was well aware, and he skillfully threw the weight of his influence and entreaties into the balance of Ney's already vacillating opinions. An earnest appeal to the early and glorious reminiscences of the prosperous days of the Empire, coming from his ancient chief, the creator of the facility which he had gratefully acknowledged to be the greatest service of this marshal. 'In the night of the 13th of March,' said he at his trial, 'down to which time I solemnly declare my fidelity, I received a proclamation drawn by Napoleon, which I signed.'

The order of the day relating to the capture of the bridge had been read to the troops, who received it with the most enthusiastic approbation. His defection was speedily followed by that of his whole army.

On the 22nd of June he joined the army at Lille, and was soon actively but unsuccessfully engaged with the British at Quatre-Bras. His conduct at Waterloo elicited equal praise both from friend and foe. His fruitless but resolute attempts at the head of the columns of the guard to overthrow the British before they could receive succour from the Prussians, are well known. Five horses were shot under him in this terrible conflict; still, on foot, his clothes pierced with balls, and his gallant charger, who, with militarily unhappiness, and despite his retreat which ensued, he was among the last to leave the field, and, as on the plains of Russia, he was the rear-guard of the last Imperial army. After the defeat of Napoleon at Waterloo, Ney returned to Paris, and remained there after the capitulation of that city to the allies, considering himself safe by virtue of the twelfth article of that capitulation. The following are the contents of the following article: All the individuals who are connected with the government shall continue to enjoy their rights and liberties, without being disquieted or prosecuted in any respect, in regard to the functions of public conduct or opinions. (Convention, July 3rd, 1815.)

On the 24th of July however appeared a Royal ordinance, in which, among several others, he found himself proscribed as a traitor to the country. To escape the danger he endeavoured to fly France, but was met on the 7th August, at
the château of Bousons near Aurillac. He was at first cited before a council of war, which declared its incompetency to sit in judgment on a peer of France. His trial was then removed to the Chamber of Peers by another Royal ordinance of 1826. The proceedings were conducted by his eloquent advocates, Berreyer and Dupin, and chiefly rested on the article of the capitulation above alluded to. The result however was that he was found guilty, and condemned to death.

On 7th December, 1815, the day after his condemnation, an officer presented himself to Ney to communicate to him the sentence, which was to be carried into immediate execution. On his leaving Ney, the mob, who had collected, rushed up and cried suppliantly Michael Ney, now a French soldier, and soon about to be a heap of dust.' A spot in the garden of the Luxembourg was selected for the execution; he met his fate at eight o'clock in the morning with calm courage. 'He who had fought five hundred battles for France—not one against her—was shot as a traitor.' (Napier, Hist. of the Peninsula War, vol. ii. p. 405.)

The refusal of Alison on this event are creditable alike to his impartiality as an historian and his feelings as a man. 'The death of Ney,' he says, 'is a subject which the English historian cannot dismiss without painful feelings. His guilt was self-evident; and never was the penalty of the law inflicted upon one for a political offence who more richly deserved his fate. The question of difficulty is, whether or not he was protected by the capitulation of Paris. The clause in the treaty, which states that no person should be molested for his political opinions or conduct during the Hundred Days; it is very difficult to see how this clause could be held as not protecting Ney, who was no supporter of the Bourbons. But however the views of the Blücher concluded the capitulation: their Sovereigns ratified it: Louis XVIII. took benefit from it. How then can it be said that he, as well as the allied sovereigns, were not bound by the treaty, especially in so vital and irreparable a matter as human life—and that the life of such a man as Marshal Ney? It is very true a great example was required; true, Ney's treason was beyond that of any other man; true, the Revolutions of 1830, of 1831 and 1832, were more than two only; but all that will not justify the breach of a capitulation. To say that Louis XVIII. was not bound by the capitulation; that it was made by the English general without his authority; and that no foreign officer could tie up the bands of an independent sovereign, is a glib unworthy of a generous mind, and which it is the duty of the historian invariably to condemn. This was what Nelson said at Naples, and what Schwarzenberg said at Dresden; and subsequent times have unanimously condemned the violation of those two capitulations. Banished from France, with his double treason affixed to his forehead, Ney went to the Atlas Mountains, of the Egyptian tribune of the world his guilt will be forgotten in the tragic interest and noble heroism of his death.' (Hist. of Europe, vol. x. p. 975-977.)

The following works may be consulted for a full detail of the life of Marshal Ney: Vie du Marshal Ney, with Histoire de son Procès, Paris, 1816; Bicé des Générals Français, par Courcelles; Histoire de Napoléon et de la Grande Armée, par Segur; Histoire de l'expédition de Russie, par Chambray; Alison, Histoire de l'Europe, vols. iii. iv. v. vi. x.; Court and Camp of Napoleon; Mémoires de Rapp; Napier, Hist. of the Peninsula War: Mitchell, Fall of Napoleon: Remy critique de l'Histoire de Ségur, par le Gén. Gourgaud. The arguments in favour of his condemnation may be seen in the works of Bellart, the crown prosecutor, Affaire du Marshal Ney, Paris, 1816; SCHRÖDER LIEB. [GERMANY, F. C. P., 1841.]

NICÉRON, JEAN-Pierre, was born at Paris in 1685. He entered the regular order of Barnabites, and devoted himself to the study of languages and biography. He lived a life of quiet incident, and died at Paris on the 8th July 1733. He is chiefly known as the author—or in some parts rather the compiler—of Mémoires pour servir à l'Histoire des Illustrés dans la République des Lettres, of which twenty-four volumes were added after his death. All who have had occasion to study the earlier literary history of France must be under obligations to this work. Important works of modern are necessary very high in criticism, philosophy, or the essential elements of spirited and descriptive biography. Nicéron was however a curious and laborious reader, and in those instances where he exhibits the fruit of his original research, his matter is highly valuable. Many of the livresses hereover are mere compilations from other sources, and appear to have been hastily prepared to suit the order of publication. There is little attempt at a proportional distribution of space, sometimes with simple and occasional annotations as elaborate as the most distinguished men of their age. This is a defect sometimes unpleasing, as it generally attains enthusiasm in some particular walk of literature, and marks the original editor for his own taste.' (Napier, Hist. of the Peninsula War, vol. ii. p. 405.)

NICOLAS, ST., situated in 51° 6' N. lat. and 4° 8' E. long., is a large market-place in the province of East Flanders, of the kingdom of Belgium. It has a large market-place surrounded with good bouses, a handsome town-hall, a prison, a tribunal of commerce, and a Latin school. The number of inhabitants is about 18,000, who manufacture cotton and woollen goods of various kinds, hats and ribbons; there are tanneries, potteries, dyu-houses, brick and tile kilns, soap-works, suit-works, &c. There is a great weekly market for corn, flax and hemp, and horses. St. Nicholas is in fact one of the richest and most flourishing towns, not only of Flanders, but of all Belgium. The surrounding country is highly cultivated.

NICOLAS (Nicolas) of Athens, the son of Nicomedes, and the pupil of Antidotus, was one of the most celebrated painters of antiquity. He was, though probably younger, contemporary with Apelles. He is described as the producer of the picture: in elegant design, in beautiful colour, and in effect colour's适应; in fact, in the characteristic qualities of the Bolognese school subsequent to the Cerasi. He also excelled in painting history; but this work fell into disrepute as a result of his mastery over the instrumental and technical parts of art. It is remarkable, though Athens was so long the principal seat of the arts among the Greeks, about two centuries, Nicias and Apollodorus are the only two Greek painters of the greatest fame who were natives of Athens. Yet the case is very similar with modern Rome: of all the great painters of that central city, two only were natives—Giulio Pippi, called Romano, and Carlo Maratti.

The most celebrated work of Nicias was the Naxia, or the region of the shades, of Homer (Homeri Homerum); from the passage of the Odyssey where Ulysses invokes the shades of the dead. Nicias, says Plinius, refused to sell this picture to Ptolemy I., of Egypt, who offered him sixty talents for it; he presented it to his country. If Plinius speaks here of the Attic talent, the price offered was enormous, though not unprecedented in ancient times—about 15,000, according to some computors of money; but whether the amount, which is unlikely, the amount would be diminished to nearly one-fourth.

Nicias must have been old when Ptolemy was king of Egypt; and from his refusal of this offer, probably very rich also, as Pliny says that Ptolemy offered him a thousand talents for the picture of Napoleon, Egypt in 306 B.C., and, Nicholas, about half a century earlier, was employed by Praxiteles to colour some of his statues. Pliny infames a doubt whether the same artist in these two cases is alluded to; and Silius, in his Catalogus Artifictum, has concluded that they cannot be the same. Only one Nicias, however, is known and spoken of by ancient authors; and the only reason for doubting the identity of these two is founded on Pliny's method of assigning their dates to artists and their scholars, mentioning only a single year or Olympiad for each, which, vaguely expressed as it always is, need give us the exact time of an artist within half a century. Yet if we consider enough of the commencement of his career, we make him probably contemporary with a generation of artists who succeeded him; and if we suppose him to have been about seventy years of age, and he was doubtless old, with such a reputation and sue independence, he may very easily have many years before painted the statues of Praxiteles. Praxiteles described, according to Pliny, in Olymp. 104; and if this date is to be understood as the beginning of his career, he was essentially the contemporary of Nicias; and if as the middle, he was about one generation his senior. This is in all probability the case;
for it reconciles all the facts recorded of Nicia, and it is much more probable that Praxiteles would employ a young man to collaborate with his own hand, than that he would use a pupil who was his in name only, a great painter, his equal in age and reputation. Statue-painters, *Psycos* και *Hyrcanus*, constituted apparently a class of themselves, and Nicia may have been one of these in Praxiteles' time. It is more probable, however, that one of the greatest painters of his time should be thus employed. One of Silius' difficulties in identifying these two as one, is, that Nicia was the pupil of the pupil of Euphranor, who was the contemporaneous, if not the original Praxiteles. It is impossible however, to suppose that there must necessarily be a generation between master and pupil: the master is frequently only a very few years older than his pupil, and is sometimes even younger than the pupil. We suppose that if Nicia was a generation younger than Praxiteles, there is not the slightest difficulty in the way of his having been the pupil of the pupil of a contemporary of Praxiteles.

Nicia painted in easecue, and besides the one already mentioned Pliny notices the following pictures by him:—an Alexander (Paris), a sitting Calymnus, an Io, an Andromeda, and another Calympo, in the hall of Pompey; a Bucephalus, a Diane, and a Hyacinthus, in the temple of Concord. The Hyacinthus was brought to Rome by Augustus from Alexandria, and was consecrated afterwards by Tiberius in the temple of Augustus, on account of his great delight in it: it is said to have been drawn from Silanetus, (iii. 10), who says that the figure of Hyacinthus was very elegant.

Augustus dedicated and fixed in the wall also a picture by Nicia in the Curia Julia, of Nestor sitting on a lion, holding in his hand a tablet, of which he was substituting an old man, resting upon his staff; above him was hanging a picture of a Biga. It was brought from Asia by Silanetus, and was most probably the same of which a Tarentine ambassador, being asked his opinion, said, according to Pliny, 'that he would not have had it even if he were real and living,' alluding to the old man with his staff: entirely overlooking the art which embodied the picture, and measuring the man apparently by rules, the Lesseps (Lesbia, p. 360, note: *Cicero*), proposes to substitute in the place of the picture of the Biga, (tabula Biga) hanging above the man's head, which he supposes to be a corruption of the text, a *nema tablet*, called by the Greeks *epitaphion*. Nicia wrote on this picture that he had burnt it in, *Niciae epitaphion*, that is painted it in easecue.

These words were, in the opinion of Lessing, written upon the small painted tablet which was hanging over the head of the old man—νεμεια επιταφιων της ευθειας. *Niclae scriptum est instanter; tali enim est verbo. The passage is obscure; only one picture is spoken of; the words *tabula Biga* may be corrupt; it is certainly difficult to give them a suitable meaning, and the subject remains, however, as respect to the Neumatic games, because in them four horse-chariots were used. (Schmidt, in *Proef. ad Nemeiaecus*, p. 2.)

Nicia enumerates the poems of the tribute of Augustus, high priest of Epheusus, and one at Tiuma. Pausanias says, before you come to Tiuma from Phravre there was a *Apis* of white marble, which was particularly worthy of inspection on account of the name of Nicia upon it: a beautiful young woman was represented seated on an ivory chair, and behind her was a female servant holding an umbrella; a beardless youth also was standing near her, dressed in purple: by the youth was an attendant with hunting spears and a leash of dogs (Nicia was, according to Pausanias, the most excellent animal painter of his time); the names of these people were not known: Pausanias supposed these to be man and wife. Nicia was honoured with a public burial, and was interred in the road from Athens to the Academy, the cemetery of all great Athenians: Pausanias notices his tomb there. He appears to have been a very studious painter. Augustan says he used to forget to take his meals (Var. Hist., i. 31).

It has been said above that Nicia painted some of the statues of Praxiteles: this requires some explanation. Philemon of Praxiteles brings marble statues be preferred, answered, 'those which Nicia had had a hand in; so much did he attribute to his circumlucio.' This word *circumlucio* has been variously interpreted. 'Pacellus' (Pacelli) supposes it to be an application of the clay model; but Pliny is speaking of marble statues, and the circumlucio must have been some superficial application, and cannot be applied to a correction of form; the question is a process which has undergone at the hands of a painter. Cicero has 'Persae mortuorum cera circumlucitos conditum.' (In Tusci, i. 45.) There is a prejudice against the idea that the Greeks painted their statues. It is an indisputable fact, though it was not a universal practice. The statue-painters, χρυσαυτομοικζωνετοι, as Plato calls them, are definitely spoken of by Plutarch (De Glor. Athen. 6.) as *Chrysoautumoeiakrovkteri*, or painters of art itself as *Chrysoautumoeiakrovkteri*. Statues seem to have been sometimes entirely painted, which appears from the following words of Plato (De Rebip. iv. 420. c). He observes, in speaking of the mastic and linseed paint which was used, that the Ionian logicians and Aristotelians, in the dialogue of the Portraits, or Pois, in Lucian; from which it is plain the Venus of Cnidian, by Praxiteles, and other celebrated statues, were not painted, though parts may have been coloured, and the whole body covered with an encasual varnish. (Lucian, Imag. 5-8.)

We may infer therefore in this case that the circumlucio of Nicia, applied to the marble statues of Praxiteles, was the *Chrysoautumoeiakrovkteri*, or some of his pupils.
NICOLL, ROBERT, a poet distinguished by the precocity of his talents, was born at Tullibeltane, in Perthshire, on the 7th January, 1814. His parents were in too humble circumstances to afford him any education beyond the rudiments of reading and writing; but he saved the money he earned by labor of various kinds, and was enabled to purchase books and to acquire a knowledge of those parts of Greece and Rome which he afterwards translated. He had been apprenticed to a grocer in Perth, and at the conclusion of his service endeavoured to earn a livelihood by keeping a small boarding-house. His business was commenced with the least possible expenditure of capital; for he had been acquiring the elements of knowledge. He was a devourer of books, and at the age of twenty had acquired both knowledge and cultivation without being educated. In 1836 he undertook the editorial supervision of the ‘Leeds Times,’ a paper of strongly liberal sentiments; and by the spirit and energy of his political articles, and their adaptation to the feelings of the surrounding community, he soon more than tripled the circulation of the paper. His early struggles had probably undermined his constitution, and he soon sank under the exactitude of his editorial labours. While he was engaged in his duty, he had his hair cropped, and the neighbourhood of Edinburgh, where, amidst the attendances of kind friends, he died on the 5th of December, 1837, in his twenty-third year.

Memoir, by Mrs. Johnstone, prefixed to a third edition of his Poems; Westminster Review, No. 76.)

NICOMACHUS (Nicoiædæus) of Thessalon, son and pupil of Aristarchus, and of Artemisia; he was a painter of the fifth rank, whose works between 360 and 300 B.C. He is classed by Cicero with Apelles and Protagoras, and his paintings are compared by Plutarch with the times of Homer: he was the most celebrated of all the Greek painters for rapidity of execution. In illustration of the rapidity of his execution, Pliny mentions the decorations of the monument which Aristatus, tyrant of Sicily, had erected in honour of the poet Telesetes, which were executed in a few days by Nicomachus, with remarkable beauty, and to the entire satisfaction of Aristatus, who shortly before was exceedingly angry with him, for, as he supposed, neglecting his contract, which was to have the tomb finished by a certain day. Nicomachus had deferred the commencement of the tomb so long, that Aristatus concluded he did not intend to meet his engagement: the painter, however, was a better judge of the required time in his own case.

The notices of Nicomachus are few, and what there are contain but little information about him. Pliny mentions by him—A Rape of Proserpine in the Temple of Minerva on the Capitol, hanging above the niche or shrine of Venus or Youth; and a Venus embracing a Youth, with which was dedicated by Piancus; also Apollo and Diana; a Cybele, the mother of the gods, sitting upon a Lion; Bechecantes, with Satyrs creeping up to them; and a Scylla, which was in the Temple of Venus at the entrance of the port of the Tyndarean by Nicomachus; he instances it as an example of the unfinished works of painters being in greater repute than their finished works, when left unfinished through death, or perhaps other circumstances impeding their completion: he mentions four pictures—the Tyndarean of Nicomachus, the Iris of Aristides, the Medea of Timonmachus, and a Venus of Apelles. Nicomachus is the first who represented Ulysses with the pileus or cap of liberty. He is one of the painters from whose error Pliny’s is said to have used only four colours. (See Dictionary of Greek and Roman Antiquities, article Colors.) Cicero, in speaking of these works, says they are arranged in the works of Eucleon, Nicomachus, Protagnoras, and Apelles, all things are perfect. He is, however, enumerated by Virgil among the artists who thought of the greatest ability the works of these master-painters, and of Alianus, who relates of Nicomachus that, bearing some one say that he saw no beauty in the Helen of Zeuxis, he observed—‘Take my eyes, and you will see a master.’ He had several scholars among his celebrated painter, his brother Aristides, his son; Philoheus of Ecretia; Neoepheus; and a certain Corylas. Philoheus imitated Nicomachus in celebrity. Nicocles was a painter of Corcyra.

(Pliny, Hist. Nat. xxxv.; 30, 35; 11, 40; 14; Cicero, Brutus, 18; Plutarch, Tim. 36; Vitruvius, lib. in procœss.; Stoicœ, Ser. 61; Julia, Catalogus Artificrum.)

NIGELLA (from Niger, black, because of the colour of the seeds), a genus of plants belonging to the natural order Ranunculaceæ. It has 5 coloured petal-like spreading sepals. The petals small, from 5 to 10, bilabiate, with a hollow nectariferous claw. The capsules more or less connected to each other, terminal, dehiscing by 4 or 5 teeth, and give rise to the lot of the perennial grass. In the wild N. sativa has ovate obtuse anthers, capsules muricate, united up to the very point into an ovate fruit, terminated by five crest styles; the stem erect and rather hairy; flowers naked. This herb was formerly used instead of pepper; and have also been employed as a condiment. It is the Mallophora of Hippocrates. [Steril.] 675, and of Dioscorides, 3, 83; the Glycy of Pliny, 17, 20.

N. arvensis has pointed anthers; from 5 to 7 styles gradually revolute, outwardly smooth; capsules connected below the middle into an oblong fruit, which is narrowest at the base. It has a smooth stem, with diverging branches. It is native of middle and southern Europe in corn-fields, also in the north of Africa. The seeds are sometimes used instead of those of N. sativa, but they are not so aromatic, neither have they so pleasant a smell. In Egypt they are used in the adulteration of pepper. All the species of Nigella are plants of easy culture, only requiring to be sown in the open border. They are curious and ornamental.

(Don, Garden Dictionary; Linnaeus, Flora Medica; Frag, Synopsis Plantarum; Flora Classica.

NIGRIATIA is a term, which was formerly applied by geographers to that part of Africa which lay between the latitude of 20° N., the name of Stobo with which Arbuthnotian it is only a translation, meaning the country of the blacks. (Soodan, P. C. vol. xxiii.)

NILE. Since the article Nile was printed in the P.C. the course of the western branch of the river, the Bahr-el-Abiad, has been traced to 4° 42' N. lat., which is nearly nine degrees south of Aleis, to which place it had been explored by Linant. In 1840, 1841, and 1846, parties of Egypt sent three expeditions for the purpose of exploring the course of the river to its source, and the two last expeditions were accompanied by several scientific Europeans.

South of Khartoum (10° 17' N. lat.) and as far south as Aleis the Bahr-el-Abiad is in general from one to two miles wide, and runs in a bottom, which is generally four miles wide, but sometimes even six miles. The bottom is covered with grass and the higher grounds at the back of the trees. There occur a few low hills in this part of the country. The western banks of the river are occupied by the Hmani, a nomadic tribe of Arabian origin, the most southern of this description, a Valet of the same tribe, and wage war against the black tribes who live further south, especially the Shillucks.

South of Aleis begins the country of the Shillucks, which extends to about 10° N. lat. The river is here three miles wide, and contains of 100 or 120 feet. It is overgrown with trees and shrubs, and frequently several miles long and a quarter of a mile wide, and nearly all of them overgrown with high trees and bushes. On the western side is a mountain group, called Arabshali, which is crowned with seven peaks; between this high ground and the banks of the river are extensive forests. In these forests are numerous villages, which when seen from the river appear to be regularly arranged in three rows parallel to the river. They are inhabited by the Shillucks, a practical nation of blacks, who frequently descend with their boats in great numbers to the countries lower down the river, and formerly extended their predatory incursions as far as Khartoum, but at present they are kept in awe by the banks of Egypt. Near the southern limits of their territories the country is interwoven with numerous isolated conical hills, among which one called Defa Fung (10° 20' N. lat.) appears to be an extinct volcano, containing a large lake in its crater.

Near 9° 11' the Bahr-el-Abiad is joined from the east by a large tributary, the Sobat, which is supposed to rise in the mountains of Abyssinia, and which flows a course of some 120 miles, parallel to the course of the principal river. The lower course of this tributary was explored, and it was found that it runs between banks, which are much higher than those of the Bahr-el-Abiad itself, and well wooded. Soon after the mouth of this river to Khartoum the Bahr-el-Abiad flows from south to north, but higher up it runs from west to east for about a hundred miles, through a country inhabited by another black nation, the Dinika, who are divided
into seven tribes and speak a language different from that of the Shillucks. In this part (between 8th and 9th lat.), the river appears to traverse an immense swamp interspersed with many smaller and larger lakes, one of which is stated to cover an area of 420 square miles. The current of the river through these low grounds is imperceptible, and its water divided into so many branches, that it is difficult to find out the main channel. It is supposed that the great quantity of water which collects in these parts is brought down by a river running from north-west to south-east, which is the only branch which the Arabian geographers is called Kallack. It is also possible that the course of this river has induced them to adopt the opinion that the Behr-el-Abiad rises far to the west. The Disko is a wandering and semi-nomadic tribe, which, live principally on the produce of their herds of cattle, distinguished by large horns like those of antient Egypt. They are less strongly built than their northern neighbours, the Shillucks, and it appears that their health suffers from their residence in the swamps. In this region, elephants, giraffes, and hippopotami are met with in great numbers.

Before the Behr-el-Abiad enters this swampy region it runs from south to north, but farther upwards (south of 7th lat.) from south-east to north-west. The country traversed by it is a plain, completely naked, and with even rapids. Its eastern banks are occupied by the Nuers, and its western by the Kys or Kekes. Both nations are cultivators of the ground, but have also numerous herds of cattle. They are not agueous. The colour of their skin inclines to the red, and their hair is smooth and lank, not woolly. They have enclosures round their huts, and others for their cattle. The Kys have also numerous beds of melons, but live chiefly on rice, fish, grain, and roots. Both nations received the expeditions with confidence and joy, and presented to them a great number of cattle. It appears that these tribes speak a language which is understood by the Binkas.

Farther upwards other tribes are named, as the Heilab, Bhor, and Chir. At last the expeditions arrived in the country of a black nation called the Barrys, where their progress was stopped short by a vast lake, which the river in its width near 4° 42' N. lat. and 50° 38' E. In approaching 5° the bed of the river, which up to these parts appears to be formed by alluvial soil, begins to be rocky, and at the same time mountains become visible, which extend from east to west. The river by degrees acquires such a velocity as to run six knots an hour. According to the information obtained from the mutta, or king of the Barrys, persons must walk for a month before they arrive at a country called Anyan, where the river is forded by the confluence of four rivulets, the largest of which comes down from the east.

The Barrys are described as a very interesting nation. They possess a peculiar and splendid country. The Barrys is a country well cultivated and exhibits the richest crops, their fields being irrigated by numerous canals. They enjoy a considerable amount of ease, which appears to have a great influence on the frame, constitution, and manners of the human beings. They are in general more than six Paris feet in height, and are well built. They inhabit a great number of villages, consisting of huts built of reeds, and situated either on the banks of the river or at a distance from them; some are built on hills. They cultivate dhurra, sesame, tobacco, and several kinds of melons. No horses, camels, or asses are found in their country, but their cattle are of great size and very numerous; they also have fowls in abundance. Among the wild animals, elephants, giraffes, and antelopes are very numerous. In the mountains lying towards the east iron-ore is abundant, and they have also rich natural implements, knives, and arrow-points. They are also acquainted with the art of tanning and making some cotton fabrics, and working copper and ivory, which they employ as ornaments. The king is said to live in a palace, built on an island, to which his subjects can only arrive by swimming. He is surrounded by a guard composed of women. It was observed by the persons who composed the expedition, that the inhabitants were in possession of several articles of commerce peculiar to India, as calabashes made at Surat, as also swords and other arms of iron. The natives stated that all these articles were brought to them from a commercial place which they called Berry, and which, as they said, is a day's journey farther east, at the foot of a range of mountains.

The task for us is to account for these expeditions that the interior of Africa is much more populous than was supposed, and that several of the nations inhabiting it have attained a considerable degree of civilization.

(Werne, Uber die zweite Expedition welche auf Befehl des Pascha von Assyrgen Mohamed Ali zur Erforschung der Quellen des Wissen Nils unternommen wurde. In den Mem. de l'acad. des sciences, t. v., p. 80, 1845.)

NIMA, a genus of plants belonging to the natural order Simaroubaceae. It has hermaphrodite flowers, a 5-petalled calyx, 5 stamens, 5 ovary, in a capsule, anthers containing spores dilute at the base; the 5 ovaries are connected together, pilose, and seated on the thick disk beneath the petals. The embryo is large, without albumen. The species are herbaceous, tree or shrubs; among the best known are a number of species differing by sparsity, with pairs of serrated leaves. The flowers are disposed in panicle corymbs.

N. quaissica is a native of Neapal, in a valley near the town called Thahkt. It has elliptical oblong leaves, which are acuminate and serrated. The corymbs are biclinomous. It is as bitter as the quassia of South America.

(Gardner's Dictionary, Lindsay, Flora Medicina.)

NINEVEH. Since the publication of the article NINEVEH in the 'Penny Cyclopedia,' discoveries of the highest importance have been made, not on the precise site, yet in the immediate vicinity of the ancient city, by which the following are some of the most interesting particulars.

For these discoveries we are indebted to M. Boita, consul of France at Mosul on the Tigris, opposite to the presumed site of Nineveh. In the year 1843, announced to his friend the intention of employing what leisure the duties of his office might allow him in making excavations at Nineveh. He began with some operations in the immediate vicinity of the town of Khoser (Khasar, M. Boita's researches in this place not only proved more successful, but have led to discoveries of the highest importance, which, if the numerous cuneiform inscriptions can be deciphered, will doubtless throw great light on the ancient history of Asia. Commencing his excavations in a small mound, his workmen soon came to a monument, remarkable for the number and style of the sculptures with which it is adorned, and which appears to have been a palace. During the progress of the work, with M. Julius Mohi, at Paris, to whom he wrote sixty letters, with drawings of the sculptures and copies of the inscriptions, M. Mohi published notes of the most remarkable, which are inserted in the 'Journal Asiatique,' and they have since appeared in one volume, with fifty-five plates. M. Boita regretted that he was not a competent draughtman, and wished the government to send him a good artist; and as soon as the French ministry were aware of the great importance of the discoveries, they sent him M. Flindan, an able artist, who had lately returned from Persia, and granted some money to enable M. Boita to prosecute his researches. The following particulars are extracted from M. Boita's letters, and such parts have been selected as may be understood without the plans. He has great deal of importance in the sculptures exposed were thrown in his way by the ill-will of Muhemmet, Yassar of the Pasha of Mosul. All are now happily surnanted, and the excavations are terminated (in 1845). M. Flindan has...
returned, with drawings of 150 bas-reliefs; and the greater part of the sculptures (weighing it is said above 300 tons) have been sent to Bagdad, to be embarked on board a vessel to proceed to France. A large number is now in the Assyrian museum. M. Botta is we believe now at Paris, with copies of 200 inscriptions, and will publish an account of his great discoveries, with engravings of all the sculptures and inscriptions.

From M. Botta's third letter, dated Mosul, June 2nd, 1845.—I return with increasing astonishment from my discoveries at Chorsabad. My operations have again brought to light several of the chief scenes of the monument. On the north wall of the apartment there are, first, some figures, of which only the feet remain; then a bas-relief, on which there are two archers standing and two kneeling, who wear coats of mail, and have an inscription over them. These archers are shooting at a fortress, which is taken by storm. The fortress consists of an embattled wall, strengthened by projecting towers; at the bottom there are undulating lines, probably representing a river or the water of the moat. Within this wall there is an eminence with a castle upon it, from which arise what I suppose, from their red colour, to be intended to represent flames. At the other extremity there are three warriors armed with pikes, holding their shields over their heads, and ascending a ladder; others have already reached the top; and in the intervals between the towers others are mounting scaling ladders. At the other end of this apartment you may see a. On each side of this is a passageway of the same width, but much damaged; we only see that one of the soldiers pursues an enemy with his sword; a man pierced with an arrow is seen falling from the top of the wall; and on several parts of this wall there is a bas-relief of a horseman. There is also a group on the bottom there is a row of wretches impaled. On the top of the hill there is a short inscription, probably containing the name of the fortress. The whole is very animated. The attitudes are varied, and through the heads of the figures are scarcely an inch long, the expression of the features is excellent.

After this bas-relief there are on the same wall five war-chariots following each other, turned to the fortress, and evidently meant to represent a battle. These chariots are all alike. The horses are in full gallop, and trample with their hoofs on a man lying on the ground. There are five persons in each. The principal figure wears a pointed tiara, and is discharging arrows; beside him is the driver, and behind them two warriors, armed with darts and wearing bucklers. Above there is a man who seems to be wounded, and thrown into the air with the head downward. The singular position of this figure is perhaps meant to indicate the confusion of the battle, or the rapidity of the chariot, which violently throws to the ground all who entered it. On the left of this inscription is a bas-relief of a horseman, which is extremely animated; the horses in particular are very spirited. The harness of the horses is very rich, and has evidently been coloured. These five bas-reliefs are each separated by a perpendicular line at the edge of each slab; and over them is a long inscription, which at first seems to be continuous, but it is certain that it is divided into parts, each bounded by the edge of the slab on which it is sculptured. Each inscription is a separate line at the edge of each slab, and separates the inscriptions, which differ in the number of lines.

M. Botta describes several other figures, and proceeds:—

'This description of these newly discovered sculptures is very incomplete; to describe them in detail would require a volume. I doubt whether more richly decorated walls are to be found even in Egypt. In the whole monument there are scarcely a few feet without sculptures, and inscriptions. The mode of building is everywhere the same. The walls are formed of enormous slabs of gypsum or alabaster ten or twelve feet square, and scarcely a foot thick. The alabaster is larger and lighter than in Greek sculpture, but higher than the Egyptian. Though rather stiff they are well designed, the attitudes admirable, the musculature strongly marked, and the hands, feet, and figures are admirable. The builders have to be supposed that the building has been destroyed by fire; on the ground were found a quantity of charcoal and some remains of burnt beams.

The surface of the slabs is in many places calcined by fire and fire. There are other portions of a slabs of this kind, which are probably destitute to determine the age of the monument, I shall refrain from all discussion on the subject, and merely state some particulars which may aid them in their researches. Though the hair, the beards, and the costumes resemble the Sasanide modes, I have found no trace of any inscription in a different character; in one part of the building there is no inscription, and some parts of the buildings have on the back cuneiform inscriptions evidently injured by time, in characters exactly resembling those on the present monument."

M. Botta in his fourth and fifth letter continues to give an account of the progress of his discoveries; among the most interesting are two colossal statues of bulls fifteen feet high, with human heads, and between them a passage seven feet and a half wide, forming, as he presumes, a portal of a striking character and of great magnificence. These bulls were winged; they are not properly statues, but in high relief. On clearing the passage it was found that the bodies of the bulls were continued on the walls in low relief. These figures are of large dimensions, 18 feet in length and high in proportion. They have five legs each, so contrived that whatever side you look at them, one leg being hid by another, four legs are always to be seen. On the left side of the wall, at the entrance, there is a figure with the head of a bird of prey; the hair is regularly braided, on the head is a sort of cap which comes down to the shoulder. The figure has a neck of great rarely, and is divided into several parts, with fringes. On the opposite side of the chamber, M. Botta afterwards found a similar portal. M. Botta resolved to send two of these bulls to Paris.

'This discovery concludes, to fail to engage the attention of the learned; but unfortunately the greater part of these remains has already disappeared. The walls are not solid, but formed of slabs of gypsum or alabaster, with an interposing space which is filled up with earth. This earth, says M. Botta, 'has caused the walls to bulge in many places, and broken the sculptures into a thousand fragments since I have cleared them. Having nothing to support them, they would fall did I not take the precaution to shore them up as I proceeded; but as these supports will last only during the operations that I am carrying on, the monument will necessarily perish entirely if the enlightened munificence of the French government does not furnish me means to save the most interesting portions.'

In a report to the Minister of the interior, M. Botta says, 'The bulls in Chorsabad, the monument which had been suspended for two months on account of the heat, 'much regret that a great part of the sculptures are already destroyed. The inhabitants have stolen the props which I had placed to support the monument, the moulds of the walls to fall. I am extremely sorry that M. Flandin has not yet arrived.'

'I am still in doubt,' says M. Botta to M. Mohl, 'respecting the destination of this monument; whether it was a palace or a tomb. The latter seems the more probable, because the interior must have been completely dark; for there is no appearance whatever of windows. At all events, the extreme richness of the decorations, and the number of battles represented, prove that it must have been built by a rich and powerful monarch.'

'It is to be hoped that the 300 tons weight of the sculptures sent by M. Botta to France, and the 200 inscriptions, and the drawings of M. Flandin, will enable the learned antiquarians of Europe to throw much light on the history of those remote ages.

The writer of a private letter from Constantinople says, 'M. Flandin's drawings, which we had the good fortune to see a few days ago, will greatly interest the public in general as well as antiquarians—the manners and customs, the religion, the art of war, the battles, the fêtes, and the funerals—of the Assyrians. The fact is that it is certain that the bulls have the two horns forming the corners bown out of one piece, and have been cut according to the dictum of this school; but this is not the case. There is a chance that these inscriptions being so placed that they could not be seen while the building remains entire, we need only suppose that their contents are of a halluciatory, religious, or oracular nature, and were purposely concealed, the plates which M. Flandin found in deep recesses in the walls; which could not be got at as long as the walls remained entire.'

* M. Mohl has published only five of M. Botta's letters.
who built Khorsabad, are here delineated in plentiful copies of the bas-reliefs. The principal figure in most of them is a sovereign, king, or hero; on his head he wears the tiara, his form is prominent, his epauletts thick; his beard and beard falls straight on the shoulders and breast, terminating in large ringlets. The dress, which appears to have been extremely magnificent, consists of a richly embroidered tunic or jupon, set off with a rich sable cloak. It resembles the surplice of the Roman Catholic priest.

This figure appears, sometimes engaged in combat, driving his enemies before him; sometimes seated at an entertainment; and sometimes in a solemn procession. It is apparently a fragment from one of the statues of theTEAM,7. From the first to the last several figures for females, but afterwards changed his opinion, and thought they might perhaps be mean for eunuchs.

(Lettres de M. Botta, sur ses Découvertes à Khorsabad. p. 195.)

N. nitidus, a genus of fossil fruits, from Speepay. (Bowerbank.)

NISI. [Rule (in Law). P. C.]

NITELLA, a genus of plants belonging to the natural order Characeae. It is characterised by the whole plant being more or less pulvillus; the cells are tubular, not invested with a secondary layer of smaller cells as in Chara; the reproductive organs consist of globules and mucous, mostly sealed on the terminal whorl and axillary.

Four species of this genus have been described inhabiting Great Britain.

N. nitidus has an elongated filicid pulvillus glossy stem, with the branches of the whorls spreading, elongated; the mucous and globules approximate, on the smaller ruellia scarcely bracteate. It grows in deep and stagnant ponds, but is by no means common. It is found in Great Britain, and is the largest or the largest of the British species, and best adapted for the examination of the curious currents, which are obvious in the whole of the family to which it belongs. [Sar., P. C.]

N. flexilius has a stem one to two feet long, smooth, flaccid, somewhat glossy and pulvillus. It is not infrequent in lakes and still waters. The mucous are often solitary. The stem, like that of Chara, is often incrusted with carbonate of lime. Hassall thinks this constitutes the only distinction of Agardh's N. opaca.

N. nitidus has single stems, smooth below, flaccid, somewhat glossy and pulvillus: the mucous and globules separate. It is a native of the salt water ditches in the south and east of England.

N. gracilius has smooth, glossy, pulvillus stems, with whorls of the branches compound, the segments acute, the branches angular, one or few, deltate and compact species, but probably not distinct from N. flexilius. In fact, it may be questioned whether all these species are not varieties of one.

(Hassall, Freshwater algae; Smith, English Botany.)

NOD AND LINES. The former are those points in the length of a string extended between two fixed objects, or in a column of air confined at one end and at another extremity, when the string or column is put in a state of vibration. They are as to remain at rest and the latter as corresponding lines which exist on the surface of an elastic body, usually a plate, whose parts are in a state of vibration.

It is well known if a string or a metallic cord be attached to its extremities to a board or plate, on causing it, when in a state of tension, to vibrate transversely, there may be distinguished, besides the principal sound, which is due to the length of the string, several others which have a greater or less degree of respective height, and are generally ascribed to the thicker, or thinner, or more or less thick of the air, and are conceived to result from some property of the extended string, by which, when in a state of vibration, it becomes a sort of moving axis, having on it points, at distances from one another in the proportions of the whole length of the string, at which points a contrary in the directions of the vibrations of the string the latter in a state of rest. Such are called nodal points; and they may be considered as the centres of attraction or repulsion in the thickness or density of the string, or of different degrees of flexibility in its different parts. The string between every two such points is in the same condition as if it were composed of two separate strings, whose vibrations are consequently such as are due to the distance between the points, and hence arise the secondary or harmonic sounds.

A string of considerable length, on being made to vibrate, will be found to have several such nodal points, and the curves which the intervals assume in consequence of the vibrations, though alternately on opposite sides of the axis of the string, are equal and similar to one another. The situations of the nodal points may be made evident by placing, at intervals, across the string, pieces of paper notched or bent in the form of an inverted V; those which are at the places of nodes remain motionless, while the others experience agitations, or are thrown entirely off.

If a string, in a state of tension, have its extremities attached to a board or a plate of metal, and be made in some part of the string into a circle, or a semicircle, or a longer length, the string, if it be not bent, the vibrations of the string, when a violin-string is drawn across it, will be communicated to the plate; and if over the latter light dust be strewed, that dust will be agitated and made to arrange itself on lines at which the surfaces of the plate is in a state of rest: these are called nodal lines, and the figures which they form are called Acoustic figures. Again, if a glass rod be cemented at one end to the centre of the plate, or the like metallic, and be communicated, for example, with a wet cloth, so as to be put in a state of vibration longitudinally, those vibrations will be communicated to the dust, and light dust strewed over the latter when in a horizontal position will arrange itself in acoustic figures. Or, if a glass rod be connected at each extremity to a glass disk at right angles to its length, on exciting one of the disks by drawing a violin-string across its edge, the vibrations of that disk will, by means of the rod, be communicated to the other; and if light dust be strewed over both it will arrange itself in figures: when the dusts are equal and similar to one another, the figures will be similar both; otherwise there will be a difference.

If a column of air in a cylindrical tube which is closed at either, or at each end be acted upon by the force of the breath, for example, applied at an aperture in any part of its length; it will assume a state of equilibrio. It is the largest of the British species, and best adapted for the examination of the curious currents, which are obvious in the whole of the family to which it belongs. [Sar., P. C.]

VIBRATION, P. C.]: those portions are separated from one another by sectional areas in which the particles are at rest; the condensations, or rarefactions, of the air being, in those areas, greater than in any other parts of the tube in consequence of the particles moving in contrary directions, and with equal velocities towards, or from, them. Such areas are called nodal sections, and several may exist at the same time in the tube. Their existence is rendered evident by boring small holes in different parts of the sides of the tube and covering them with pieces of thin paper slightly adherent to the sides of the tube, when the particles in the nodal sections become slightly agitated, while, in the intervals, they will be greatly agitated.

If, in the side of a tube containing a column of vibrating air, any aperture exist by which that air is enabled to communicate with the atmosphere, the air in that section becomes in equilibrio with the latter, and, in that section, there is consequently neither condensation nor rarefaction: this section corresponds to the middle points between two nodes in a vibrating string.
found to take place parallel to the surface, and other perpendicular to it: the former being called tangential, and the latter normal vibrations. In one case the particles of dust glide upon the surface in directions which tend alternately towards and from the nodal lines (the movements in the former direction being always more rapid than those in the other, till they come to a state of rest on those lines: in the other case the particles alternately rise from and fall back upon the surface at the places where the latter is in a state of vibration; and, dispersing from those places, they become quiescent in the lines of no vibration.

Galileo was the first who observed ("Dialoghi della Scienza Nuova") that the vibrations of plates might render audible the vibration of solids. He therefore remarked that the sand became accumulated at the parts where the vibrating plate was in a state of rest: but this subject was extensively investigated by Dr. Chladni of Wittenberg, who first discovered the longitudinal vibrations of solid bodies; and, in 1787, published, in a work entitled "Entdeckungen über die Theorie des Klanges," an account of numerous experiments which he had made on the nature of the vibrations produced in plates of glass of different forms.

The plates with which such experiments may be performed should be of good window glass; and, if square, from 4 to 8 inches on each side; if circular, their diameters may be within the same limits. In making experiments on the plate, it must be held horizontally between a finger and thumb, or it may be fixed within the lips of a clamp screw; and when it is required to prevent any particular part of the plate from vibrating, that part, if on the edge, may be pressed against a fixed object, or, if at any part of the surface, one of the fingers of the hand may be pressed gently upon that part. The plate being in a horizontal position, it must be covered with a layer of sawdust; and it may be set in a state of vibration by drawing a violin-bow across its edge: the dust will then arrange itself in figures which will vary with the form of the plate, the place at which the bow is applied, and that at which the plate is held, up to a square plate held at its centre, and the bow be applied near one of the angles, the dust will arrange itself in lines so as to divide the plate into four equal squares (No. 1). If the plate be held as before, and the bow be applied at the middle of one of the sides, the vibrations will be such as to make the dust lie in the direction of the two diagonals (No. 2). Again, if the plate be held at A (No. 3) and the bow be applied at B, the dust will assume the positions of the three lines parallel to one another; and if the plate be held at a point near the edge, the lines will become curves, as in No. 4.

If a circular plate, held at the centre, be pressed against a fixed object at any point on its circumference, and the bow be applied at 45 degrees from that point, the lines will take the positions of two diameters at right angles to one another, one of them passing through the point at which the circumference touches the object. A greater number of radiating lines than four will be produced if the bow be drawn more rapidly with less pressure against the edge of the plate than in the former case. If the centre of the circular plate be free, various curve lines will be assumed by the dust, according to the position of the point which is held; and one of them is represented in No. 5. The figures represented in Nos. 6, 7, and 8, are selected from the great number which Chladni has obtained with glass plates of a circular, a polygonal, and a triangular form.

M. Felix Savart, has observed, that, if a rectangular plate of glass be held at one point, with its edges, and is sufficiently thick, be held horizontally between a finger and thumb at the middle of its opposite edges, and it be put in a state of longi-

tudinal vibration, either by rubbing its under side, near one of the ends, with a wet cloth, or by striking it gently at one end, the dust on the upper surface will arrange itself in lines perpendicular to the length of the rod. It is remarkable, that if the plate be turned with its upper face downwards, being held as before, the dust which falls on it, and rises from the points of contact, will be dispersed in the manner described above, the places of the nodal lines will be opposite to the middle of the intervals between the lines observed in the other position of the plate; Chladni's experiments prove that the motions of the particles in the one half of the thickness of the lamina of glass are directly contrary to those in the other half. A like effect has been observed when cylindrical plates of glass have been made to vibrate longitudinally; the lines of nodes then take a spiral form about the thumb and finger, and the curves consisting of portions which run alternately in contrary directions: the points of greatest and least inclination to the axis of the cylinder are at 80 degrees from each other with respect to a line drawn on the surface parallel to the axis, and the effect is such as would arise if the cylinder were divided longitudinally into four quadrant portions, having opposite qualities. The places of the nodes on one part of the rod which was uppermost were found, the rod being held in a horizontal position, by annular pieces of paper loosely encircling it.

In 1822, M. Berthelot read to the Académie des Sciences at Paris, an account of some curious experiments in which acoustical figures were produced in consequence of vibrations communicated through the air to elastic membranes. (Browsee's Edinburgh Journal of Science, vol. ii. p. 298.) A sheet of this paper was held at the centre of a circular plate of glass, four or five inches in diameter, and on it was strewn light dust. A thin circular plate of glass, in a state of vibration, was then brought within a few inches of the paper, when the vibrations were communicated to the latter, and, the paper being of uniform thickness and well stretched, the dust assumed figures which were perfectly regular. M. Savart, having rendered the glass plate immovable at opposite points on its circumference by holding it at the thumb and a finger of each hand, placed the tip of another finger at a point on the surface, at a distance from the centre equal to about one-fifth of the diameter, and caused the plate to vibrate drawing a violin-bow across its circumference. In these circumstances, on presenting the plate to the stamped paper, the following appearances were observed. The nodal figures on square paper were analogous to those formed on a square plate of glass or metal, and on circular plates their general character was circular. The circular lines were sometimes cut by diametrical lines which formed nodal points, or stars, and the number of these increased with the acuteness of the sound produced by the bow. When the plate of glass was parallel to the paper, the nodal lines were similar on both, as when two plates were connected with each other, by a rod fixed perpendiculariy between them. If the glass plate was held vertically, the nodal lines on the paper became parallel to one another; and the figures on the paper changed as the glass plate was made to decline from the vertical position.

NODIER, CHARLES, was born at Besançon, in France, on the 29th of April, 1780. Under the care of his father, a man of stern principles and of a cultivated mind, he evinced in early life a considerable disposition for the acquirement of knowledge. At the age of twelve he entered on a course of classical study, which was, however, soon interrupted by the events of the Revolution, the principles of which his father, at that time mayor of Besançon, warmly espoused. During the Reign of Terror young Nodier obeyed the call of his country to poetry and composing tragedies on classical subjects. These early compositions he was accustomed to read to an aged friend, who judiciously advised him to devote himself to serious pursuits. The beneficial consequences of his advice became manifest, when, five years afterwards he published a work of considerable research and great critical acumen, entitled "Le Dictionnaire des Oubliettes," a curious dissertation on words which derive their signification directly from the action which they represent (souper, 'a name,' and soupe, to make), as the verb to hiss in our language, and is inferior in style to any of his later productions. During the same period of the Reign of Terror he formed an
acquaintance which terminated in the most intimate friendship with Mons. de Chantrast, a Royalist officer, who was compelled to seek for safety in a retired country-life; through his exertions Dôle had been enabled to solicit the natural history of which he afterwards devoted a considerable portion of his time; it was especially to the minute examination of insects and flowers that he was attached, and his taste for them is strongly marked by his after-product. In 1796 he published the result of his studies in a dissertation on the organs of hearing in insects, and in 1801 in a small work entitled 'Bibliothèque Entomologique.' In 1796 Nodier went to Paris, where, furnished with the munificence of his countrymen, he was admitted into the best literary societies of that time. Two years afterwards he retired to his native town; but soon becoming wearied of the monotony of a provincial life, he sought for novelty in the society of the poltroons and sceptics, and became a regular contributor to the 'Journal des Débats.' A short interruption to his residence at Paris was caused by the acceptance of the office of librarian at Lévis in Lorraine, with the promise of a salary of 500 francs in return for his services to the public. In 1809 he was elected a member of the Academy. His first important writing was the 'Contes de la Salle de Justice,' which appeared in 1811. The book was a complete overthrow of the political system of the Bourbon dynasty. It was pronounced, and was so considered by the French government, that it was prohibited from being read. The work composed the necessity of providing for the subsistence of his family obliged him to abandon the charms of a country life in order to settle in Paris. Previous to leaving Dôle he contributed to the journal 'Le Moniteur de Dôle,' which appeared every week, the history of the town, to which it was attached the small salary of 1000 fr., about 40l. a year, but the corporation, with a regular want of discernment, had refused it to him. In Paris he published a military history of the war in Lorraine, and composed, in 1812, 'Lettres de la Salle de Justice.' The next year he published the second volume of the same work, and under the name of 'Monsieur Nodier,' continued to contribute to the 'Journal des Débats.'

Nodier's early literary life was marked by great activity. He published in 1815 the first volume of a work which he intended to be a complete history of the French revolution. In 1816 he published his 'Vie du général Drouet,' and in 1817 his 'Histoire des Passions.' He also published a work on the history of the French revolution, and a work on the history of the French republic. In 1818 he published a work on the history of the French revolution, and a work on the history of the French republic.

Nodier's literary career was marked by great activity. He published in 1815 the first volume of a work which he intended to be a complete history of the French revolution. NOLNA (so named by Linnaeus, from nola, a little boat, like the bulbs of lilies, and nolani, the tribe Nolanae.) is a genus of plants belonging to the natural order Solanaceae and the tribe Nolanae. It has a 6-angled calyx, a campanulate 6-lobed 6-locular corolla; 5 stamens adhering to the tube of the ovary; 5 ovules in each cell, adhering at lengthwise. The seeds are roundish, with a membranous testa, and showy copious albumen. The species are herbs, native of Peru and Chili, usually annual. Leaves alternate, quite small; the flowers are solitary, pedunculate, and of a showy blue colour.

N. prostrata, prostrate Nolina, has a prostrate stem, ovate oblong leaves, a pyramidal calyx, with triangularly sagittate acuminate tips, about three-eighths an inch in length, and a few flowers at the top, but none on the stem. It is a native of Peru, but grows freely in this country in the open air. In France poetry is fed upon it, and it is so fond of it that Peronoon proposed to call it N. gallinaeosa.

N. paradisiaca has prostrate hairy stems, ovate oblong pilose leaves, the segments of the calyx triangular, the corolla campanulately funnel-shaped, the drupelets cumulated, 1-seeded. It is native of Chili, on the sea-shore about Concepcion. The flowers are blue.

The species of Nolina are only valuable as ornamental plants; they are showy when in blossom, and are much used as some of the trailing species of Convolvulus. The seeds should be sown in spring, and the plants when of sufficient size or about the middle of May should be finally transplanted to the open ground, where they will flower and ripen seed; or the seeds may be sown at once in the open ground in September (Doce's Gardener's Dictionary; Barnett's Outlines of Botany).

NOLLET, JEAN ANTOINE, a distinguished French philosopher, was born at Paris, in the year 1705. In 1733 being the intention of his father, who held a farm in that part of France, that he should embrace the ecclesiastical profession, he was sent to the college of Beauvais, in order that he might prosecute the study of theology; but his taste inclining him to cultivate the physical sciences the intention was abandoned, and he was never afterwards connected with the church but by holding deacon's orders with the title of Abbé. On leaving the college he went to Paris, where he attended a course of lectures on natural philosophy, the subjects of which he studied with great diligence, repeating in his humble dwelling the experiments which he had seen performed in public. He possessed many of his leisure hours in the practice of enamelling; and he is said, at one time, to have superseded the education of a son of M. Talbot, who held the post of recordar.

Nollet felt himself particularly, in conjunction with M. Dufay, to the subject of electricity; and he soon became distinguished by the number as well as the ingenuity of his experiments with relation to that science, performing those which have been considered the most important, and induced him to make use of his valuable apparatus. He was the first who observed that pointed bodies, when electrified, give out streams of light, but did not exhibit in other respects much greater effects than those which had before been observed on blunt bodies; and he found that the smoke of burnt linen and wood, and the vapour of water, were better conductors of electricity than the smoke of gun-lac, turpentine, or sulphur.

He ascertained that an excited tube lost none of its electricity by being placed in the focus of a concave mirror when the sun's light was concentrated in that point; that glass and other non-conductors were more strongly excited in the air than in vacuo; and that all of tarrying on a wooden wheel was capable of producing the electric fluid in abundance: he observed also the diffusion of the electric light in vacuo. He discovered that electricity augments the natural evaporation of fluids, and that the effect is the greatest when the fluids are contained in non-electrical vessels.

In repeating the experiments of M. Bozzi on the effects of electricity in promoting the discharge of fluids through tubes, Nollet found that no acceleration took place when the bore of the tube exceeded 1/16 of an inch in diameter; he ascertained however that if the bore was very small the electrified fluid divided into several streams and acquired considerable velocity, preserving its direction. He observed that the experiment was performed in the dark. He electrified, during several days, the mould in a garden pot, in which seeds had been sown, continuing the operation three or four hours each day; when it appeared to have ripened the plants and shoots earlier than the plants obtained from the like seed in a pot containing the same kind of mould, but which was not electrified. Nollet also performed an experiment on a large number of plants, the flowers of which were similarly affected, and he imagined that the animals were lighter than those of the same kind which were not so treated: from hence he concluded that electricity increases the insensible percolation of sap out of leaves, and it will be found in the Philosophical Transactions for 1748; but it ought to be observed that experiments relating to the effects of electricity on plants and animals have, since, been frequently repeated without verifying the conclusions of the French philosopher; and it may be added, that the attempts which have recently been made to promote the growth of vegetables by an apparatus for conveying to the ground the electric fluid in the atmosphere, have been entirely failures.

In 1734 the Abbé Nollet, accompanied by his friend M. Dufay, made a visit to England, when he was elected a Fellow of the Royal Society of London: he went from hence to Holland for the purpose of conversing with the philosophers of that country; and, on his return to Paris, he delivered a course of lectures on physics, which was well attended. In 1739 he was elected a member of the Académie des Sciences; and, during the same year, he went to Turin, where he repeated his electrical experiments in the presence of the Duke of Savoy. In 1742 he was invited to Bordeaux, where he delivered a course of lectures; and he was credited with having discovered the presence of the dauphin of France, the son of Louis XV.

Nollet made many experiments to ascertain, at various depths under water, the intensity of sounds excited in the air; and he performed others on the structure and consists of a hunter's horn were heard distinctly, but very faintly, at two feet below the surface. He was not fortunate however in his hypothesis concerning the nature of the electric fluid; he imagined that this fluid had two motions, viz., an affinity to the electric body and an efflux from it, and he supposed that, in consequence of the former, all light bodies are attracted or carried towards the electric; while, in consequence of the latter, they repelled by it. Hence he considered that all bodies have two different kinds of pores, one kind for receiving and the other for emitting the electric fluid. This hypothesis has never been admitted by philosophers.

In 1747 Signor Fischi, of Venice, published a pamphlet in which it was stated, that a man who had suffered from a pain in his side had by him been cured on being electrified with a machine in the glass cylinder of which was contained some balsam of Peru; and that two persons of great age had been cured of the gout by the like means: the benefit was supposed to have arisen from the effluvium of the balsam, which had been electrified.

In 1748 he was stated to be in bed with a fever; and he was apartment of one of the patients who had received it was strongly perfumed with it. Professor Winkler of Leipzig also stated, about the same time, that he had performed similar experiments on the smell of cloves, thyme, sweet bay, bay, and phur or emonored enclosed in the globe of the machine. These extraordinary reports induced the Abbé Nollet to make a journey to Italy for the purpose of obtaining information respecting the nature of the experiments; and the result of his inquiry was that, though in some cases the patients might find relief from electricity, its effects had been greatly exaggerated. All attempts in England to obtain results corresponding to those which were said to have been produced on the continent entirely failed; and the reports of the pretended cures soon ceased to obtain credit.

In 1756 the king of France founded a chair of experimental philosophy at the college of Navarre, and he appointed the Abbé Nollet to superintend it; the zeal and ability with which the latter fulfilled the duties of his post gave full satisfaction to the king, who conferred on him the title of Master of Philosophy and Natural History to the Royal Family.

Nollet was subsequently appointed Professor of Experimental Philosophy to the School for Artillery, which then existed at La Fère, and which was afterwards removed to Meudon.

He died April 24, 1770, in the Louvre, where the king had assigned to him a suite of apartments; the amability of his character was equal to his talents; and it is said that he devoted nearly all the profits of his labours to the support of the poor.

Best known is the Royal Society of London and a Member of the Académie des Sciences at Paris, he was a Member of the Institut of Bologna and of the Académie d'Érlog.
NOR FOLK ISLAND PINE. [Araucaria; P. C.]

NORMANDY, CUSTOMARY LAW OF.

In 1668, the Most King of France divided his dominions into provinces, and all then appearing in the All tourists to the province which was the chief place of the canton of Gravelines. The town has some historical interest from the defeat of the French in A.D. 1668 under the Duke of Berwick, and the French were assisted by some English ships that were off the coast.

The town was situated in the region of the present-day town of Gravelines, which is a church, a nursery, a military hospital and barracks. The population of the town is approximately 4,419; by that of 1866, 4,462. It is the chief place of the canton of Gravelines. The town has some historical interest from the defeat of the French in A.D. 1668 under the Duke of Berwick, and the French were assisted by some English ships that were off the coast.

The modern or reformed 'Coutumier de Normandie' is revised into 34 chapters, which are subdivided into 523 articles, as Rouen on 1st July, 1585, by commissioners appointed by Henry III. of France with the concurrence of the provincial authorities known as 'les gens des trois états,' or three orders representing the nobility, the clergy, and the bourgeoisie.

Among the peculiar customs of Normandy was 'la clameur de Haro,' which custom still prevails in the Channel Islands, where the Norman ancient custom is the principal law. [Alençon, P. C., and C. B., Jany, p. 46.]

The 'Clameur de Haro' may be denominated a call upon the supreme authority for justice, 'appelation ad principem ad opem in lite ferendam.' The term is considered to be derived from Duke Rolle, as the name is variously spelt, Rou, Rou, and Roux, to whom Normandy was ceded by Charles the Simple of France, in 919. (Du Moulin's Hist. de Normandie, lib. i. c. 2, and ib. vol. exp. 20.) So that 'Haro' is a corruption of the cry Hal, or La Roux, by which this prince, who was re-markable for his justice, is said to have been invoked. It is thus practised in the Channel Islands: when an individual considers that another is making a trespass, or is infringing upon the rights of another, he applies to two witnesses, who protest against the proceedings, and, crying out three times 'Haro,' in the queen's name summons the trespasser to desist. He then applies to the judicial authorities, declaring what is termed 'une censure,' an examination by the court of all the circumstances of the case; be afterwards brings an action against the trespasser. If he neglect to do so, then the person against whom the 'Haro' was cried may bring his action against him, who cried it, and oblige him, if he cannot justify his proceedings, to desist and submit to the judgment of the court. Upon the action of either of the parties the decision is generally referred to what is termed 'une instance,' an examination by the court of all the circumstances of the spot itself.

Whichever of the parties is condemned, he is subjected to a small fine to the queen and pays all costs; in addition to which he was formerly liable to be 'tied by law,' that is, 'gard de château,' that is, twenty-four hours' imprisonment; the impounding of the goods on the principle of causation and the invasion of another's possession being accounted equally criminal. In ancient Normandy parties resorted to the 'Clameur de Haro' in cases of assault and battery, but that part of the custom has never prevailed in the Channel Islands.

The president or chief judicial officer in Guernsey is still styled bailiff, the name by which he is designated in the ancient 'Coutumier de Normandie.' In Jersey he is styled bailey, by which name he is designated in the modern custom of the same island. In Alderney this officer is styled bailey, by which name he is designated in the Channel Islands. The minister or his deputy is the grand bailey, an officer whose authority is of the same nature as the bailiff, and is his superior. The bailiff has a bailey, a bailey officer, in each of the parishes, wherein it is stated that the bailey is intrusted by the prince or the bailiff himself to manage the different matters depending on him, and that he is responsible to the superior for the manner in which he discharges his duties. It is his duty to maintain order, to decide according to law and usage all disputes arising between parties residing within his jurisdiction; and to put down all thieves, incendiaries, and other malfeasors.

It was remarked at the commencement of this article that the different provincial customaries had been frequently commented upon. The first commentary on the Grand Coutumier of Normandy was written by Rouillé, a jurist of Alençon. (Guillaume de Rouillé, Commentaire sur la Coutume de Normandie, fol., 1584, reprinted in 1598.) It was followed by that of Terriére de Dieppe, which was published in 1744, after his death. (Guillaume Terriére, Commentaire sur les Coutumes civi- ciennes de Normandie, fol.) The former is more generally received as an authority in Jersey, and the latter in Guernsey. These commentaries, though they have not given to their au-thors the reputation of a Bourbon, the president of the par-lament of Brittany, or the Arzégaud de Brittany, were held in high authority by the parliament of Rouen. After the revision of the customary in 1585, several modern commentaries were made of Bérenger, Sebag, Godofrey, Fauët, Fausse, and Howard. That last-named commentator has, at the end of the fourth volume of a work entitled 'Dictionnaire Analytique, etc., de la Coutume de Normandie,' issued in 1782, published, we believe,

for the first time, from a manuscript lent him by the Marquis de Paulyn, a poetical version of the customary of Normandy. Several manuscripts of this poem then existed; in one of them there was the following prologue, which, if authentic, determines its date and the name of its author:

'Mait Dieu nous en grant bien vouloir, 1782
Après ce que Jésus Christ vient
Et temps houard lémosigné
Pour rendre nos monsitieus,
Es moynt ses peopleus.
He' Adam noss tolitz julis,
Quest monde versis for yrs;
Mit Richard Doubrueu les livre
En rhime en meeus qui petit
Per les moult gens de son art le plus.

There appear however at the end of the MS. of the Marquis de Paulyn, which did not contain the above prologue, the following lines:

'Quel mon nom vuait apprevend'
La sigilleg et pour ne voie,
Oli et me C, A, P, H, P.'

This interesting relic of ancient poetry is of considerable length, and is divided into 147 chapters; the language and details afford internal evidence of its having been composed in the thirteenth century.

The following definition of 'coutumes' may be taken as a specimen of that which the author has given:

'coutumes ce sont ceux usages
Approprées par les Princes seignes,
Incendiaries gens qui ont fait ou commis,
Ces qu'on s'y doit tolérer;
Des autres feux de la main
Des autrui droits et souverainets;
Des droits qui vient d'e'tats,
Et des coutumes, sont ces ues,
Receptacles, autrui communes.'

CHAP. IV.

The following are the best editions of writers on the subject of the Coutume de Normandie:

— Décisions sur chaque article de la Coutume de Normandie, et observations sur les usages locaux de la même Coutume par Pierre de Mervielle, Paris, 1731, fol.; Béraud, Josias, an advocate of the parlia-ment of Rouen, born 1658, died 1699; Commentaire sur la Coutume de Normandie, Rouen, 1814, in fol.; Bérenger, Henri, born 1616, died 1655; Commentaire sur la Coutume de Normandie, Rouen, 1787-1818; Godofrey, Françoise, 'Coutume du Pays et Duché de Normandie avec les Commen-taires de Béraud, Godofrey et d'Aviron,' Rouen, 1864, 2 vols. fol.; Fauët, Jean Bapiste, born 1711, died 1783; Explication de la Jurisprudence et de la Coutume de Normandie, 2 vols. fol.; Fausse, Coutume de Normandie avec les observations de Roppe,' Rouen, 1759, In 4to.; Howard, David, born 1726, died 1803; Traité sur les Coutumes Anglo-Normandes, Rouen, 1778, 4 vols. fol.

Hale, in his 'Decisions of the Common Law of England' (chap. vi.), maintains that the 'Coutumier de Normandie' was written long after Glanvill's tract, which was written in Henry the Second's time; and that the Norman collection was made after the time of Hale. He appears to have accepted this notion of his coronation, and appointing it for the limitation of actions ancestral, which must at least have been thirty years after. Nay, the 'Coutumier' appears to have been made after the act of settlement of Normandy in the crown of France, for therein is specified the institution of Philip king of France, for appointing the coronation of Richard I. for the limitation of actions, which was after the said Philip's full possession of Normandy.' Hale's opinion is, that 'this similitude of the laws of England and Normandy was not by confirmation of the laws of England to those of Normandy, but by confirmation of the laws of England to Normandy.'

NORONHA, FERNANDO DE, a small group of islands, belonging to Brazil, and situated in the Atlantic Ocean. The fort Concepción on the principal island is situated 32° 50' N. lat. and 32° 26' W. long. The group consists of two islands of moderate size, Fernando de Noronha and Dos Rotes. The soil is stony, and there are only a few small spots susceptible of cultivation. As there is no harbour, and the surf runs high on its shores, landing is difficult and sometimes dangerous. It has good water. The islets of the group are however too high to board the vessels, which visit this island for a supply, on account of the surf. To the north, and separated from it by
a narrow channel, is the Islad des Ratas (of the rats), which is three miles long, less steep and more wooded. These islands are used by the Brazilian government as a place of deporta-
tion, and containers amounts to about eight hundred, and the Garrison consists of two hundred black soldiers. They cultivate a small
quantity of mandor, a few fruits, and a little corn, and keep some domestic fowls. That island enjoys the same advantages as the other islands, and the sea-birds of which they are fertile
houses, are numerous. No boats are kept on the island, and no intercourse is held with shipping, without permission and the strictest in-
structions.

(Henderson’s History of the Brazil; Narrative of the Sur-
veying Voyages of the Adventure and Beagle.)

NORTH, SIR THOMAS, Knight. We regret that we have not a single line relating to Sir Thomas North, a biographical notice of Sir Thomas North, the first translator of the Lives of Plutarch into English. North had previously published two other works—1. The Diaries of Prince; compiled by the Reverend Father in God, Dom Anthony de Guaram, and
Engheshed out of the Frenche; right necessary and pleasant to all gentlemen and others which are lovers of vertue,
London, 1547, folio, 1559, folio, 1569, 4to. 2. Referr’d
of faults in the first edition, with an amplification also of a fourth book annexed to the same, entitled the Favoured Courtier; never heretofore in our vulgar tongue; right necessary and pleasant to all noble and vertuous persons.
3. The Most Philosophical Discoveries of the several
sancient writers; a work first compiled in the Indian Tongue, and afterwards reduced into divers other Languages; and now
lastly Engheshed out of the Indian, London, 1570, 4to. Wat
observes in his preface, Dom Doni was so insensible of the in-
that of Magi, a strange blender of the learned bibliographer.
Doni is the name of an old Italian writer, and the original
work is called La Filosofia Morale del Doni, treatt’d stag-
children of the earth, or, Amyot’s writ, Amyot,
scrivta da Sedebard, morassimo Filosofo Italiano, Venice,
1532, 4to.

North’s translation of Plutarch was made, as he states in the title, from the French version of Amyot, which is gene-
really very exact, and has considerable merit in point of ex-
Indeed it is said that Amyot’s translations did much towards raising the French language. Amyot’s dedicat-
Henry II. of France is dated 1545. North’s dedication to
Queen Elizabeth is dated January 6th, 1579; his address to the
Reader is dated January 34th, 1579. North’s version is
can anyone, that of Amyot’s is correct, which is somewhat
strange, for he tells us that he translated Amyot. The
book, besides the Lives of Plutarch, contains The Lives
Epaminondas, of Philip of Macedon, of Dionysius the
conquered, of Numa Augustus; and The Lives of
Authors; also The Lives of Nine excellent Chieftains of
Warre, taken out of Latine from Eusebius Probus, by S. G. S.,
by whom also are added the Lives of Plutarch and of Seneca;
good, and considerable. These works have now been translated into English by Sir Thomas North, Knight.
This part of his book is also dedicated by North to Queen
Elizabeth, to whom he seems to have been indebted for some kind
or kind of assistance, as he says, ‘The princely bounty of your blessed hand (most gracious Sover-
igns), comforting and supporting my poor old decaying life, of
right challenging the travel of my study, the labor of my
body, and the prayers of my devotion, to be wholly employed for your Highness, and altogether dedicated to your service.’
(Watts’s Bibliotheca Britannica; Biographia Universelle, article Doni.

NOBLE FRANCIS, BARON GUILDFORD, lord
keeper of the great seal of England, the immediate elder brother of the following, was born, as Lord Campbell has
discovered from the inscription on his tomb-stone, on the 22d of
October 1643, and was acquired the Master of arts at Christ-Colledge, at school at Laleworth, where he appears to have been taught some rigor Presbyterian principles, which left very little trace on his mind in subsequent life. In 1648 he was
admitted a Fellow of King’s College, and was afterwards a master of St. John’s College.
He afterwards became a member of the Middle Temple. He
passed his time gravely and studiously, and appears early to have resolved not to leave any plan untried, whether by intellect, by eloquence, by presump’tion, by wealth, power, and distinction. His relaxation consisted of music meetings, hearing Hugh Peters preach, and occasional convivial suppers with fellow-students—very small items of dissipation, the nature of the times and the habits of the young
lawyers of the Restoration considered. He was well-con-
connected, and received some aid and assistance from his relatives
in his early struggles. His practice however was for some
years at this time, and probably in disfavour among learned men;
or rather in so much despis’d when he was taken in hand by Sir Jeffrey Palme, the attorney-general, who in the character of the young barrister something for which the crown lawyers of such
quality as Dr. Selden, Dr. Leland, and others, in the reign of
WILLIAM and MARY, were in some measure degraded, and the
propriety and usefulness of the practice of the law in the hands
of men, and when none would starve with him in journeys, this
young gentleman kept him company. The memoir of the
lord keeper by his brother, Roger North, is one of the most
ample developments of private life and habits during the
seventeenth century which our literature possesses. We are
let into all the hopes and fears of the young aspirant—his
paltry and dishonest tricks, his insatiable selfishness, his moral
cowardice, his trimming politics, and his readiness to do any
work that persons well intrenched in power might set before
him. The book is all the more curious because its author
interests these qualities as prudential virtues, and exhibits them
as that which the French called the honest gentleman, or the
character that Lord Campbell seems rather disproportionate when the nature of the times is considered. The
brother is particularly instructive in describing his at-
tempts to obtain a rich office, by making hearty commendations
on the skill and intrepidity with which he followed every effort
to ally him to anything under the desired standard of wealth.
Other publications appear not to have given him much con-
cern. One curious communication is a recommendation to
him a recommendation of a lady, who was only daughter of
an old usher of Gray’s Inn, supposed to be a good fortune
in present, for her father was rich but, after his death, to be
worth nobody could tell what. His lordship got a sight of
the lady, and did not dislike her: thenceupon he made the old
man a visit, and a proposal of himself to marry his daughter.
There appeared no symptoms of discouragement; but only
the old gentleman asked him what he intended to settle on his father—intended to settle upon him for present maintenance, justitute, and pro-
vision for children. This was an insauspicious question, for
the young gentleman was placed in his father’s office, and
ship, and some would be to spare for him. Therefore he said
to his worship only ‘that when he would be pleased to declare
what portion he intended to give his daughter, he would
write him again.’ This was the answer of the old gentleman.
And so they parted, and his lordship was glad of his escape,
and resolved to give that affair a final discharge, and never to
come near the terrible old fellow any more. His lordship
had at that time a stout heart, and could not digest the being
so slighted, as if, in his present state, a profitable profession
and future hopes were of no account. If he had had a real
estate to settle, he should not have stopped so low as to match
with his daughter; and thereforeforth despised his alliance.’
He brought himself into notice at court by pleading against
the privileges of parliament in the Writ of Error brought
into the House of Lords upon the judgment of the King’s
Bench in favor of the possessors of the preeminence in that
for holding the Speaker in the chair. On this occasion he
was rewarded with a silk gown. On the 20th of May, 1674,
he was made solicitor-general; and on the promotion of Sir
Sampson Heath, he was made the Attorney General on the 13th of November, 1678. On the 20th of January, 1676, he was made lord chief justice of the Com-
mon Pleas. This was at the period of the curious disputes
in the Court of Chancery between the King’s Bench and the
King’s Bench, founded on no higher motive than the fees
paid by the litigants. The King’s Bench had engrossed so
much business by the fictitious use of the writ of ‘arrantis,’ that
this was the principal cause of enmity; and the possessors of
their coming to Westminster Hall every day in the term. North retaliated by a dexterous use of the ‘capias,’ and
we are told that after this process came into common use, it is scarce to be conceived how the court revived and
flourished, being, instead of vacation in term, rather term in vacation; so large was the increase of trials by mist primus out of the court, as also of motions and pleas in the court. These struggles are well known to have had great influence in the practical extension of the jurisdiction of the three courts of the crown. It was bound to play a large part in the judicial reform.

On the death of Lord Nottingham, the great seal was con

NORTH, ROGER, the third son of Dudley, Lord North, was born about 1740; he was not a man to be easily dazzled to lose sight of his own ultimate interest. Knowing that, from the difficulty felt by the king in obtaining parliamentary supplies, it was intended that the new lord keeper, Lord North, should be his instrument, and conscious that he was the only person who had at that juncture a substantial claim on the appointment, he refused to touch the seal, until, for his majesty's honour, they were accompanied by a pension of 2000L. a year. As a judge, he was almost invariably in favour of the prerogative, and seldom if ever endangered his influence at court by his independence. A bold and still less scrupulous instrument of power was however gradually undermining him in his latter days in the person of Jeffreys, whose ascendency and presumption seem to have completely broken the spirit of the lord keeper. He kept a sharp look out for having attempts to militate against the cruel acts of Jeffreys's campaign; and Lord Campbell, in a comparison of dates, finds that the lord keeper's death occurred at too early a period in the history of the massacre to be of his instrument. He died on the 9th of September, 1665. He wrote in his private life, a moral man even for an ordinary age, and a miracle in the reign of Charles II. On his professional merits, Lord Campbell says, he had made as much law as he could contain, but he was incapable of taking an enlarged and commanding view of any subject.'

(North's Lives of the Norths; Campbell, Lives of the Glouchesters, III. 449.)

NORTH, SIR DUDLEY, the third son of Dudley, Lord North, Baron of Kelting, was born on 16th May 1641. In childhood he was lively and active, and having strayed from hall exercises, spent a young age in giggling and prattling, with the additional sin of being a wild boy, and with difficulty recovered. He made little progress in literary education, and his brother and biographer tells us that he ' had a strange bent to traffic, and while he was at school, drove a subtle trade among the boys by buying and selling. In short, it was considered that he had learning enough for a merchant, but not phlegm enough for any sedentary profession; which judgment of him was made good by the event.' Being ' bond to a Turkey merchant upon the ordinary terms to be sent abroad,' he was sent as supercargo to Archangel and Smyrna. He left an animated and curious journal of his voyage to Archangel, and his subsequent progress by Italy to Smyrna, which is full of interesting characters, and suggests remarks. After a residence for some time in Smyrna, where he suffered from disease, he removed to a factory at Constantinople under King Charles II., and kept the King informed, which he said 'that for scolding and railing it was more apt than any other language.' He left some curious information about Turkish manners, particularly as to the administration of justice, with which he had some practical experience. His experience and observations are generally printed in his memoir as he wrote them; but on some occasions, when his brother professes to render them in his own language, the biographer being a practising English barrister, makes a singular jumble of the Turkish administration by putting his allusions to it into the technical phraseology of the English law.

Very few dates are given in his biography, but it is stated that Dudley on his way home having touched at Smyrna, left that place on 25th March 1800. He wrote, as to his journey homeward, a 'Voyage from Smyrna, with an Account of Turkey, containing matters little known in Europe,' left unfinished. He spent his latter years in London. Soon after his return he was chosen sheriff, and knighted, and was afterwards elected alderman of Basinghall. He lived in London, the north end of the town with which as much as by his own merits, he was made a Commissioner of the Customs. Towards the end of the reign of Charles II. he was made a Commissioner of the Treasury, but on the accession of James II. he was banished, with the rest of the court. He spent his last days in France, where he himself somewhat unpopularity in his office by suggesting a tax on sugar and tobacco. In the mean time he had been chosen member of Parliament for Banbury, and took considerable interest in politics, with, apparently, a far more independent spirit than his brother, the lord keeper. His biographer oblige him the merit of having opposed resistance to the crown under the operation of closing.' He lost his office at the Revolution, and was suspected to be a pretty strong examination by both Houses of Parliament. He died on 31st December, 1691. (North's Lives of the Norths.)

NORTHUMBERLAND INLET, is a large bay on the eastern coast of North America, running nearly parallel to Davis's Strait and entering the continent to a distance of more than 150 miles from the open sea. Its entrance lies between 64° and 69° N. lat., and is more than 60 miles wide. Hence it extends in a northward direction, with a width increasing as much as by his own merits, he was made a Commissioner of the Customs. Towards the end of the reign of Charles II. he was made a Commissioner of the Treasury, but on the accession of James II. he was banished, with the rest of the court. He spent his last days in France, where he himself somewhat unpopularity in his office by suggesting a tax on sugar and tobacco. In the mean time he had been chosen member of Parliament for Banbury, and took considerable interest in politics, with, apparently, a far more independent spirit than his brother, the lord keeper. His biographer oblige him the merit of having opposed resistance to the crown under the operation of closing.' He lost his office at the Revolution, and was suspected to be a pretty strong examination by both Houses of Parliament. He died on 31st December, 1691. (North's Lives of the Norths.)

But
orders,
followed
thirty
fever,
that
however,
been
assigned
a
plan
for
the
purposes
of
classifying
peculiar
forms
of
fever,
but
the
causes
and
the
locally
were
employed;
thus,
mush,
jail,
and
other
fears
have
been
described.
In
this
way
the
materials
were
early
accumulated
for
a
system
of
nomenclature.
It
was
not,
however,
still
comparatively
modern
times,
that
anything
like
a
scientific
system
of
arrangement
was
proposed.
One
of
the
earliest
of
those
was
that
of
Sauvages,
who,
taking
the
most
prominent
symptoms
of
diseases
as
his
guide,
divided
them
into
ten
groups
which
he
named
Vita,
Febres,
Phlegmasia,
Spasm,
Anhelationes,
Debilitates,
Doloros,
Vesane,
Fluxus,
and
Cachexia.
Under
classes
were
arranged
various
orders;
thus,
the
first
class
arranged
the
orders,
Macule,
Ectoereticia,
Phymata,
Excectoereticia,
Cystides,
Ectopie,
Plagas.
The
order
Macule
was
divided
into
the
diseases
Leucosoma,
Vitiglo,
Ephelis,
Utines,
Nau,
and
Ecomyosoma.
This
classification
of
diseases
was
followed
by
those
of
Linnan,
Vogel,
Sager,
and
Macbide,
but
in
their
arrangements
they
all
recognized
the
same
principle
of
classification
as
Sauvages,
and
made
their
division
of
diseases
to
depend
on
the
greater
or
less
prominence
of
particular
symptoms.
All
these
systems,
were,
however,
supplanted
by
that
of
Cullen,
which
he
promulgated
in
the
second
edition
of
his
'Synopsis
Nasologiam
Medicae.'
The
following
plan
will
give
an
idea
of
its
structure:

**ECTOPIE.**

| 143 Vulnus | 144 Ulus |
| 145 Herpes | 146 Tinea |
| 147 Pueror | 148 Fractura |
| 149 Caries |
It was the simplicity of this system which recommended it in general adoption, and which has caused it to exercise a great influence over other systems of botany. At the same time it will be seen that this and the previous systems are purely artificial, and frequently bring together diseases of a very dissimilar character. Such systems can also led to the misconception of a character as definite as the objects of natural history, and that a species in the one can be as easily defined as the species of another. But it becomes evident, after a careful study, that the exception of those diseases that depend on peculiarity, no part of the idea of a species as applied to plants or animals can be made use of to designate particular diseases.

1. The fundamental principles of anatomy, physiology, and pathology, many attempts have been made to give a more natural arrangement of diseases than that of Cullen. Dr. Mason Good divided diseases into the following six classes:—

**Class I.**—Constitution: Diseases of the digestive functions.

**Class II.**—Pneumatics: Diseases of the respiratory function.

**Class III.**—Haematics: Diseases of the sanguineous function.

**Class IV.**—Neurotology: Diseases of the nervous function.

**Class V.**—Genitology: Diseases of the sexual function.

**Class VI.**—Eccritica: Diseases of the excretory function.

This system, however successful it may be regarded in its primary divisions, was too technical in its details to be very generally comprehended by the medical men of that age. The classifications founded on pathological distinctions is that of Pinel, who divides diseases into fevers, inflammations, humours, animal affections, and organic aetiologies. The great objection to this and the like is, that it is building upon the knowledge of the functions of the different parts of the human body, whilst the symptoms of diseases, being very evident, lead to the assumption of causes of disease and pathological states which probably do not exist.

Notidanus, a genus of fossil fishes from the chalk of Kent. (Agassiz.)

Notidanus, a genus of fossil fishes from the chalk of Kent. (Agassiz.)

WILLIAM, a lawyer, whose professional career had a considerable influence on British History, was born about the year 1577. 'He was,' says Fuller, 'for many years, the strongest champion of the subjects' liberty, until King James entertained him to be his attorney.' He was made Attorney-General on 21st October, 1631. He had for some years been member of Parliament, first for Helston, and subsequently for St. Ives. He was a profound lawyer and jurist, but he was overlooked by his contemporaries. It is probable the knowledge of the law was greater than all other men's by making that law which all other men believed not to be so. It was the characteristic of the great lawyer and jurist that he could not give a clearer testimony that his knowledge in the law was greater than all other men's than by making that law which all other men believed not to be so. It was to his reverence that one of his followers extended the name of superstipendiary to all those who followed his precepts and taught the same spirit, that the court owed the project of ship-money. Dower drew the writ for levying this illegal tax, but he did not live to see the momentous effects of his exertions, and died on 6th August, 1579. In 1577 he published a book on the Antiquities of the Church and the State, in which he endeavoured to show the origin of many of the most important institutions of the Church, and the fact that the Church was the creature of the State. This work was a great success, and was reprinted several times.

The expression subserve as before, prefixed to super, to denote the inverse ratio. The reader may fancy for himself, if he can, the beauty of a treatise in which the ratio of 4 to 11 is expressed by duplus subtripartitae. Not that the writers of these works were ignorant of more simple phrases; and we remember one place in which the example of Aristotle is brought forward to show that it would not be wrong to use them.

Of means, or mediocrities, Boethius discusses ten, to which Jordanus added an eleventh. The first three bear the names which have descended to us, arithmetic, geometric, and harmonic; and all are as follow. Let a, b, c be three numbers, of which a is the greatest and c the least.

1. \( a - b = c \)
2. \( a - b = c \)
3. \( a - b = c \)
4. \( a - b = c \)
5. \( a - b = c \)

The works of Boethius and his followers consist in dissertations on what would now be called the most obvious properties of the ratio of numbers, enriched with comments of every sort from nothing to the theological, and they should be utterly lost sight of, for they form a dark background on which the merits of Sacrobosco, Bradwardine,
NUMERALS, THEORY OF. We are here to supply an omission in the article on this subject, or rather in filling up the references which were made in it.

Euclid's geometry, assuming only the use of his three celebrated postulates, enables him, a linear unit being given, to construct the length represented by any algebraical expression which involves only additions, subtractions, multiplications, divisions, extraction of the square roots, or combinations of all these. But a cube or fifth root is beyond the power of the system.

Again, from the theory of equations it is soon made obvious that the solution of the equation \( x^2 = 1.0 \), and the division of a circle into \( n \) equal parts, are one and the same problem. One solution of the preceding is \( x = \cos \theta + \sqrt{1 - \sin^2 \theta} \), where \( \theta \) is the sub part of four right angles. [Boor, P.C.] Euclid, in his fourth book, shows how to cut a circle into three, four, five, and fifteen equal parts; and analysis shows that the sizes and cosines of the angles so involved can be obtained by formulæ which involve no roots except the square. But except into halves, thirds, fifths, or seventeenths, or parts obtainable from these by one or more bisections, Euclid was not able to cut a circle into equal parts.

So the matter rested for about 2000 years, until Gauss, in his Disquisitiones Arithmeticae (1801), not only pointed out how to extend Euclid's conclusions, but also in a manner how to account for them. The statement of his results, even without demonstration, is instructive to the learner, and we add (accordingly): referring to the solutions of antient equations, and the works of Gauss or Legendre [Numbers, Theory of, p. C.], or to Murphy's 'Theory of Equations.'

The expression \( a \pm \sqrt{b} \), or \( a \) being rational, is the solution of a quadratic equation with rational coefficients. But if \( a \) and \( b \) themselves have the form \( c \pm \sqrt{d} \), in which \( c \) and \( d \) have themselves the same form, and so on; then \( a \pm \sqrt{b} \) is the solution of the equation \( x^2 = 1.0 \), and the division of a circle into \( n \) equal parts, or the \( n \)-th root of \( \sqrt{d} \), and so on. Consequently, any equation, the root of which is capable of construction by Euclid's postulates, must be reducible to a system of quadratic equations, and so on.

Now if \( n \) be a prime number, \( n - 1 \) is an even number, and therefore has factors. Let its prime factors be \( b, b, c, \&c. \), and let them separately enter \( p, q, r, s, \&c. \) times: so that

\[ n - 1 = 2^a \cdot b^2 \cdot c \cdots \]

Gauss succeeded in showing that if \( n \) is a prime number, the solution of the equation \( x^n - 1 = 0 \), can be made to depend upon the solution of \( p \) equations of the second degree, \( g \) of the fourth degree, \( r \) of the sixth degree, and so on. Consequently, whenever \( 2 \) is the only prime factor of \( n - 1 \), or when \( n - 1 = 2^a \), and \( n \) is prime, or when \( n - 1 = 1 \) is a prime number, the solution of the quadratic equations, and the division of the circle into \( n \) equal parts can be accomplished by Euclid's geometry. And further, it easily demonstrated that \( 2^a - 1 \) can never be a prime number, except when \( p \) itself is a power of \( 2 \) \((2^\text{m})\) included, though \( 2^a - 1 \) is not then always prime. Nor has it been shown that other divisions are impossible: Gauss's theorem merely points out cases in which the thing can be done, without pronouncing the exclusion of others. Gauss, indeed, does assert that he can demonstrate all other cases to be impossible to be constructed by geometry, that is, reducible to quadratic equations: and if we now consider the three \( 2^a + 1, 2^a - 1, \&c. \), among which all our chances lie, we have \( 5, 17, 257, 65537, 4294967297, \&c. \) The first five are prime numbers; Euclid has disposed of the first two divisions; Gauss has added that a circle can be geometrically divided into 17, 257, and 65537 equal parts. But 4294967297 is not a prime number, being divisible by 641. Euclid's mode of obtaining the division into 18 parts can also be extended.

From this and the preceding, the problem of Euclid, and those of \( \sqrt[3]{3}, \sqrt[5]{2} \), and \( \sqrt{7} \), are solved.

The problem of the quadrature of the circle is not susceptible of such an analytical solution as the problem of finding the root of a quadratic equation. But it is not impossible, by the method of the 'Greece Mathematisches' (1690, vol. i. p. 38) of Deechies, who gives it as the opinion of several of his time. And the earliest hints (by no means complete, and mixed with some absurdities) which we have found are in the 'De Numeris Libri Duo' of John Novomagus, Acts, 30, 8vo.

OBSIDUENS, JULIUS, the author of a small work in Latin, which appeared in 1779, and was entitled De Præsulis. Nothing is known about the author. Scaliger concludes that Obsidues lived before Hieronymus, because Hieronymus in a particular passage appears to have copied a fact from Obsidues. This passage of Hieronymus was written in the year of 379 A.D. The work of Obsidues is a record of wonderful things that happened during the period from the foundation of Rome to the time of Augustus. The first part of the work is lost, but it has been supplied by Lycosthenes, whose supplement commences with the time of Romulus and extends to the year of 668, when the extant work of Obsidues begins. There are various gaps also in 503, which Lycosthenes has also supplied. The method of the author is to enumerate the wonderful occurrences under any given year, and then state what happened thereon. The following is an example (No. X. 1.):—It rained milk on Mount Grecoastasia. At Croton a calf of sheep with a dog and three shepherds were killed by lightning. At Satura a calf with two heads was born. There was an uproar in the city owing to Gracchus proposing his laws. Obsequens chiefly followed Livy, for he uses pretty nearly Livy's words, as appears from a comparison of Obsidues with those parts of Livy which are extant. His work also terminates with an event relating to Drusus, the son of Tiberius, and he daily of Livy terminates with the death of Drusus.

Lycosthenes in his preface argues that the attention which the Romans paid to wonderful occurrences and signs proved their religious feeling, while their blindness is shown by their worship of false deities; and he adds that if they had been acquainted with the true religion, they would have surpassed in religious zeal and posterity, who are Christians rather in name than in fact. The divine signs of the times foretold by Jesus Christ (Luke xxi.), as to happen when the end of the world was approaching. Among the signs then recently witnessed the author mentions three or four eclipses happening in a year, stars with hair (cometa), burning meteors, and earthquakes and convulsions of the earth in Italy, all which made no impression on the people of that day, to such a height of impiety and wickedness were men come. The consequences of all this were pernicious errors, horrible blindness, and persevering blasphemy; and the divine vengeance showed itself in civil wars, strange diseases, and famine. The author thought that an edition of Obsequens would be a work of much advantage; and he published a portrait which he had exhibited at the French Academy of Painting, for a picture of the death of Phocion, and had the honour of being presented to the emperor. He returned in the same year to Bruges, and in 1805 he went as a pensioner for five years of the French government to Rome, but he remained there about eight years. He finally wrote the regulation of the French government, be sent, after his residence of five years in Rome, an historical picture to the French Academy; the subject was the Coronation of Charlemagne, and it was exhibited in Rome to paint two large frescoes for the palace of Monte Cavallo, but political events which followed prevented the execution of these works. He left Rome at the close of 1812, and returned to Paris, and obtained the gold medal for a picture in the exhibition there. He returned finally to Bruges, where he executed several public and private commissions. In 1816 he established himself in Brussels, where he painted his pictures of the Peace of Utrecht, and the Battle of Waterloo at the moment the Prince of Orange was wounded, for the King of the Netherlands, who had created Obsequens his court painter in the spring of 1816. The Battle of Waterloo was exhibited in 1817 and 1818 in many of the provinces of the Netherlands, together with a portrait of the Prince of Orange, which is engraved by Galigni, and a picture of Brunante introducing Raphael to Julius II. Obsequens was the commissioner appointed on the part of the Netherlands to reclaim the pictures which had been taken by the French to Paris from the collections of Holland and Belgium. Upon the completion of this commission, the King created him a Chevalier of the Lion of the Netherlands, and several Flemish cities presented him with medals struck expressly in commemoration of the restoration of their respective works.

The Battle of Waterloo was followed, in 1820, by the Battle of Nieuwpoort, and a Nascaen, engraved by Vlamynck. In 1821 he exhibited at Brussels his Triumph of Cimabue: and subsequently David in his studio; the Establishment of the Power of the House of Orange; the Inauguration of the King at Brussels in 1815; besides others from classical history, and many scripture-pieces for various churches in the Netherlands, in some of which are excellent altarpieces by Obsequens. He died at Brussels, in February, 1830, not having completed his fifty-second year. Van Eynden and Vander Willigen, in the third volume of their 'National History of Painting since the Middle of the Eighteenth Century,' published in 1830, have given December 2, 1776, as the date of Obsequens's birth, which is corrected in the fourth volume of appendix, published in 1840, to the date given above. His works have been exhibited in the Royal Academy of Brussels, and in the International Exhibition of Antwerp in 1835, and at the Brussels Exhibition of 1848. His portrait is by Gracchus. The works of Eckhout and Burggraaf, Portraits of the Artistes modernes, etc., Brussels, 1822, and several of his works are engraved in the 'Annales du Salon de Gand'—as the Coronation of Charlemagne; the Confusion of Languages; and the Battle of Nieuwpoort. Some of the pictures of Obsequens are of very large dimensions. He was a member of the Academy of St. Luke at Rome, and of several other institutes of the fine arts. (B. Van Eynden en A. Van Der Willigen, Geschiedenis der Nederlandse Schilderkunst, sedert de left van de xvii. Eeuw, Amsterdam, 1842.)

O'DOMETER (from odo, a road, and µέτρον, a measure) is an instrument used for measuring the distances passed over in travelling, and is very nearly the same as that which is called a Pedometer; the latter is carried in the pocket of a person on foot or on horseback, and the former is attached to a carriage. (Pedometre, in 5th Ed. of Geograph.)

OECCUMENICAL COUNCILS. [Concil of the ChurcH, P. C. S.]

OEDEMERA, a genus of beetles belonging to the third family of heteromeres, head and thorax. (Linn.)

GENOTHERA, a genus of plants belonging to the natural order Onagraceae or Onagraceae. It has 4-eleft calyx, 4 petals, a filiform style, with a clavate or cruciform stigma, linear capsules with 4 valvées, and a tuft of hairs. (Gen. binnisii, Evening Primrose, bas ovato lanceolato flattoothed leaves, a rough hairy stem, petals longer than the stamens and about half as long as the tube of the calyx. The flowers are large, and a tuft of hairs is seen on the base of the flower. It abounds on the Lancashire coast, and covers several acres of ground near Woodbridge, Suffolk. The roots are establie, 311, 2.
and were formerly taken after dinner to flavour wine as olives now are; therefore the generic name was changed from Ougas, the ass-food, to Gugione, the ass's oil. This plant was "noted in the cultivated part of the <as-conf.> for its oil, which in some measure has stood instead of the potato had they not been superseded by the introduction of the latter. This is the only British species of the genus. There are 85 species, monoecious, found in Europe. Oggione is a branch of the same family. They are handsome border flowers, and deserve to be cultivated, but are not valuable on account of any properties they possess. They will grow in any common perennial soil, and may be increased by seed, by dividing the plants at the root, and some of them. The seeds of the annual and biennial kinds only require to be sown where the plants are intended to remain.

(D'Orchard's Dictionary; Babington, Manual of British Botany; Burnett, Outlines of Botany.)

OFFERINGS, OBLATIONS, AND OBLIGATIONS are not only those small customary sums paid at Easter, but also the customary payments for marriages, churchings, christenings, and burials. By 2 & 3 Ed. VI. c. 13, 'all persons which by the laws and customs ought to make or pay their offerings, shall yearly well and truly content and pay the same to the parson, vicar, proprier, or their deputies or farmers, of the parishes where they shall dwell or abide;' and that at such four offering-days as at any time hereafter within the space of four years hereafter shall be used and accustomed for the payment of the same; and, in default thereof, to pay for the said offerings at Easter next following. The four offering-days above spoken of were Christmas, Easter, Whitsun-tide, and the festival of the dedication of the church. It is directed by the rubric, at the end of the Communion Service, that 'in the morning every one that at this offering shall be excused to commune at the Table of Christ, and to the parson, vicar, proprier, and their deputies or farmers of the parishes where they shall dwell or abide; and that at such four offering-days as at any time hereafter within the space of four years hereafter shall be used and accustomed for the payment of the same; and, in default thereof, to pay for the said offerings at Easter next following.' The four offering-days above spoken of were Christmas, Easter, Whitsun-tide, and the festival of the dedication of the church. It is directed by the rubric, at the end of the Communion Service, that 'in the morning every one that at this offering shall be excused to commune at the Table of Christ, and to the parson, vicar, proprier, and their deputies or farmers of the parishes where they shall dwell or abide; and that at such four offering-days as at any time hereafter within the space of four years hereafter shall be used and accustomed for the payment of the same; and, in default thereof, to pay for the said offerings at Easter next following.'

Surplus-fees are payable for every marriage, whether by banns or by licence; and for every funeral, churching, or christening, according to the custom of the parish. Mortuaries are claimed on the death of each person in a parish, according to the value of property left, but not to a greater amount than 1s.

(Bill's Sociologia.)

OGGIONE or OGGIONE, MARCO DA, a Milanese painter and distinguished scholar of Leonardo da Vinci at Milan about 1490; he was born therefore about 1470, at Oggione, in his native district. He painted in oil and in fresco, and is on the whole one of the best of the Milanese painters. His frescoes of the church della Pace at Milan, which are much praised by Lanzi, are now in the possession of Baron Baber of Milan; they were removed from the church by Barabazi. Oggione is however now chiefly known for his copy of the 'Last Supper' of Leonardo da Vinci, now in the Academy of Arts in London. This copy is paints by oil for the Refectory of the Certosa di Pavia; and as it was copied when the original was in a perfect state, the now almost total decay of the latter renders it very valuable. The opinions regarding its merits are various. Giuseppe Bezzuoli kindly approved of it; but as the original has been virtually decayed since 1726, when it was first restored, all subsequent judgments of the merit of the copy with respect to the original must be received with due reservation, as they are not the result of individual fancies of what the original contains. The remains of the original are on the other hand the basis of all critical speculations of the critics combined; they have no right to assume a deviation from the original, when they cannot possibly demonstrate it. Oggione made two large copies, both, it is said, from a small copy made by himself. One is in the Royal Academy, and one in fresco for the Refectory of the convent of Castelazzo, which was copied by the Cav. Giuseppe Bosi, though not finished. Bosi's picture was taken chiefly from a copy in the Ambrosian Library made by Andrea Fontoni called Vulpio in 1819, when the original was already much decayed. There is another copy by Francesco Capriani, made in 1565, and attributed to Pietro Luini. Bosi's copy was made in 1807 for Eugene Beauharnais, viceroy of Italy, to be worked in mosaic; the cartoon is now at Munich, and the mosaic was executed partly from another, from studying other works of Da Vinci, and from the artist's own feeling of Da Vinci's style, is essentially a restoration or translation, and not a copy it may have no resemblance to the original in the size and composition; and to the true lover of art can have little value, compared with the old unassuming copy of Oggione. The mere fact that Oggione's copy was painted for people who had not seen the original, and by a distinguished pupil of Leonardo's from the original when in its perfect state, ought to be sufficient guarantee for its fidelity, notwithstanding its imperfections, making of course due allowance for the different capacities of the two men. Marco da Oggione died in 1590.

(Lanzi, Storia Pittorica, &c.; Götze, Propylaen.)

OHMACHT, LANDELIN, an eminent German sculptor, was born at Donningen near Rottweil in Württemberg, in 1760. He was the pupil of J. P. Moltchier. His first public works were some sculptures for the Kreuzkirche at Rottweil, which still decorate the choir. He executed the following other works in Strassburg: In 1790 he went to Rome, where he remained two years, and after his return to Germany he was employed on several important monumental works, the first of which was the monumental statue of the cathedral of Lübeck; but his principal works are at Strassburg, where he settled in 1801. His first work there was the monument of General Desaix, who was killed at Marengo, erected on the spot near Strassburg where there are four monuments also by him in the church of St. Thomas, of which that to Professor Oberlin (1810) is one of his principal works; that to the historian Koch (1815) is likewise much admired. He executed also a monument in the church of Dr. Blessing; another to General Kleber, in the cathedral; and a colossal figure to Adolph von Nassau, in the cathedral of Speyer. There are several classical figures by Ohmacht—such as Apollo, Minerva, Mars, &c., in the Judgment of Paris (at Nymphenburg), and others. Among his busts are several of Klopstock, with whom he was intimate. He died at Strassburg, in 1834: his portrait is in the Vogel collection of portraits in the possession of the king of Saxony. The celebrated sculptor David, upon seeing the works of Ohmacht at Strassburg, is reported to have said that one could not sufficiently admire them, and that Ohmacht was the Correggio of sculptors.

(Nat. Alleman. Kunstler-Lexicon.)

OIL-PAINTING. (Etex, John Van, P. C., p. 138; Painting, P. C., p. 142.)

OILS, BRUSHWOODS OF. (Painting, House, P. C., p. 145; Staining, P. C., p. 479.)

OILS, MANUFACTURE OF. An account of the properties of the more important oils, and of the materials from which they are employed, is given in P. C., pp. 410, 411. Oils, Vegetables, P. C., p. 417; and further information may be found under the names of some of the principal oils, as Croton Oil, Linseed Oil, and Oylve Oil, or in articles which treat on the materials from which oils are made, such as Elmi, Madia, Linseed, Oyle Europ., Ricinus Communis, and Guajacho Blu. Under Fisheries, also (P. C., pp. 288, 289), is given much information on the produce of whale oil. We may here add a few words on the processes of the manufacture of such oils as are of the greatest commercial importance.

The manufacture of animal oils requires very little notice beyond what is given in the articles Oyle and Fisheries above referred to. The blubber, or fat from which the oil is procured, is usually cut into small pieces and packed in casks soon after it is taken from the whale; it is then brought home in a half-putrifying condition, and is emptied into some vessel or receiver capable of holding several tons. From this receiver the decomposing fat is conducted, after settling for a few hours, into a copper boiler, in which the separation of the fluid from the matter of the blubber is completed by the action of heat. From the boiler the oil flows through a kind of filter of brushwood, which detains the grosser impurities, into coolers, from which, when quite cold, it may be drawn into large barrels. Various processes are employed for purifying whale oil and diminishing its unpleasant smell. The quantity of oil obtained is about four-fifths that
OIL

OIL

The blubber used in the South-Sea fishery is it found advisable to separate the solid residue, by boiling in hermetically sealed vessels, and so bring home the oil alone in casks. In this process, as commonly performed, the oil is very imperfectly extracted from the blubber, and the scum, or solid portions which remain, are pressed between two rollers; but which arrangement the oil that remains in them is not only destroyed, but also becomes, from its great inflammability, a source of serious danger. To obviate these evils some ships are provided with powerful screw-presses for squeezing out whatever oil may remain after the process of boiling the blubber, and thus materially increasing the produce. Herbold, in 'the Engineer's and Mechanic's Encyclopedia,' vol. ii. pp. 172, describes an apparatus of this kind, in which the blubber-scrapes are put into a hollow cylinder, while yet warm, and compressed by a piston brought down upon them with a great force. The oil escapes through holes in the bottom of the cylinder, between which the blubber is laid a mattress of wicker-work, to prevent the blubber from chocking up the holes. This press is the invention of Mr. John Blythe, of Limehouse.

Olives, as explained under Olea Europaea, in P. C., differ from most vegetable expressed oils in being extracted from the soft fleshy pericarp, whereas such oils are usually procured from the seeds only. The manufacture is very simple, and requires no machinery; but writers differ in their accounts of the process, in some important particulars; some stating that the fruit should be gathered a little before it is ripe, and spread on the floor of a roofed court, or in a room; while others place the volume on 'Vegetable Substances used as Materials of Manufacture,' in the 'Library of Discoveries in Knowledge,' it is stated upon the authority of an English gentleman who had resided at Gallipoli, where much excellent olive oil is made, that the Gallipolitans never gather the olives, but allow them to drop in their maturity from the tree to the ground. In the 'Dictionnaire de l'Industrie,' published at Paris in 1795 (vol. i. p. 78), in an account of the manufacture of olive oil in Provence, however, it is stated that fallen olives should not be mixed with those which are gathered, for fear of imparting an earthly odour to the oil, and a caution is given against allowing the heap of gathered olives to heat or ferment, coupled with the remark that the sooner the olives are taken to the mill the better will be the oil. According to this authority, also, all leaves should be carefully removed, as their presence would give a bitter taste to the oil. But Dr. Ure, in the 'Dictionary of Arts,' &c., p. 898, writing of the same district, states that it is usual in the neighbourhood of Aix, in Provence, to preserve the olives for fifteen days in barns or cellars, with ample ventilation, in order to facilitate the extraction of their oil. 'If,' he adds, 'this practice were really prejudicial to the produce, as some theorists have said, would not the high reputation and price of olive oil in the market be due to the habit of the French in inducing them to change their system of working?' In fact, he proceeds, 'all depends on the degree of fermentation excited: they must not be allowed to mould in damp places, to lie in heaps, or to be charged with reddish liquor, or to become so hot as to raise a thermometer plunged into the mass up to 86° F. . . . A slight fermentation, however, is useful towards separating the oil from the mucilage. The first and finest oil is obtained by crushing the olives in a kind of mill, termed by Dr. Ure an edge-mill, in which the crushing-stones are so mounted as not to break the stones of the fruit, but simply to crush the pulp. The mass thus bruised is put into coals, or bags made of haircloth, or of coarse canvas, which are piled or laid upon one another to the number of eighteen, and exposed to gradual compression in a screw-press; and the oil which flows from the coals, which is the pure virgin oil, is conducted by channels into casks or stone cisterns partly filled with water, on the surface of which it floats so that it may be readily collected by skimming. When the oil ceases to flow, the mass of pulp is taken out of the bags, mixed with boiling water, and treated as before, but with an increase of pressure. The second quality of oil thus procured is quite fit for table use when fresh, but is apt to become rancid by keeping. After skimming, when cold, the subjacent water still retains a good deal of oil, by the intervention of the mucilage; but after long repose in a large cistern the oil and water separate, and the water may be drawn off. Owing to the nature of the process, the oil is very liable to deteriorate in quality, and can only be used for factory purposes. A still coarser kind of oil is finally procured by crushing the marc, or solid residue, which is pressed out of the stone vessels and brought home in the same manner, and then mixed with water, and re-pressing it. All the oil, Dr. Ure observes, must be fixed by keeping in clean tuns, in an apartment heated to at least 60° F., for twenty days, after which it is run off into strong casks, cooled in a collar, and then sent into the market.

Dr. Ure, in the article and page above referred to, gives the following useful directions for refining olive-oil for the use of watch-makers:—'Into a bottle or phial containing the oil, a slip of sheet-lead is immersed, and the bottle is placed at a window, where it may receive the rays of the sun. The oil by degrees gets covered with a curdy mass, which, by being pressed from the bottom of the phial, gives it a limp and colourless. As soon as the lead ceases to separate any more of that white substance, the oil is decanted into another phial for use.

Passing over the processes of manufacture of many kinds of oil of less importance, we proceed to take linseed-oil, or the oil extracted from the seeds of the flax-plant, as an illustration of the manufacture of oil from seeds. 'Linseed, rape-seed, poppy-seeds, and other oleiferous seeds were,' Dr. Ure observes, 'formerly treated for the extraction of their oil, by pounding in hard wooden mortars with pestles shod with iron, set in motion by cams driven by a shaft turned with horse or water-power; and the pressed-out oil was collected in bags, which were wrapped up in hair-cloths, and squeezed between upright wedges in press-boxes, by the impulsion of vertical rams driven also by a cam mechanism. In the best and most approved of these flax-mills, near Newcastle-upon-Tyne, is given in Dodd's 'British Manufactures; Chemical,' (forming No. xiv. of 'Knight's Weekly Volume,' and in No. 802 of the 'Penny Magazine,' where also are some interesting details respecting the mode of cultivating and preparing hemp-seed and rape-seed for oil-manufacture. When flax is cultivated for its seed, the plants, after being pulled up, are either laid on the ground in handfuls, with the seed end towards the south, or else several plants are tied together at the top, and placed upright with their roots spread out. When they have been thus dried by exposure to the air, the seeds are separated from them by means of large ripes, or coarse teeth. When the flax is grown as an industrial plant, the seeds are removed, and by which the capsules containing the seed are separated from the flax. [Flax, P. C., pp. 303, 304.] The seeds and pods are then spread thinly upon a platform, and the wind by means of a current of air causes these pods of themselves, while such as are less ripe will need to be lightly trodden or thrashed. The whole is then carefully sifted, winnowed, and cleaned from dirt and chaff.

As the hard seed of this plant, or rough flax-seed, has a tendency to slide away unbroken under the ruffling action of the millstones by which they are ground, it is well, before taking it to the grinding-mill, to bruise or crush it by causing it to fall from a hopper between two iron crushing-rollers, placed side by side, and capable of being pressed against each other with any determinate degree of force; but the use of such rollers is by no means universal, the seeds being, in many cases, submitted to the grinding-mill without any such preparation. This mill, which is sometimes called an edge-mill, consists of a pair of stones, technically called running-stones, or rollers, usually made of granite, resembling grindstones in shape, and from five to seven feet in diameter, so mounted as to roll round in a circular path of small diameter upon a solid horizontal bed of stone or iron laid beneath them. These stones, which roll the bed from thirty to thirty-six times in a minute, are sometimes hooped with iron, though many prefer the rough surface of the granite, which may be re-dressed with a hammer as often as is needful. They grind the seed partly by their weight, which often amounts to three quarters of a ton each, and partly by their motion, the friction arising from the circumstance that the outer edge of the stone has to perform a larger circular path than the inner, although the two must of course revolve round the axle at one and the same speed. The seeds are thus very intimately ground, so that the grit is forced to roll onward in a straight path. The two running—
stoned are mounted on the same horizontal axis, but at rather different distances from the central vertical shaft or axle round which they roll, so that they do not follow one another in precisely the same path on the bed of this mill. The bed is surrounded by a rim which prevents the seeds from being scattered. In some instances a frame is fixed with the running stones, which are mounted carriers also in two racks or sweeps, which collect and lay the seeds in a ridge along the circular path of the runners. By this means the seeds are reduced, by the partial expression of the oil, to a pulp, from which a limited quantity of very fine cold-pressed oil may be obtained by the simple action of the press.

Owing to the extreme hardness and smoothness of the seeds, and to the circumstance that the fragments of their shells, however broken, form minute concavities which will retain the oil unless a greater pressure be applied than could be given by an ordinary screw-press, the press employed for extracting oil from such seeds differ materially from those used in crushing olives and other comparatively soft oleaginous substances. Hence it is that the wedge-press and Bramah's hydraulic press have been introduced for the purpose, and that of these two powerful machines some manufacturers prefer the former, believing that the same degree of pressure is more efficient when imparted by means of sudden impulses or blows upon the end of a wedge, than by the gradually and gradually increasing pressure of the hydraulic press. In the wedge-press, of which there are many varieties, the crushed seeds are put into bags of hair-cloth or some similar material, and these bags are then placed between the arms of a wedge, so arranged that they are pressed by means of wads or blocks of wood, within a very strong and massive framework. The small end of a wedge is then introduced in such a way between the plates or boards that, when it is driven down by the blows of a ram or pestle, it may compress the bags with enormous force. Barlow, in his 'Treatise on Manufactures and Machinery,' in the 'Encyclopaedia Metropolitana,' in which work (sections 504—615) is an important information on the subject, states that the driving of the wedges is continued until they are so tight that the pestle rebounds from them three times, when they are judged to be sufficiently driven. The use of the hydraulic press instead of this apparatus needs no minute explanation. In Barlow's work, just referred to, is an account of such a press which acts horizontally, the bags being, as in the wedge-press, placed vertically, and separated from one another by cast-iron plates; but in Dodd's account, above noticed, of the Walker oil-mill, the bags are represented as piled upon one another in cast-iron cases, and placed in a vertical press. Dodd speaks of the bags in which the seeds are put as woolen, 'unfolded (unfolded?) by horse-hair mattresses, enclosed in leather wrappers.' The last-mentioned writer states that the first oil-mill in which the hydraulic press was thus employed was built at Bremen, in 1851, and that its proprietor was satisfied with the superiority of the plan to any other then in use. Among other advantages it is stated that the hydraulic or hydrostatic press requires less space, and that in some cases, besides the oil and cake, no other by-products are obtained. The cake, and the hairs and bags are found to last longer with it than with the old machine. Since the above date the Bramah press has been successfully applied in the manufacture of cocoa-nut oil, and several presses have been exported to Ceylon and other places for that purpose. Mr. John Hall, of Dartford, patented in 1833 an ingenious oil-press in which the power of a steam-engine or other prime mover was to be applied through the medium of cause or fanlematic rollers: but Barlow states that the plan has not been generally adopted.

We have hitherto spoken only of the extraction of the fat matter by means of heat before the cold pressing is bowever necessary for obtaining the principal supply of oil. The precise order of the several operations, as well as the nature of the machinery employed, differs in different manufactures. The different processes for the extraction of the oil-cake, or solid contents of the bags, which remain after the first cold pressing, are taken out of the bags, broken to pieces, and put into mortars to be pounded by pestles with cold water. 'Fingers, hands, and the pestles and the paste again broken down, and the parenchyma of the seed reduced to a fine meal; thus free egress is allowed to the oil from every vesicle in which it is contained, but it is now rendered more efficient by the addition of a few drops of rottenstone and even of the fine parts of the meal. When sufficiently heated it is removed to a chaffeur, or circular copper-pan, in which, while it is kept continually stirred by machinery, it is heated to about the temperature of melting bees-wax, either by a charcoal fire, or, according to a more recent practice, by steam. It is then, while hot, put into the bags and subjected to a second pressing; and in some cases the like operations are repeated a third time. The last oil-cake, which is of inferior quality, is produced. Sometimes the produce of oil is increased by mixing a little water with the paste; but this practice is considered to impair the quality of the oil. The oil-cake is also often used as food for cattle, and for various other agricultural purposes; but of course they vary greatly in richness according to the degree in which they have been divested of oil. Barlow states, indeed, that they have no other employment than extracting oil from the cakes which they purchase from the French and Brabanters, after passing the process of their mills; a clear indication of the superiority of the Dutch practice. In some of the Dutch mills, we learn on the same authority, the produce is increased by the application of moderate heat during the grinding process, by enclosing a little furnace in the bed upon which the running-stones roll; but it is observed that "the utmost care is necessary to prevent the heat from becoming too considerable, as it causes the oil to dissolve too much of the fermentable substance of the seed, and exposes it to the risk of fermentation." Moreover, the bran or布朗 which is thrown off as a by-product of the process of grinding may be facilitated by the addition of a little water. The oil produced by the above process need not further attention. If left in a cistern, as it is by the Dutch manufacturers, the oil, which is at first relatively passes away with the oil in some degree in the operation of pressing, will gradually subside, and the oil may be drawn off at various levels, of different degrees of purity; the bottom being at length removed to a deep and narrow container where it should be left a considerable time for the dregs to subside.

Linseed oil is used principally as a vehicle for mixing oil-colours for painting, but it is also valuable in several branches of manufacturing industry, and, in a refined or purified state, in some medicinal preparations. Being a fat or succulent oil, it is slow in drying, and as this is a great inconvenience for some purposes in painting; it is sometimes converted into drying oil by boiling it with sugar of lead, white vitriol, red lead, or other substances which possess similar properties. The common kinds of drying oil are generally known by the name of boiled oil.

Very full details of the improved modern machinery used in the manufacture of oil from seeds are given by Barlow, in the work above quoted, in Dr. Urey's Dictionary of Arts, and in Supplement to that work; and some ingenious processes of simpler character are described in Hébert's "Engineer's and Mechanic's Encyclopaedia;" and in both of these works additional details may be found of the machines for second pressings, and other generally important character. The process of making castor oil is detailed under Ricinus communis, P. C., p. 5, 6.

O'KEEFFE, JOHN, was born at Dublin, on the 24th of June, 1747, the eldest son of Mr. Hugh O'Keefe, a stonemason, who died when only six years old, under the charge of Mr. West at the Royal Irish Academv; and his literary education, in Greek, Latin, and French, was received from Father Austin, a learned Jesuit, and his family being Roman Catholics. Two years of his youth, beginning when he was about fifteen, were spent in London with an uncle. From early boyhood he had dabbled in versification; at the age of sixteen he had composed a comedy, and when he was no more than eighteen another comedy of his was brought out by Bossow, at the Smock-alley Theatre in Dublin. His dramatic turn now took entire possession of him. He obtained for engagement in the Smock-alley Theatre, one of the chief companies, a footman's place, and on other parts which he held for some years to be a member of the company; acting both in Dublin and in other towns of Ireland. At the same time he exercised himself in dramatic writing, often producing small comedies, farces, and ballads. In the year 1764 he married a daughter of Mr. Heaney, proprietor of the Theatre Royal in Dublin, by whom he had three children. Domestic disagreements arose: after seven years of union Mr. O'Keefe deserted his wife, and the marriage was annulled; and the separation lasted for the remainder of their lives.

In 1778 Mr. Colman brought out successfully, at the Hay-market, the farce of 'Tony Lumpkin in Town,' the first Irish drama that was properly acted. In the year 1781, on his separation from his wife, he removed to London; and he never again visited his native country. From that
time he was a play-writer by profession. The greater number of his pieces were composed for Colombia at the Haymarket and, Weimar and under the management of Harris. His dramatic career may be said to have closed in 1788, after which date no new play of his was brought upon the stage. The fruit of his labours was the local length of the annuity, his own list, to no fewer than sixty-eight, of which fifty-six were acted, and many of these with great success. Some of them still keep possession of the stage. Such are his comedy of Wild Oak, and his operatic facies of The Agreeable Surprises and The Highland Reel.

O'Keeffe's works do not belong to a high class. Their diction is coarse, and in incident and character they are merely farcical. Nor did O'Keeffe but the planet, few but the bat, ought 1801, for three but those 1830, to the 1798, and, added 1768, to the 1799, to the 1802, and, added 1779, 1781 and 1776; those of two comets which appeared in each of the years 1798 and 1799, of one in 1802 and of the great comet of 1811.

The interval between the orbits of Mars and Jupiter, which appears disproportionately great when compared with the intervals between any two of the other planets belonging to our system, had suggested to the original and inquisitive mind of Kepler the idea that the planet, too small to be seen from the earth, existed in that region: the idea appears to have been little regarded till M. Bode, of Berlin, obtained his empirical formula, for the distances of the planets from the last, that region, and of Jupiter, found to hold good for all the known planets, including the Georgian; when that which was before considered as the vision of an enthusiast was found to be deserving of serious consideration. With a view, therefore, of securing, as far as possible, a complete examination of the heavens in the parts where the supposed planet might be expected to be found, M. Schröter was induced to form an association of twenty-four astronomers, who, having divided the heavens into as many zones, were each to confine his observations to one of them. That distinguished individual was chosen President, the Baron Zach secretary; and among the members was Dr. Olbers: the latter, who conceived the association immediately rewarded; and M. Piazzi, of Palermo, who was not one of the number, had the good fortune to discover January 1, 1801, a planet, to which he gave the name of Ceres, and which was afterwards, by Dr. Olbers and Jupiter, at a distance from the sun nearly equal to that which, in conformity to the law discovered by Bode, it ought to have.

This planet soon afterwards became invisible, from its vicinity to the sun; but Dr. Olbers and M. Gauss, having calculated its orbit approximately from such observations as had been obtained, sought for it at the time when it was expected again to appear, and the former was the first to re-discover it. The idea of Kepler and the formula of Bode seemed now to be fully confirmed; but the harmony conceived to exist in the planetary distances was almost immediately, in appearance, deranged; for on the 28th of March, 1802, Dr. Olbers, being engaged in examining the northern part of the constellation Virgo, discovered a star which was not in any of the catalogues of stars. The accidental discovery, however, was the same as that of the last-mentioned planet, but it has a much greater inclination to the plane of the ecliptic. Dr. Olbers was led, from the fact that these two planets are nearly in the same position in the sky, and from the same part of the ecliptic, to have a third planet at a distance from the earth which is almost equal to that of the planet discovered by Bode, whither the conjunctions of the planes of the orbits intersect one another, to imagine that they might be dispersed fragments of a large planet which revolved, at one time, about the sun at nearly the same distance that it has been broken up. Par-
He noticed the comet like he had noticed Juno, has the nodes of its orbit near those of Pallas. Ogilvie and Bessel computed the eccentricities of the two planets are nearly equal to one another, and both planets revolve about the sun at nearly the same distance. Dr. Olbers now determined to make the discovery of new planets a particular object of research; and, from 1804 to 1807, he persevered in examining with the most minute attention, at the times of their opposition to the sun, the parts of the heavens which were near the nodes of the other planets. On the 3rd of April, in 1807, his sagacity and diligence were rewarded by the discovery of a fourth planet: on the 2nd of August he made intelligence of the event to his friend M. Bode, and he transmitted the series of his observations to M. Gauss. The latter astronomer immediately computed the figure of the orbit, and, Olbers having requested him to give a name to the planet, he designated it Vesta. This is the smallest of the new planets, or asteroids, as they have been designated, and the time of its revolution about the sun is the shortest.

It may be proper to mention, in this place, that additional confirmations of the opinion of Olbers have been afforded by the discovery of a planet Vesta, in the month of October, 1845, by M. Hencke of Drisen, and it has received the name of Astraea; it is a small planet, and revolves about the sun, between the orbits of Juno and Vesta, in about four years.

In 1815 (March 6th) Dr. Olbers discovered, near the constellation Pegasus, a comet which presented the appearance of an attenuated nebulous without any visible nucleus; and he continued to observe it till the end of August, when it ceased to be visible; its orbit was calculated by Bessel and Gauss, and it was found to accomplish its revolution about the sun in 73 years. In 1826, he published a dissertation on the probability that a comet may come in collision with the Earth—a subject which then engrossed the attention of astronomers on account of the near approach of the comet Biela when one part of its orbit. In 1841 he made a proposal for a re-formation of the constellations and a revision of the nomenclature of the stars; recommending, as models, the figures in Flamsteed's Atlas, but better drawn than they are in that work, and also that the representations of persons and machines which have no relation to astronomy should be cancelled.

Dr. Olbers was elected a fellow of the Royal Society of London in 1804, and a Foreign Associate of the Académie des Sciences at Paris in 1822; he was also a corresponding member of several other learned societies, a knight of the order of Dannebrog and of the Red-Eagle of Prussia. He died at Bremen on the 2nd of March, 1840; and, as a proof of the esteem in which he was held, the inhabitants of Bremen placed his bust in the public library of the city.

OLDIXON, JOHN, one of the heroes of the Duscid, was born in 1678. The place and kind of his education are unknown. His authorship appears to have begun with the drama, in which he was thoroughly unacquainted: and his principal productions were historical, political, and critical. He superintended, carelessly and unfaithfully, the first edition of the collection of English historians which bears the name of Bishop Kennett. He himself wrote also A Critical History of England, 'The History of England during the reigns of the House of Stuart, and 'The History of England during the reigns of William and Mary, Anne, and George.' The two latter volumes are chiefly remarkable for their strong spirit of Whig partisanship. In criticism Oldixon was distinguished for his unscrupulous abuse of Pope and other eminent men of his day. He found abundance of material in the present, not only in contributions to periodical prints, but in his 'Prose Essay on Criticism,' and his 'Arts of Logic and Rhetoric' (a clumsy adaptation from Bouhours). His party-services were rewarded by an appointment in the place of Collector-general at the port of Bridgewater. He died in London, in 1742.

OMBROMETER. [Rain Gauge, P. C.] OMNIBUS. [Metropolitan Stage Carriage, P. C.] ONGA. (Ghana) was founded in the Sudan in 1924 at the entrance of a river of the same name, taken as an average, of the different stocks in which a loan is usually funded. Thus, a loan having been contracted for on a certain day, an average is made of the prices of these stocks in which a loan is desired, as the prices at which they bore on that day, and the fund thus formed as an average of the whole is called Ongam. (McCuiloch's Dict. of Commerce.)

ONGAR. [Essex, P. C. S.] ONGATAS ('Owron's) of Asine, the son of Micon, was alike distinguished as a painter and a sculptor; he was contemporary with Polygnotus, and lived according to the early historians, about the year 1800 B.C., and about the year 1700 of the Christian era. His name does not occur in Pliny, and, with the exception of an epigram upon a statue of Apollo by him, in the Greek Anthology, he is noticed only by Pausanias, a native of the place, who bore the name inscribed upon it, and who speaks in terms of great praise. Pausanias speaks a group of Homeric heroes near the great temple at Olympia, which were dedicated by the Achaeans in common; Thersites attributes them all to Onatas, the son of Onatas, or his name is inscribed on one only. Pausanias says that the Achaeans in common dedicated those statues which represent the Greeks who drew lots for the challenge of Hector; they stood armed with spear and shield near the great temple; opposite to them was Nestor with the lots in a helmet. There were eight besides Nestor; the statue of Ulysses, which made the ninth, had been removed by Nero to Bone. Of the remaining eight, five were dedicated by the Athenians, three by the Corinthians, and the seventh by Teutons, in terms of great praise. Pausanias speaks of a group of Homeric heroes near the great temple at Olympia, which were dedicated by the Achaeans in common; Thersites attributes them all to Onatas, but his name is inscribed on one only.

Pausanias mentions further, by Onatas at Olympia, a Mercury carrying a ram under his arm; he had on a helmet and a cloak besides a tunic or under robe; he was assisted by Callicteles, whom Pausanias supposed to have been the son or pupil of Onatas.

Onatas cast also in bronze a statue of Ceres the black, or Demeter Melaina, for the Phigalians, in the place of an old wooden image which was destroyed by fire. Onatas cast the new statue in a picture or wooden image, in the same way, assisted by a vision in a dream: it had a horse's head. He made also a statue of Apollo, at Pergamus, magnificent for its size and its workmanship.

Onatas, the bronze charioteer of Hero, dedicated by his son Deinomenes at Olympia in honour of his father's victories in the games: the horses and riders were by Callimachus. He made also, together with Calythus, an artist otherwise unknown, the monument dedicated by the 'Darellines at Delphi: they sent a tenth of the spoils taken from the Peucetii, a neighbouring barbarous people. The offerings consisted of several figures of warriors on foot and on horseback: Opis, king of the Danaeans, who assisted the Peucetii, was represented dying; near him stood the hero Taras, and Phalanthus, by whom was a dolphin; Phalanthus was saved from shipwreck in the Crisansea sea and brought on shore by a dolphin.

Onatas is mentioned only once as a painter: he decorated with Polygnotus the walls of the vestibule of the temple of Minerva Areia at Plataea. Onatas painted the first experiment of Titivages against Thersites. He probably also painted at Plataea the picture of Eurymas lamenting the death of her sons Eteocles and Polyneices killed by each other's hands; which, according to Sibylsburg, is by a MS. error, attributed to the other Greek artist, Ctesias, who bears the name. Thersites supposes Micon the father of Onatas to be the celebrated Athenian painter of that name.

(Pausanias, v. 26, 27, vili. 42, vi. 12, x. 18, ir. 5; Junius, the Lives of the Ancient Poets, to Thersites, Elegies der Bildenden Kunst unter den Griechen; Böttiger, Ideen zur Archäologie der Malerei.)
ONGOLE, or ANGOLE, a town of Hindustan, in the Presidency of Madras, and Northern Carnatic. [Carnatic, P. C. S.] Ongole is the chief town of the district of Ongole, and is situated in 15° 31' N. lat., 80° 1' E. long., 173 miles N. by W. from Madras. The sovereignty of the district and town of Ongole was acquired by the East India Company in 1815, but remained, with a few exceptions, unpossessed until 1853, when it was ceded by the native chiefs to the British. The town was then strongly fortified, but the fortifications have been suffered to fall into decay or have been destroyed.

(Atlas's "East India Gazetteer.")

ONGOHICHS (from *iwer, an ass, and *Dphw, to grasp the teeth), a genus of plants belonging to the natural order Leguminosae. It has a calyx with five nearly equal subulate teeth, a keel with uniformly truncate, longer than the wider, the pod one-seelled, compressed, indehiscent, one-seeded, upward straight, lower curved, toothed, winged or crested. The species of this genus are natives of Europe or Asia, with unequaly pinnate leaves, and axillary elongated peduncles having spines of flowers red or white at their tops. The most common, as well as only British species is *Onogorhics section, common Sainfinum. [Sainfin, P. C. S.; Hedstram, P. C. S.] About forty other species have been described, but none of them possess useful properties. Many are showy plants when in bloom, and are adapted for flower borders or rockwork. They may be propagated by seeds.

(Don's Gardener's Dictionary; Babington's Manual of British Botany.)

ONIONS (from *iwer, an ass, and *Dphw, to delight, of some the species being said to be grateful to ass's mouth), a genus of plants belonging to the natural order Hyacinthaceae. It is a herbaceous, annual, cleft campanulate calyx, narrow segments, the lower ones longer. The keel is beaked, the style filiform and ascending, the stigmas terminal and subcapitate.

(Don's Gardener's Dictionary; Babington's Manual of British Botany.)

O. anomala, growing in the opposite direction has a peculiar unifo rmly hairy stem, axillary stalked solitary flowers, broadly oblong leaves, ovate pods shorter than the calyx. It is usually without spines. The stems root at their base, and the seeds are tubercular and smooth in the plants.

(Don's Gardener's Dictionary; Babington's Manual of British Botany.)

O. arietis, a viscid pubescent stem, axillary flowers with one flowered pedicles shorter than the leaf flower, a pod without bracts, the corolla about equal to the calyx, obviate cuneate leaves serrated at the lip, ovate stipples, and cylindrical reflexed pods. It is found in sandy places in Galloway and on the Channel Isles, and in the south of France by the sea coast.

There are 107 species of this genus described, but none of them are used in medicine or the arts. They are chiefly native of Europe and Asia. All are annuals and a few on the coast of Asia. They are generally hand some when in flower. The hardy shrubby kinds are increased by seeds and layers, the hardy perennial kinds by dividing the roots in the spring, or by seeds. These are well fitted for flower borders. The seeds of the hardy annual kinds only require to be sown in the open border in April. The greenhouse and frame species thrive well in a mixture of loam, peat, and sand; these are usually increased by seeds which ripen in abundance.

(Don's Gardener's Dictionary; Babington's Manual of British Botany.)

ONGORDUM, a genus of plants belonging to the natural order Compositae. It has a honeycombed receptacle, a four ribbed fruit, and an imbricated involucre, with simple spinous pointed scales.

O. Acanthium, Cotton-Thistle, has an erect many-headed, elliptic-oblong leaves, woolly on both sides; serrate, spinous, and decurrent; the outer involucral scales lanceolate, subulate, recurved, and spreading. The stem is from four to five feet high, and has a short yellowish-green stem. The involu cre nearly globose, large, and somewhat cotonny; the scales fringed with spinous teeth; the florets are purple. This plant is found on waste ground in Great Britain and Spain, and another name for the same species is Wild Artichoke, or Alacacheta of the Spanish, on account of the flaky receptacle being once cultivated as an esculent vegetable. The expressed juice of this plant is said by Eller to be a serviceable medicine in the case of the breast, and to cleanse foul ulcers; and a decoction of the root, which is sanguineous, has been used to restrain discharges from the nervous member. The species of this genus have been examined as the result of experiments, that 22lbs. of onopordum heads will yield 12lbs. of seeds, from which 3lbs. of oil fit for burning may be extracted by heat.

(Babington's "Manual of British Botany")

ONOSMA (from *iwer, an ass, and *moua, smell; grateful to the ass), a genus of plants belonging to the natural order Boraginaceae. It has a five-parted calyx, a tubular campanulate corolla, and a naked throat. The anthers are siliate, and connected together by the bases of the lobes. The nuts are ovate, strong, and fixed to the bottom of the calyx, unperforated at the bases. The species are found in the United States, in woods, with crowded lanceolate or linear leaves, and terminal racemes of large yellow several and usually drooping flowers.

O. Emoidi has lanceolate tridented leaves, lesser hairy beneath, terminal solitary racemes, linear bracts, not half so long as the flowers; the calyx is five cornered with ovate segments, a verticose five-keeled corolla contracted towards the mouth, and the anthers longer than the filaments. It is native of Nepal, in Gosaingsthan, where it is called by the natives Mahomrav. The root is bronched, of a dark purple colour, and is used in dyeing.

O. echinatum is a huisp plant, covered with white punctate hairs. It is tropical and annual or biennial flowers. The corolla is yellow, a little longer than the calyx, tubularly campanulate with reflexed teeth.

O. innotorium is native of Tauria, in the vicinity of the Black Sea. The species is very hairy, the flowers are covered with a red pigment, which stains paper a violet colour.

All the species of this genus, which exceed thirty in number, are extremely handsome when in blossom, but are not valuable on account of any peculiar properties. Most of them are natives of rocks and sandy places in Europe and Asia, and answer well to grow in rock work or wall tops. They are short-lived, and apt to rot. They do well, however, in poor and small soil in other plants.

(Sturm, Lexicon; Hassel, Handbuch; Cannich, Lehrbuch.)

OPACITY is a condition of bodies incapable of transmitting light through them. It seems to depend upon the nature or disposition of the particles of bodies, but its precise cause is, at present, far from being understood. According to some, opacity may arise from the unequal densities of the particles of certain substances, in consequence of which the rays of light on entering those substances suffer such refractions and refractions as compel them there to reflect. It may be far further to be due to a density of the Atmospheric medium, in bodies of a homogeneous nature, as glass, diamond, &c., the light experiences so much less of these irregular actions that, except when the thickness of the medium is very great, it is enabled to pass quite through them.

The entire absorption of all the light which enters a substance, merely by the multiplied refractions or refractions which it undergoes within the mass, is difficult to conceive; and the advocates of the undulatory theory ascribe opacity to the unfitness of the pores, or intervals between the particles of a body, for permitting the vibrations of the particles of ether, and consequently for continuing in the interior the existence of the waves which are incident on its surface. The same persons consider transparency to consist in such a disposition of the particles of a body that the incident waves of ether can be propagated with a certain degree of freedom through the mass: some impediment to the propagation of the waves must exist in the most transparent substances; and hence when such substances have more than a certain thickness, the waves cease to be transmitted through them. [Transparrent, P. C. S.; Absorption of Light, P. C. S.]

OPERATION. This term we intend to point out the principal steps of the application of the calculus of operations [Operation, P. C.] to the solution of differential equations and equations of differences. This point must be carefully read before the present one, and also the general principles laid down in Algebra, P. C. S.

However much the calculus of operations may throw light upon the character and principles of algebra, application of it to the

Vol. II. — 3 C
time have been thought unlikely that it should much facilitate actual processes. It does this, nevertheless, and no where more than in the subject we are now going to describe.

Solutions which by the usual method (Variation of Parameters, P. C. S.) would never have been considered fit examples for an elementary work, on account of their complexity, may be represented with ease, and obtained in full with very little trouble.

When rules of algebra are true of the meanings of any symbols, all consequences of the use of these rules, all relations which are legitimate deductions from them, also represent truths. Not that these truths are always intelligible without subsequent interpretation. nor do we mean to say that, in the present state of the science, the interpretations are always attainable. And further, it may happen that theorems can be pointed out, derived from processes in which some only, and not all, of the fundamental rules of algebra are true. This does not prevent our right to deduce conclusions from such theorems, as long as we use no fundamental rules except those which are true of the expressions in question. For instance, we have seen that the operations of our calculus are not convertible with the operation of multiplying by a function of the variable. Thus if $E$ stand for the direction to change $x$ into $x+1$, $D$ for that of forming the difference arising, and $D$ for the direction to take the differential coefficient with respect to $x$, we have no right to say $$E\phi(x) = \phi(E(x)),$$ or $$D\phi(x) = \phi(D(x))$$ or $$D\phi (x) = \phi(D(x))$$ in which $\phi$ is the function operated upon. But we thus use another function, $D\phi$, beside the one operated on, $\phi$, this convertibility of operations is the only rule of algebra which falls; it is therefore the only one the use of which we must avoid.

The operations $E$, $\Delta$, and $D$ are closely connected with $E+\Delta+a$, $D+a$, of which they are particular cases; $a$ being a constant, positive, negative, or nothing. We have

$$E^{(a)} \phi(x) = a \phi(x+a),$$

$$(\Delta-a) \phi(x) = a \phi(a+\Delta(x)-\phi(x))$$

The first sides of these equations being representatives of $\phi(x+a)$ and $\phi(x)$, $E^{(a)} \phi(x)$ and $\Delta-a \phi(x)$, and $a \phi(x)$. If these operations be repeated, we have

$$E^{(a)} \phi(x) = a \phi(x+a),$$

$$(\Delta-a) \phi(x) = a \phi(a+\Delta(x)-\phi(x))$$

$$(\Delta-a) \phi(x) = a \phi(x+a)$$

These results will also be found to be true when $m$ is negative, by which means we are enabled to interpret $(\Delta-a)^{-1}$, $(\Delta-a)^{-1}$, and $(\Delta-a)$ and their repetitions.

These same forms may be extended, as follows:—Let $E_x$ and $E_y$ severally denote the operations of changing $x$ into $x+1$ and $y$ into $y+1$; and let $D_x, D_y, D_x, D_y$ be similarly interpreted with respect to the differentiations and differences.

We have then

$$E_x - a \phi(x) = (a+1)^{e^x} \Delta_x^a \phi(x)$$

$$(\Delta-a)(x) = (a^1)^{e^x} \Delta_x^a \phi(x)$$

$$(\Delta-a)(x) = (a^1)^{e^x} \Delta_x^a \phi(x)$$

$$(\Delta-a)(x) = (a^1)^{e^x} \Delta_x^a \phi(x)$$

$$(\Delta-a)(x) = (a^1)^{e^x} \Delta_x^a \phi(x)$$

in which the function first operated upon is left out to save room. Here $m$ and $a$ may be either positive or negative integers. And even $a$ or $b$ may be symbols of operation, but not with respect to $x$ or $y$. Thus

$$(D_a - a \phi(x) = e^{x b} E_a \phi(x) = e^{x b} \phi(x)$$

$$(D_a - a \phi(x) = e^{x b} E_a \phi(x) = e^{x b} \phi(x)$$

$$(D_a - a \phi(x) = e^{x b} E_a \phi(x) = e^{x b} \phi(x)$$

in which the second side is to be thus interpreted. Changing $y$ in place of $x$, differentiate as many times with respect to $x$, and then change $x$ into $y+1$. We shall now give the heads of some methods of solution, observing that this article is intended only for those who can already master the same solutions by other methods.

Take the common linear equation—

$$\frac{dy}{dx} + b \frac{dy}{dx} + c = 0$$

in which $a$ and $b$ are constants, and $x$ a function of $x$. The operation performed upon $y$ is $a \phi(x) + b \phi(x) + c$; if this is called $G$, then $y$ is the result of performing the inverse operation $G^{-1}$ upon $x$. By the method explained in Fractions, Decomposition of, P. C. S., transform $(a\phi(x) + b \phi(x) + c)^{-1}$ into $A(D-a)^{-1} + B(D-b)^{-1}$, &c., where $a, b, \phi(x)$ are the roots of the algebraical equation $a^2 - b^2 = 0$. Then is

$$A(D-a)^{-1} X + B(D-b)^{-1} X + c$$

or $A(a)^{-1} \phi(x) X + B(b)^{-1} \phi(x) X + c$, substituting for $D$ its usual mode of expression. The arbitrary parts of the solutions will be obtained by the constants of integration in the usual manner. But the arbitrary part will always be obtained in all inverse operations, by considering the function operated upon as $x+0$, and operating separately upon $x$ and 0. Thus $(D-a)^{-1} X$ may be completely expressed by

$$e^{x.a} = 1 + e^{x.b} = 0$$

the second term of which is $e^{x.\phi(x)} + e^{x.\phi(x)}$, $P$, $Q$, and $R$ being any constants.

Suppose that there are equal roots in the above equation, say three roots equal to $a$. The resolution of the fraction gives terms of the form

$$K(D-a)^{-1} X + L(D-a)^{-1} M(D-a)^{-1}$$

which contribute to the general value of $y$.

$$K(D-a)^{-1} X + L(D-a)^{-1} M(D-a)^{-1}$$

and the arbitrary part $e^{x.(P+Q+R)}$, $P$, $Q$, and $R$ being any constants.

Every single root $a$, contributes to the solution a term of the form

$$A(D-a)^{-1} X$$

in which $D-a X$ may be any function of which the difference is $a X$. If $a$ be an integer, what is called $X(a^2 X)$ will do. Any set of equal roots contributes terms of the form

$$A(D-a)^{-1} X$$

Any linear equation being given, in which either of the operations $E_x, D_y$, or $D_x$ is combined with either $E_y, D_y$, or $D_x$, the form of the solution may be found. Take for example

$$\frac{dy}{dx} + a \phi(x) + b \phi(x) = X$$

the operation performed upon $\phi(x)$ on the first side is $D_y - E_y$ and accordingly we have

$$w_x \phi(x) = e^{x b} \phi(x)$$

which is one form of the solution, and must be interpreted by expanding

$$e^{x b} \phi(x) = e^{x b} \phi(x)$$

Another form can be obtained from

$$E_y - D_y w_x \phi(x) = 0$$

We can only touch very briefly upon these points, and rather to show the existence of the system than to enter into it. Further details will be found in the Library of Useful Knowledge, in the 'Treatise on the Differential Calculus,' pp. 753-758.

The theorems answering to that of integration by parts, when $D$ and $E$ are used, are as follows. To save room let $D$ and $E$ be denoted by $\alpha$ and $\beta$. Then

$$e^{\alpha} (P\phi(x)) = e^{\beta} Q e^{\alpha} (P\phi(x))$$

$$e^{\alpha} (P\phi(x)) = e^{\beta} Q e^{\alpha} (P\phi(x))$$

$P$ and $Q$ being functions of $x$, to which $D$ and $E$ refer, and $P$ meaning $d^2 P/dx^2$. When $a=0$, the first becomes

$$\int P\phi(x) = \int P\phi(x)$$

which is the formula for integration by parts. And if $Q$ be of the form $Q \phi(x)$, or $Q \phi(x)$, and $P$ be a rational and integral function of a lower degree than the $w$, the preceding opera-
O.P.H

The obscure genus *R. elongated, Adder's genus

By help of these theorems the intermediate equations of any linear equation can be readily discovered. Suppose, for instance, we have

\[ (D-1)^2(D-2) y = x, \]

an equation of the eighth degree. There are eight of the seventh degree. Two of them are discovered at once by performing the operations \((D-1)^2\) and \((D-2)^2\) on both sides, giving

\[ (D-1)^2(D-2)^2 y = x^2, \]

\[ (D-1)^2(D-2)^2 y = x^2, \]

To find the other six, multiply separately by \(x, x^2, x^3, x^4\), the simplest of their several determinants, perform \((D-1)^2\) upon all four results, and \((D-2)^2\) upon the first two. This, by the preceding theorems, can be done.

Thus, multiplying by \(x\) we have

\[ (D-1)^2(D-2)^2 y = x^3, \]

\[ (D-2)^2(D-1)^2 y = x^3, \]

which are two more of the required equations. To find the equations of the sixth degree, those of the seventh degree must be selected which admit of a repetition of the operation, without leaving the inverse form \((D-2)^2\) or \((D-1)^2\) and the operation must be repeated; and so on.

(See the Cambridge Mathematical Journal, vol. iv., pages 60, 96. This work abounds in uses of the calculus of operations: it was here in fact that the late D. F. Gregory first introduced this branch of it. See also the Examples of the Differential Calculus, by the same author. Mr. Boole, in a recent volume of the Philosophical Transactions, has given very interesting extensions to the subject.)

O.P.HYDRIUM (from φυρα, a snake, and γυναικα, the tongue), a genus of malacopterous fishes of the Ela tribe. The species have smooth heads; long slender bodies, margined by the united dorsal, and caudal fins. The jaws, palate, and pharynx are all furnished with teeth. The branchial aperture is large. The species vary in form and colour, and in the presence, absence, and number of filamentous appendages or bars attached to the tail. They are distributed in the north and south poles, but both very rare. In the Mediterranean, the bearded ophidium is common, and is used for food.

O.P.HYXALEUS (from φυρα, a snake, and γυναικα, the tongue), a genus of fishes belonging to the division of Acant. thepsergii, characterised by having labyrinthine pharynxes, and capable of living for a long time out of the water. The species inhabit India and China. [ANABAS, P. C. S.]

O.P.HIOGLOSSUM (from φυρα, a snake, and γυναικα, the tongue), a genus of plants belonging to the natural order Filices and the tribe Ophioglossine. The theeae are comate, disposed in a simple distichous spike attached to an undivided frond.

O. vulgatum, Adder's Tongue, is the only British species. It has an ovate obtuse frond, and is from 4 to 12 inches in height. The spike is club-shaped, usually rather longer than the frond, sometimes very long. This plant is generally distributed over England, and in many places is exceedingly common, covering large plots of ground, and is highly injurious to the crop of grass. It is less frequent in Wales, Scotland, and Ireland. It is a common plant on the Continent of Europe, and is said to occur in Africa and North America. Like most singular-looking plants, it has been used in medicine. Ray recommends it as an elixir redissolved in oil and adder's-tongue. Gerardi says that the Adder's Tongue is dry in the third degree. The leaves of Adder's Tongue stamped in stone mortar and boiled in olive oil into the consumption of the juice and until the herbs be dry and perished, and then strained, will yield a most excellent green oyle or rather a balsame for green wounds comparable to oil of St.-John's-wort, if it do not far surpass it by many degrees, whose beauty is such that very many artists have thought the same to be mixed with verdigris. Lightfoot says that the common people in Scotland make an ointment of the green leaves, and use it as a vulnerary. It is also used in the same way in many parts of England.

(NEWMAN, BRITISH FAUNS; BABINGTON, Manual of British Botany.)

O.P.HIOXYLON (from φυρα, a serpent, and οξύς, wood, because it has a twisted root and stems), a genus of plants belonging to the natural order Apocynaceae. It has a 5-cleft permanent calyx, a funnel-shaped corolla with a long tube, thickest in the middle, and a 5-cleft oblique limb. The authors are subestinate. The tube is inserted into the middle of the ovary is double, each lobe with one ovule, a bilabium enclosed style and a capitulate stigma. The drupes are baccate, black, about the size of a pea, twin, or solitary by abortion, each containing a one-seeded wrinkled nut.

O. serpentinum, Serpentine Snake-Wood, is native of the East-Indies. In rich soil it becomes a climbing plant, but in poor soil it is a small creak shrub. The leaves are in threes or five; they are short-stalked, oblong, pointed, wavy, and smooth. The peduncles are long, smooth, round, sometimes nearly erect, sometimes drooping. The pedicels and calyces are of a bright red colour, and the corollas white. In India the root of this plant is employed by the physicians as a remedy in many diseases. It is given inwardly as a febrifuge and after the bite of poisonous animals. The juice is also expressed and dropped into the eye for the same purpose, and it is likewise used to remove tophi and ulcers of the face and cases of labour. This plant is of easy culture and beautiful appearance. A mixture of loam, peat and sand is the best soil, and cuttings will readily strike root under a glass in heat.

(Don, Gardener's Dictionary; Lindley, Flora Medica; Burnett, Outlines of Botany.)

O.P.HYSIS, a genus of plants belonging to the natural order Orchideae. It has a patent perianth, a variously-lobed lip without a spur, and the glands of the stalks of the pollen masses each in a distinct pouch.

O. opifera, Bee Orchis, has a tumid 5-lobed lip, the two lower lobes prominent and with a hairy base, the two intermediate reflexed, truncate, terminal, acute, elongated and reflexed; the anchors with a hooked point, the petals oblong, bluntish, downy. It is about a foot high, and has large, few, and rather distant flowers. The sepals are whitish edged with purple. The lip is velutiny, brown, variegated with yellow. It is one of the handsomest species of orchideaceous plants, native of Great Britain, and grows on chalky calcareous soils.

O. aractomites, late Spider Orchis, is distinguished by a terminal, inflexed, flat, rather heart-shaped appendage, and deltoid downy petals. The sepals are pink, the lip dark purple variegated with yellow and vellow, the appendage green, never reflexed. It is found on chalk downs near Folkstone and Sitlington in Kent.

O. transitoria, Spider Orchis, has 3 obaceous lobes, the middle lobe large, emarginate, without an appendage, the petals linear and hairy. This nectore is smaller than the preceding, and with fewer flowers. The petals and sepals are green and quite glabrous. The lip is of a dark brown colour, hairy, and covered with pale or yellowish lines. It is found in chalky places in Kent and Sussex.

O. nauseifera, Fly Orchis, has an oblong trifid lip with a large pale spot in the centre, the middle lobe is elongated, bialid, the anchors short and obtuse, and the petals filiform. It is a slender plant and grows about a foot high. The petals are very narrow, and of a purple colour, the sepals green, and the lip of a purplish brown colour, the spot in the centre of a bluish tinge. It is found in damp calcareous thickets and pastures in Great Britain.

(BABINGTON, Manual of British Botany.)

O.P. ORINIA, a genus of plants belonging to the natural order Compositae. It has a subular capitulum with a posterior scale much smaller in several rows, a penetrate receptacle, attenuated uniform fruit: the pappus of all the fruit in one row, festished, dilated at the base.

O. actuina, Tellus-leaved, linear, lanceolate, toothed, or pinnafilate, nearly glabrous; stalk branched, scaly, and thickened upwards, the involucrum glabrous or hairy. This is the *Aptopia actuina* of Smith, and the *Leontodon actuina* of Koch. It is a very great Brittan in meadows and pastures and on rocky mountains.

(BABINGTON, Manual of British Botany.)
OPT

OPONAX, a genus of plants belonging to the natural order Umbelliferae; it has an obsolete calyx, roundish entire petals rolled inwards, with a rather acute lobe; compressed ovate obovate segments, and bipyramidal less common with unequally cordate segments, created and obtuse. The umbels are compound; the involucre both universal and partial, and the flowers yellow.

The native of the south of Europe and Asia Minor, on dry hills, margins of fields, and thickets. It is a plant six or seven feet high, of a dull yellowish colour, and resembling a parlour. The stem is strongly curved; the leaves from one to two feet long, more or less, flat, bipinnate, ovate cordate leaflets, which are usually obsolete at the base, often constricted, and surrounded by a carmine-cordate border. The calyx is incommensurate, the style rather short and thick. This plant is a native of the south of Europe, the resinous gum which exudes from the stalk or root when wounded is brought from the Levant and East Indies in roundish drops of a reddish yellow colour, with specks of white. It is supposed to be an emmenagogue, but it is seldom used; it is similar in its effects to saffrole.

This is a plant of easy culture, and may be propagated either by seeds or dividing at the root.

(Don's Gardener's Dictionary; Lindley's Flora Medicinal.)

OPTOMETRIC (from the Greek oπομετρικος, to see, and προφορος, a measure) is an instrument devised for the purpose of ascertaining with precision the refractive powers of imperfect vision, whether a person's eye is myopic or hypermetropic, and to determine what refracting instrument would be most suitable for it. The idea originated with Scheiner; but such an instrument was constructed by Dr. Porterfield for the purposes just mentioned, and was afterwards improved by Dr. Thomas Young.

Dr. Porterfield's contrivance consisted of a convex glass lens fixed by its frame to a slip of wood about two feet long; a pencil of light, diverging from a radiant point in the axis of the lens, was suffered to fall on a plate of metal in which were two small perforations; and the rays which passed through these, after being refracted in the lens, were received on a screen, where they formed in general two bright spots, but in intermediate positions of the lens and screen the spots united as to form but one image. The distance of the single image from the lens, being measured by a scale of inches, constitutes the focal length of the lens for rays diverging from the radiant point. Dr. Porterfield used the instrument to determine the distance at which distinct vision of a small object takes place in the eye; the latter being substituted for the screen, to receive the rays coming from the object through the two perforations.

The instrument constructed by Dr. Young consisted of a slip of ivory, unpolished, or of wood covered with white paper, about eight inches long and half an inch broad, on which were drawn two lines of its length, with a narrow space or well-defined black line. At one extremity of the slip was fixed a plate of ivory, or a piece of card, nearly perpendicular to its length, and this was perforated either with a single small aperture or with two small apertures, on the distance of each varying from ⅛ to ⅓ of an inch, but not exceeding the diameter of the pupil of the eye.

On applying the eye to the single aperture, and looking in the direction of the line drawn on the instrument, the line appears to have a certain breadth, and to be ill defined, at the nearest extremity: the breadth gradually diminishes at points successively more remote till it becomes a minimum, when the line becomes distinct; beyond that point the line gradually increases in breadth, becoming again ill defined. On applying the eye to a double aperture, the line appears to be double, the part seeming to cease one another at a very acute angle, and the intersection is at the place where a single line would have had the minimum breadth; beyond this intersection the two lines appear to diverge from one another, and to become indistinct. The point of intersection is at which a single object being placed, its image would be distinctly seen by the eye at the aperture, and its distance from the eye may be immediately found by means of a scale of inches on the instrument, a sliding index being, at the time of making the observation, held opposite to the point of intersection.

This distance affords, evidently, a measure of the refractive power of the observer's eye; since rays of light diverging from a small object at that distance are, by the lenses of the eye, converged to form a distinct image in the retina, and to form there a single and well defined image. If the object were brought either nearer to or removed farther from the eye, the rays, after passing through the two apertures, would form two images, both of which would appear to be less perfectly defined than the single image.

It was supposed that a person whose sight is perfect sees a small object at a distance, and that the eye of the person will be true, as far as the eye is concerned, to a point of the object. Young, by computation a series of numbers which he placed on the scale of the optometer, at such distances from the plate containing the aperture, that a spectator having a perfect vision, a person whose vision is myopic, or one whose vision is myopic, or one which has distinct vision of small objects only when they are at greater distances than 8 inches) on looking through the slit and observing the place where the images of the two lenses met, would see the object at once, by the number at the place, the focal length of a convex lens which would enable him to see distinctly at 8 inches. He also computed a series of numbers which he placed on the optometer, which were to determine the virtual focus of a convex lens which would enable him to see distinctly at 8 inches. The optometer thus became a means of enabling persons to make choice of the proper lenses for spectacles which would correct the imperfections of their natural vision.

But the scale of Dr. Young's optometer being, for convenience, only 8 inches long, and the inferior limit of distinct vision in a presbyopic eye being beyond that distance, Dr. Young endeavoured to ascertain in what manner the eye accommodates itself to distinct vision for objects at different distances from it; and his conclusion was that the faculty depends entirely (Lectures on Natural Philosophy, vol. ii. pp. 570-603) upon changes of figure which take place in the crystaline lens.

ORCAGNA, or L'ARCAGNUOLO, is the name by which ANDREA DI CIONE, a celebrated old Florentine artist, is generally known; he is by llamohin Gençu, which appears to be his proper name. Vasari calls him Orcagna. He was painter, sculptor, and architect; was born at Florence in 1338, according to Vasari, or according to other sources at 1339. He was a pupil of Masaccio, and then of Doni, his most celebrated master, from whom he passed into the school of Andrea Penno. He painted several works, together with his brother Benvenuto di Andrea. In the latter part of his life he lived in Santa Fe, where he received in 1360 the last judgment. He was born at Florence, in the year 1380. He built also the church of the monastery of Or San Michele, and designed the celebrated tabernacle of the Virgin of that monastery. It is a high Gothic pyramid, with an altar to the Virgin, fixed on all sides, in a vault of white marble, and is richly ornamented with figures and other sculptures. The following works are inscribed on the base: Andrea Cione pictor Florentinus orariori archichrislorum extitit hujus MCCCLXXII, dedicated to the Blessed Virgin of the New Beginning. Florence, 1543. He was also a designer of monuments, for the Portinari, and for the Last Judgment and the Predestination. He was also the author of a work entitled Bo. G. Orcagna, 1543.
addressed to Orsagna. He died at Florence according to Vasari in 1389, but according to Muni in 1376.

He was a man of great taste in architecture, and has the credit of having been the first in those ages to adopt the British style, which required an act of legislation to be passed in the curia; but to this merit, if one, he is not entitled, though his elegant "Loggia de' Lanzi" may have contributed greatly towards the subsequent popularity of that form of the arch in Italy: Arnoldo di Paco, however, and his architect, have the credit of the semi-circular arch. Those, says Lanzi, who are fond of minute detail in minute things, may consult Baldincoci, Bottari, and Muni, concerning Andrea di Clone. Rumohr, however, was the first to show how reasonable a con- traiction, Lo Archangelou Lo 'rchagno l' archanghlo. in painting, Orsagna did not go beyond Giotto; in sculpture he was a worthy follower of the Pisan. According to his epitaph, which is given by Vasari in the first edition only of his work, he was chiefly excellent as a sculptor, or rather statutory.

His portrait, published in Vasari's work, was taken from one of the figures of the apostles in the above mentioned tabernacle of the Virgin, which is understood to be his own.

(Vasari, Vie de' Pittori, etc., and the Notes to Sonnini's translation of Vasari; Rumohr, Italiensche Forschungen.)

ORDER IN COUNCIL. This expression is chiefly known in connexion with the measures which the Great Powers took in 1807 and 1809, in retaliation of the Berlin and Milan decrees of Napoleon, by which Great Britain and her colonies were declared in a state of blockade. The measure of retaliation had the effect of transforming the Caroline islands into a place of execution.

During the war, the British government, with great prudence, decided to exercise the measure of blockade, rather by voluntary or by compulsion, gave obedience to the decrees. Full account of the matter will be found under the head Blockade, E.C. There has been much dispute as to the legality of these orders. The law of nations has acknowledged the blockading of lines of coast against the commerce even of neutral or friendly powers, when the object is to punish the state so blockaded, and the belligerent power has a force on the coast. The British government, however, had the coast, as well as the other coast of Holland. But where a belligerent power goes beyond this, and declares some place at which it has no armed force under a state of blockade, it simply issues an edict against the freedom of commerce, authorizes its cruisers to seize vessels which are not impeding any warlike operations, and covertly declares hostilities against the states affected by the fictitious blockade. The law of nations has never countenanced such a licence, and it came to be a question whether these orders in council, being thus not of an executive but of a legislative character, were legal, the Privy Council not having any legislative authority in this country, except so far as it may be authoritative upon the law of nations. It was maintained that they were merely part of the execution of the royal prerogative of declaring and conducting war, and that they were methods of legitimate retaliation, by which individual states were but as well as of their own subjects. Thus the measure of blockade, being an exercise of the royal prerogative during war, in prohibiting the supplying of the enemy with commodities contrary to war— an interference with the freedom of commerce justified by the necessity of the case. But these arguments did not satisfy the country generally that the measure, if it was a right one, should not have been accomplished by Act of Parliament instead of Order in Council.

It is difficult to draw the line between what may and what may not be accomplished by Order in Council. There have been various occasions on which, in cases of emergency, orders in council have been issued contrary to law, and those who have been concerned in passing, promulgating, or enforcing them have been tried to legislative protection, and taken on themselves the personal responsibility of the proceeding. In the year 1706, when there was a deficient harvest and the prospect of famine, an order in council was issued prohibiting the exportation of corn from Great Britain. To the immediate ensuing parliament the act 7 Geo. III. c. 7 was passed for indemnifying all persons who had advised the order or acted under it, and for giving compensation to all who had suffered by reason of that order. The same was done in 1874, when the order declared, which order could not be justified by law, but was so much for the service of the public, and so necessary for the safety and preservation of his majesty's subjects, that it ought to be justified by act of parliament. All orders restricting trade—unless they are within the justification of the national war policy—and all orders suspending the operation of any act of parliament, would require an act of legislation; but to this merit, if one, he is not entitled, though his elegant 'Loggia de' Lanzi' may have contributed greatly towards the subsequent popularity of that form of the arch in Italy: Arnoldo di Paco, however, and his architect, have the credit of the semi-circular arch. Those, says Lanzi, who are fond of minute detail in minute things, may consult Baldincoci, Bottari, and Muni, concerning Andrea di Clone. Rumohr, however, was the first to show how reasonable a con-
The following are romances.

Lorenzo Malcondo ... Spanish 1588
Juan de Fuca ... 1592 Proposed to have discovered the North-west passage by sailing through the Continent of North America.

Fonte, or De Fuentes ... Spanish 1640. 77°.

This last is a palpable forgery, and was first published in 1706, in London, by the well-known Miscellaneous, Memoirs of the Curious. Neither Fuentes nor Fuca was ever noticed by Spanish writers. Fuca invented his story with a view of getting commissions from English; Fuentes never did anything but write.

Hukley, in his ‘Collection of Voyages,’ published in 1599, states that Drake merely reached the lat. 42°, but his account is interpolated in the volume which contains it, and he appears to have intended to suppress it. In the edition of 1600 he places the northern point of Drake’s voyage in latitude 45°.

The authorities for the higher latitude are: 1. ‘The World Encompassed,’ printed in 1628, under the superintendence of Francis Drake, a nephew of the admiral, which states that the coast ‘was searched diligently even unto 45°’. 2dly, Fletcher, who accompanied Drake, and whose MS. is in the British Museum. 3dly, the celebrated navigator John Davis, in ‘The World’s Hydrographical Discovery,’ printed in 1626, says, that Sir F. Drake ‘coasted all the Western shores of America until he came in the septentrional latitude of forty-eight degrees, being on the back side of Newfoundland.’ An authority which ought to decide the question; and yet the limit of Drake’s discoveries, 4thly, Admiral Sir W. Monson, who had served under Drake, and who says that Drake ‘ventured upon an unknown sea in forty-eight degrees.’

The Spanish explorations in the Pacific, 1781, published under the name of Fonte, Valdes, and Valdes, published by the order of the King of Spain, at Madrid, in 1802, is this passage—‘The true glory which the English navigator (Drake) may claim for himself is, the having discovered the portion of coast comprehended between the parallels of 43° and 48°, to which consequently the name of New Albion ought to be limited, without interfering with the discoveries of preceding navigators.’

The discovery of the coast was, therefore, made by the British. But even if Drake had not discovered it, still, according to the principles laid down by jurists, the exploration of Cook would be ranked as confirming, since the voyages of Peres Hecquet and Bodega were not made known until 1802. (Wolf, ‘Institutes du Droit des Gens,’ p. 213; Vattel, book I. l. xvii. § 207.) The discovery must be made public, otherwise the presumption is against it, or that it was a mere passing act, or that occupation not being intended, the territory was abandoned. Publicity is essential to entitle foreign nations to recognise and respect the title first obtained.

Such was the condition of the title by mere discovery when the Spanish officer, Captain Martines, in May, 1786, seized the British vessels the ‘Iphigenia,’ ‘North-West America,’ and the ‘Lady’ the ‘Argonaut,’ Captain Colnett, and the ‘Princess Royal.’ A correspondence ensued between the governments of Great Britain and Spain, which occasioned a message from the king to both Houses of Parliament. delivered May 25, 1790, stating that ‘no satisfaction was made or offered for the acts of seizure, and that a direct claim was asserted by the court of Spain to the exclusive rights of sovereignty, navigation, and commerce in the territories, coasts, and seas in that part of the world.’ The claim of sovereignty was asserted by Spain objects to, and Mr. Pitt stated that ‘it was indefensible in its extent, and had originated in no treaty nor formal establishment of a colony, nor rested on any of those grounds on which claims of sovereignty, navigation, and commerce usually rested.’

This dispute was terminated by the Convention of the Escural, dated October 28, 1790, the third article of which declared that ‘the respective subjects of the contracting parties should not be molested in navigating or carrying on their fisheries in the Pacific Ocean or in the South Seas, or in landing on the coasts of those seas in places not already occupied, for the purpose of carrying on their commerce with the natives of the country, or of making settlements there.’

Great Britain then renounced its title to exclusive possession, founded on mere discovery—and any similar claim on the part of Spain was abandoned. The Convention was condemned by the opposition in parliament, the chief speakers asserting that Great Britain ought to have excluded Spain, and not to have conceded to it the right to settle on the coast. When it was asked whether Pitts could be made to do it, he should esteem the government highly culpable if it neglected to ascertain by actual survey.

Captain Vancouver was sent by the British government to take possession of Nootka Sound, and to ascertain the things how far to the north Spanish settlements had been established. He sailed from Deptford, January 6, 1791. Nootka Sound was delivered to him, but having a discussion on the extent of his instructions with the Spanish officers at Quadra, Lieut. Mudge was sent to England for further orders. Ultimately, in March, 1795, Nootka was delivered up to Lieut. Pierre of the marines.

It was while Vancouver was on this voyage that he received information that in May, 1792, Captain Gray, of the ship Columbia, from Boston, had entered the estuary of the river now known by the name of this ship. Vancouver had on the 27th of April observed the ‘river-coloured’ to the north, but he did not attempt to enter the river in consequence of being directed by his instructions not to pursue any other inlet or river than should be navigable by vessels of a burthen safely to navigate the Pacific. Shortly afterwards Lieut. Broughton in the Chatham, the consort of Vancouver’s vessel, entered the estuary, and found there the ‘Jenny’ of Bristol, Captain Baker, who had been there before in the early part of the year. Lieut. B. explored the estuary, discovered where the river entered it, which Gray had not done, and ascended the river above 100 miles—taking possession in the name of his sovereign. Gray, it must be observed, was a mere private trader, who was sent from his Government with the express charge of having been previously discovered, and his own government never noticed his proceedings until 1814. But if he had had a commission, the discovery of the entrance to the river was a mere spy on the geography of this region. The British Government under General Sir George Prevost demanded possession of the title to the coast, and their discovery does not affect or impair such a title.

After Nootka Sound was delivered up in 1790, the Spanish never made any settlement north of Cape Mendocino. They abandoned the country, and left the British to perfect their title by discovery, through occupation and settlement.

The subsequent expeditions to Oregon were as follows—

Name of Traveller. Flag. Date. Itinerary.

George Vancouver ... English 1793. Crossed the Rocky Mountains and discovered Fraser’s River.

Lieutenant David Thompson ... English 1806. First Settlement West of the Rocky Mountains in 54°, speedily followed by other settlements among the head-waters of Columbia.

Lieutenant Lewis and Clarke ... Americque 1804-5. Explored the Southern branch of the Missouri, the Yellowstone, and descended the main stream.
ORE 383

Astor's Company. American. 1811. Established Astoria, at the Southern mouth of the Columbia, which was subsequently sold to the North-West Company.

Thompson, North-West Co. English. 1811. Descended the Northern branch of the Columbia and main stream to the mouth.

The expedition of Mackenzie was the first made by civilized men west of the Rocky Mountains.

The posts and settlements made by Thompson were the first established by civilized men west of the Rocky Mountains, and Thompson and his followers were the first white persons who navigated the northern branch of the Columbia or traversed any part of the country drained by this branch of the river.

Astor's Pacific Fur Company consisted of Mr. Astor himself, six British subjects, and three citizens of the United States. Before those who were British subjects started, they asked for and received an assurance from the British minister at Wash-ington—that in case of a war between the United States and Great Britain, they would be respected as British subjects and merchants. The expedition received no sanction or support from the government of the United States. In 1818, the persons resident on the Columbia, having full power to do so, sold their establishment to the North-West Company. Subsequently in the same year, Captain Black, R.N., in the Raccoon, took possession of Astoria in the name of his Britannic Majesty.

After the war the American government claimed Astoria, under article of the Treaty of Ghent, made in December 1814, as a post captured during the war. This was not the fact; but in 1816 possession was formally delivered up, the British government being prevailed on to the post as not being captured, and that the treaty had already been taken possession of in his majesty's name (as it had been by Broughton); but that the question of title should be discussed in the negotiation on limits and other matters, which was soon to be commenced. (Greenhow, 307, 310, 312.)

On the delivery of this post the United States for the first time exercised any act of sovereignty in Oregon. It was put into possession, but not relieved from proving its title, for its possession was derived from Great Britain.

In October, 1818, a treaty between Great Britain and the United States declared that the country should be open to the free intercourse of both nations, to settle the claims of either power or to the claims of any other power. In February, 1819, the United States made the Florida Treaty with Spain, which declared part of the west boundary of the United States to be the Mississippi River, the sea, and the states to the sea, both parties ceding to each other, and respectively renouncing, all claims on either side of this line. The Americans pretend that this treaty conferred a title to the coast north of 49°, though Spain never completed or obtained a title by occupation.

In August, 1827, a treaty between Great Britain and the United States extended indefinitely the provisions of the treaty of 1818, until determined by notice of a year, and it was not to impair the claims of either party. This treaty was still in force, but the Congress of the United States in April 1846, authorised the notice to terminate it to be given.

1. The government of the United States contended, notwithstanding their treaty of 1818, that Spain alone was entitled to Oregon until 1819. In reply it is said that the British title was acknowledged by the Convention of the Escorial—that Spain never made a settlement in the territory, but totally abandoned it—that Spain had no title either by discovery or occupation—that all the rights or claims which it had were derivable from the treaty of 1790—and that official Spanish writers admit the British title by discovery as correct. It is held that the Oregon branch is not a private person, extend the territory of the United States—

that his discovery was never noticed by his own government for upwards of twenty years—and that in the negotiation with Spain in 1819 it was not set forth.

3. The settlement of Astoria is called a national settlement. In reply it is said that the only sanction the adventurers received was from the British, and that the British merely private speculation by a party of men, the majority of whom were British subjects, who had asked for British protection—that the application to the United States government to sanction the enterprise was declined with a view that the enterprise could not be planted beyond the limits of the United States without the authority of an Act of Congress.

The British title depends on original discoveries made by Drake, Cook, and Nelson, whose title was sanctioned and approved of by their sovereigns, and notified to the world—on the acknowledgment of the title made by Spain in 1790—on the resumption of Nootka in 1795, as evidence of the acknowledgment of territorial rights—on the possession taken by British officers, which by our law, when done with the sanction of the sovereign, is alone sufficient to make a country part of the dominions of the crown—on the numerous settlements and posts which our government has allowed the North-West Company and the Hudson's Bay Company to establish—on the recognition of the claims of the British government made by the United States in 1814, in 1816, and in 1827—that the treaty with Spain was respected, and which was recognised by the United States before its treaty with Spain in 1818, as well as subsequently in the treaty of 1837.

Great Britain cannot assert claims beyond the terms of the treaty of 1790. The United States some time since claimed the whole territory, without ever having obtained any legal authority over any part of it, and they now allege the extent of this bare claim as evidence of having a better title.

In the course of the early negotiations the United States government offered the boundary of 49° to the sea and the navigation of the Columbia river. Great Britain required that the line should run along 49° to the Columbia river, then along the Columbia river to the sea, agreeing not to erect any fort at the mouth of the river. Subsequently it offered part of the territory between the Columbia and the river. In the last negotiation carried on by Mr. Pakenham and Mr. Buchanan, the United States offered a boundary along the parallel 49°, withdrawing the former proposal respecting the Columbia river; and the correspondence closed with an assertion of an exclusive right to the entire west coast from 49° to 54° 40', thus denying every claim made by Great Britain and hitherto recognised by the government of the United States. There are signs that this violent policy and disregard of the admissions made in former negotiations will not be supported by the people of America, and it is to be hoped that they will not be indifferent to what is just and right. The inhabitants of the United States have been offered to refer the question to arbitration, and the last offer was very reasonable for proposing that the arbiters should be civilians, in order to avoid the apprehension which republicans might have of a military tribunal. The offer has been refused, and the last refusal was accompanied with most objectionable reasons.

OREGODAPHNE, Mountain Laurel (from oregus, mountainous, and laurus, a laurel), a genus of plants belonging to the natural order Lauraces. It is known by its flowers, each with 6-parted nearly equal calyx, the limb eventually disappearing. It has 5 stamens, oblong anthers, with narrow filaments, 4-celled, the 3 inner looking outwards. The fruit is succulent, more or less immersed in the expanded tube of the calyx. The flowers are panicked or racemose, axillary, and occasionally umbellate. O. opusflora is native of the woods of Fan and the Rio Negro. It has 2 oval leaves, pale ochraceous when young. O. cupularis is a very large tree, with a strong-scented
wood; it has ovate, toothed, leaves, acute at both ends, sometimes
sitting, ending in a channelled stalk, ob-
ately notched, smooth; the axes of the coastal veins without
pores. The flowers are in clustered few-flowered rough hoary
vivaces below the axillary and terminal bud. The calyx of the
fruit has three of the placenta, which is the character of the
Ist of France, where it grows, and also in Bourbon and
Malagascar.

(Lindley, Planta Medicin.)

ORGANIC CHEMISTRY. [TURBIA, ANIMAL, P.C.S.] 

ORGANON. The article ORGANON in the F. C. con-
tains a general view of the nature and object of logical science;
and the article SYLLOGISM contains all that is necessary on that
subject. They will help anyone is still wanted to complete
what has been already given.

The 'Elementa Logicae Aristotelicae,' by Professor Tren-
denbourg, Berlin, 1842, 2nd edition, consists of passages se-
lected from the works of Aristotle, which passages may be con-
sidered as containing the elements of the science. Those
passages are so arranged as to present a kind of outline of the
whole logical system of Aristotle. They are intended for the
use of the higher classes in gymnasium, and as a preparation for
philosophical studies.

The following article is simply a translation of these ex-
tracts, which are retained in the order given to them by Tren-
denbourg, with references to the places in Aristotle which
have also been retained. The original terms of Aristotle
are also given in brackets the first time that each is mentioned.

In the preface to another useful work (Erleutertungen zu den
Aristoteles'sen Logiken, Berlin, 1842, signed by the same author),
he has more fully explained his views in making
these extracts from Aristotle, and the following re-
marks are his: At the time of the Reformation Luther
saw clearly the advantage of logical instruction in the
high schools, and he viewed it correctly as the completion of the
grammarical instruction. The circle of studies in modern
times has been wonderfully enlarged, and it has been found
necessary to give a distinct school instruction to meet the wants
of the present age. But the great variety of subjects with
which our present systems of education occupy us, only
render it the more necessary to discipline the mind in such
manner as to see a unity in all the powers, and
not be bewildered by the variety of objects whose connec-
tion escapes us, when they are contemplated separately.
Such a discipline is furnished by a good course of elementary
instruction in logic. For this purpose the author has adopted
the genuine words of Aristotle, in which the philosopher has
laid down his elementary logical principles. The logic of
Aristotle is not antiquated, though it is both misunderstood by
some, and blamed by others who do understand it. It is
not the formal logic of Kant, which would confine us to the
forms of thought without any reference to the object into
which the thought penetrates. Such a limitation of the sub-
ject to a form of logic, the same with the, and opposed to its
real character. 'We have,' says Trenendenburg,
'trumped to restore this real character, and thus
brought Aristotle nearer to the objective demands of modern
times.' This view logic as purely formal, view it
differently from Aristotle, and they may consider their mode
of viewing the subject to be better than his. Those who say
that Aristotle has, in some matters, erroneously extended
the province of logic to things beyond its limits, and has not always
kept close to the real subject, appear to have conceived that
he viewed it merely as formal, and sometimes transgressed
the boundaries of the science which he recognized. This
is however an erroneous view of Aristotle's system.

The advantage of studying these elementary principles in
the words of Aristotle is, that in his writings the language
of philosophy is formed into a scientific terminology, which is
the basis of that which we now use. We cannot therefore
lay a better foundation for our logical and philosophical studies
on any other basis than a full comprehension of the meaning
of Aristotle's terms.

The author remarks that a learner of logic there meets
with a mass of connected notions (begriffe) in their simple naked-
ness, which lie hidden in all our knowledge and govern it.
As these notions are hid or concealed in our knowledge, they
appear dry and lifeless when they are produced in their naked
form, unless the teacher has to show them to the pupil their
real significance, to make him see their actual value in their
application. Now the instruction in the Ger-
man Gymnasium, as in the higher schools in Great Britain
and Ireland, is in the learned languages and to mathematicians;
and accordingly the teachers in both these departments, if they are
to be making any useful work as Trenendenburg's, must be able to
apply logical principles to instruction in language and in
mathematics. To facilitate this method of instruction is the object
of the learned author in the illustrations (Enlärkungen) to
the Elements of Logic. He says: 'This is precisely the form in
which I suppose that they ought to be presented to the pupil, but
merely to render clear the fundamental notion of the logical relativeness in the objects
of scientific observation.'

The mode in which the author suggests that his two works
should be used is probably the best; but they cannot be used at
all in ordinary instruction, except under the guidance of
a competent teacher. The student will need a man who
has a competent knowledge of the Greek and German
languages, and possess some elementary notions of logic;
and those who cannot read Greek with facility will probably
find the following translation sufficiently exact to give them
the meaning of Aristotle. A translation of such extracts is
not easy, and it is possible that there may be some errors in it.
A careful study of these extracts however will convince a
student how meagre and unsatisfactory an exhibition of the
elementary principles of logic even our best works on the
subject contain.

Outlines of Logic.

(1.) In things in which formal is as much falsehood and truth,
there is a composition of ideas as though they were one. (De
Annis. iii. 6.) For falsehood and truth are concerned
with composition and separation. Accordingly nouns and verbs
are opposed to each other: 'This man,' 'I,' 'the verb.'

(2.) All speech (λόγος) is significant, but not all enunciative
(διηγήσεως), or significative, or every enunciative speech
true or falsehood. But it is not in all: for example, prayer
is speech, but neither true nor false. The enunciative
alone belongs to the present inquiry. (De Interpr. c. 4.)

(3.) Speech is enunciative, or signifies either substance (οὐσία)
or quantity, or quality, or relation, or where
(space), or when (time), or position, or possession, or acting,
or being acted upon. And substance (οὐσία) is, to give an
example, such as 'man,' 'horse,' 'quantity,' 'quantity,
such as two cubits, three cubits: and quality, such as
white, grammatical: and relation, such as double, half,
and where, such as in the Lyceum, in the aerop: and when,
such as yesterday, the next year; possession, such as he is
sitting: and possession, such as he has shoes on, he is
armed: and action, such as he cuts, he burns: and being acted
upon (συνέκτημα), such as he is cut, he is burnt. (Catug. c. 4.)

(4.) The art of the undifferentiated

(5.) 'Not-man' is not a noun; for indeed there is no name
to call it by; for it is neither affirmative speech nor a negation.
But let it be called 'name or noun indiscriminate,' because it
may be said equally of anything, both of what is and what is not.
Every affirmation and negation will consist either of a noun
and a verb or of an indefinite noun and a verb. But without
a noun, there is neither affirmation nor negation. (De Interpr. c. 2. 10.)

(6.) Of things some are universal and some particular. I call
that universal which can be said of more things (than one);
and I call that particular which cannot: thus, man belongs
to the universal, and Callias to the particular. (De Interpr. c. 5.
A Proposition (πράττον) then is speech either affirming or
denying something about something. And this speech is
either universal or particular or indefinite. I call that
universal which belongs either to all or to none, and that
particular which belongs either to some one, or to not some one,
or not to all; and I call that indefinite which either belongs
do not belong, without the universal or particular, as, for
instance, what is placed below this science; and that
pleasure is not a good. (Analyst. Pr. i. 1.)

It is very evident that the universal is more efficient, be-
cause, knowing the first of two propositions we know in a
manner the second also and have it potentially; for example,
If a man knows that the angles of every triangle are together equal to two right angles, and that the single or the angles of an isosceles triangle also are together equal to right angles potentially (tornai), even if he do not know that the isosceles triangle is a triangle. But he who knows this proposition and of the affirmative proposition, either universally or potentially or in reality (tornai). And the universal is an object of the intellect, but the particular terminates in the sensuous perception. (Analyst. Post. i. 24.)

(7.) Whatever is, or to what must be, or to what can be, is. (Analyst. Pr. i. 2.)

(8.) Of all things indeed which exist there are some of such a kind that they can be predicated with truth universally of nothing else but the single thing, and what is an object of some; but of these things others can be predicated (for each of these persons is both man and animal); and some things are themselves predicated of other things, but of them there is no further predication by other things; and some are both themselves predicated of others, and others of them, for example, 'man' is predicated of 'Callias,' and 'animal' of 'man.' Accordingly that there are some things which exist cannot be predicated of anything is manifest. For of sensuous objects nearly every one is such that it can be predicated (propagredous) of nothing. (Analyst. Pr. i. 27.)

The genera are predicated of the species, but not the converse, the species of the genera. (Categ. e. 5.)

(9.) It is impossible for the same thing at the same time to belong (avitréous) and not to belong to the same thing and in the same manner. For if the earth move, we would have the most certain; for it is impossible for any one to conceive that the same thing is and is not. Wherefore all who demonstrate, can neglect (their demonstration) to this ultimate notion. (Metaphy. iv. 3.)

Every thing which is true must agree with itself in every way: for with truth all which is true is in harmony, but with falsehood the truth is at variance. (Eth. Nic. i. 8.)

(10.) And since it is possible for what belongs to be enunciated as not belonging, and what does not as belonging, and what does both belong, and what does not long as not belonging, and with respect to other things than the present in like manner, it is possible to deny both all that a man has affirmed, and to affirm what he has denied. So that it is manifest that to every affirmation a negation is opposed; and to every negation an affirmation; and let the contradiction (avitréous) be this, affirmations and negations opposed. And I call opposition (dilxestelas) the contradiction of the same thing about the same thing, but not opposite. (Comp. Categ. e. 1; De Interp. e. 6.)

Contradiction is opposition (avétrin) in which there is no mean in itself. And as parts of contradiction, there is on one side the affirmative, and on the other side the negative, and knowing something from (kiv) something. (Analyst. Pr. i. 2.)

In affirmation and negation always, whether it is a thing that exists or does not exist, the one will be false and the other true, or the one true and the other false, and the universal Socrates is not sick, when Socrates exists it is manifest that one of them is true and the other false, and if he does not exist in the same manner: for that he is sick, when he does not exist, is false, and that he is not sick is true. Accordingly, to these things alone, which are opposed as affirmation and negation, it will be peculiar for one of them always to be true or false. (Categ. e. 10.)

(11.) Things included under the same genus which differ most from one another, are defined to be contrary (tivr'do) (Categ. e. 6.)

(12.) Therefore I say that affirmation is opposed to negation in the way of contradiction, when the one signifies that a thing is universal and the other signifies that the same is not universal: as for example, every man is white—not every man is white; no man is white—a certain man is white. And I say that the universal affirmation and negation are opposed as contraries: as for example, every man is white—no man is white; every man is just—no man is just. Therefore it is not possible for these to be true at the same time. (De Interp. c. 7.)

(13.) And I say that propositions opposed are in the same expression (eita koiito) four—namely, all and none, all and some, many and none, some and none; but in truth there is for some is opposed to not some merely in expression. And of these three propositions the universal, all and none, are contrary: for example, all knowledge is excellent, no knowledge is excellent; but the other propositions are opposed (as contradictory). (Analyst. Pr. i. 15.)

(14.) And since every proposition is either of being or of necessarily being or of the possibility of being, and of these some are affirmative and some negative in every mode, and again of the affirmative propositions some are universal and some particular and some indefinite, of necessity the proposition which is universally negative can be converted (avtropia) in its terms (Eos): for example, if no pleasure is a good thing, neither is any good thing pleasure; but the affirmative proposition must be converted, not indeed universally but particularly; thus if all pleasure is good, some good also is pleasure. And of particular propositions the affirmative propositions are invariable particularly, for if some pleasure is good, some good also is pleasure: but as to the negative, it is not of necessity, for, if 'man' does not belong to (cannot be predicated of) some animal, it does not follow that 'animal' cannot be predicated of 'man.' (Analyst. Pr. i. 2.)

(15.) The things which are sought are equal in number to the things which we know. And we seek four things—the That, the Why, If it is, What it is. For when we consider whether this or that is, referring it to number, for example, whether the sun is eclipsed or not, we seek the That. And there is proof of this; for when we have found out that it is eclipsed we cease reasoning; and if from the beginning we know that it is eclipsed, we do not inquire whether it is. And when we know that it is, we inquire the Why: for example, when we know that the sun is eclipsed and that the earth moves, we ask why the earth moves. These things accordingly we inquire after thus; but some things we inquire after in another manner, as for example, whether there is or is not God. (Categ. c. 8.)

simply mean if there is or is not, but if he is white or not. And when we know that there is, we inquire what it is, for example, What is God or what is man. (Analyst. Post. iii. 1.)

(16.) To know that a thing is and to know why it is are different; and the knowledge of the Why refers to the first cause. The chiefest of knowledge is to contemplate the things which are and to know the Why. (Analyst. Post. ii. 19.)

(17.) And we think that we know each thing simply when we think that we both know the cause by which the thing is, that it is its cause, and that it cannot be otherwise. (Analyst. Post. i. 2.)

(18.) All instruction and all rational learning come from knowledge preceding. And this is manifest to them who contemplate all (sciences); for both those of the sciences which are mathematical by these means exist, and every one of the other arts. (Analyst. Post. i. 1.)

(19.) And things are prior and better known in two ways: for it is not the same thing to be prior by nature and prior as we know them, which is more known. And we are acquainted with, and know by us. And I call those things prior and more known as regards us which are nearer the sense, but I call simply prior and more known those things which are further from the sense, and are not the same as the former, and the nearest are the particular. (Analyst. Post. i. 2.)

(20.) We get certainty in all things either by syllogism (syllogismos) or by induction (inveni). (Analyst. Pr. ii. 28.)

We learn either by induction or demonstration (diketosis) and demonstration proceeds from the general, but induction from the particular. (Analyst. Post. i. 13.)

(21.) And syllogism is in which when some things are laid down, something else different from what are laid down results by virtue of their being laid down; and by virtue of their being laid down. And I mean by results through them; and I mean by results through them, that there is need of any external term for the necessity to be. (Analyst. Pr. i. 1.)

(22.) And I call Term that into which the proposition is resolved, as the predicate and the thing of which it is predicated (subject). (Analyst. Pr. i. 1.)

(23.) Whosoever is affirmed of the predicate, will be affirmed of the subject. (Categ. c. 11.)

(24.) When three terms are so related to one another that the last is in the whole of the middle, and the middle is in either or not in the whole of the first, of necessity there is no term, some and none of the extremes are equal; and I call middle that which is both itself in another and another in it, and which also by position becomes middle; and I call extremes both that which is in another, and in which another

VOL. I.-8 D
is. If A can be predicated of all B, and B of all C, necessarily A can be predicated of all C. And I call a figure (ευθέως) of such description the first. (Analyt. Pr. i. 4.)

(25.) And when the same thing belongs to all of one thing and to none of another, or to all or none of each, such a figure I call the second, and that which is predicated of both, or neither, when the middle term is placed without the extremes (δεκας), but the first in position —And a syllogism will be possible both when the terms are universal and when they are not universal. When they are universal, it will be a syllogism, in which one or another, or both of them, if it be in one, and in none of the other, if the negative be in one of the two terms: but otherwise the syllogism cannot be.

For let M be predicated of no part of N, but of all X. Since then the negative proposition can be converted, N will belong to no part of M: but M by the supposition was predicated of all X. Accordingly N will be no part of X: for this has been shown before. Again, if M shall belong to all N, but to no part of X, neither will N belong to any part of X: for if M belongs to no part of X, neither will X belong to any part of M: but M by the supposition belongs to all N. Therefore X will belong to no part of N: for this also has become the first figure. And since the negative proposition is convertible, neither will N belong to any part of X, so that there will be the same syllogism. An affirmative syllogism is not produced by means of this figure, but a syllogism belongs to the universal affirmative syllogisms and the particular syllogisms. (Analyt. i. 5.)

(26.) But if one thing belongs to the whole of the same thing and another belongs to no part of it, or both to the whole of the same, but such a figure I call the third; and if the middle term be thought of in it of which both the predications are made, I call I the extremes the predicates: And the middle is placed without the extremes, and last in position. And a syllogism will be possible both when the terms are universal and when not universal with reference to the middle.

Accordingly if they are universal, when both P and L belong to all S, S will belong to some part of R of necessity, if the affirmative is convertible, S will belong to some part of R, so that since P belongs to all of S, and S to some part of R, of necessity P belongs to some part of R: for the syllogism is produced by means of the first figure.

To form a syllogism universally by means of this figure is not possible, neither in the negative nor in the affirmative. (Analyt. Pr. i. 6.)

(27.) And it is manifest that every demonstration will be by means of three terms and not more. And since this is clear, it is manifest that it consists of two propositions and not more: for the three terms are two propositions. (Analyt. Pr. i. 28.)

(28.) It is necessary in all the figures that the middle be in both in the propositions. If then the middle term both predicate and be the subject of predication, or itself predicated and subject, if it be the same term, it will be the middle figure: and if other things are predicated of it, or one thing is denied and another predicated, it will be the last figure.

(29.) Moreover in all syllogisms one of the terms must be affirmative and it must be universal: for without the universal there will either be no syllogism, or it will not relate to the thing proposed, or the very thing to be proved will be assumed. For let it be proposed to prove that music is an honourable pleasure; if then any one should assume that pleasure is honourable, holding the all, it will not be a syllogism: and if he should assume that music is excellent, if he means other pleasure, it has nothing to do with the subject proposed, and if he means the very pleasure itself, he assumes the very thing which is to be proved. (Analyt. Pr. i. 24.)

(30.) The science of what a thing is, it is possible to investigate by means of this figure alone (the first). For in the middle figure the syllogism is not affirmative, and (the question) what science is, requires the affirmative: and in the last figure there is a syllogism, but not a universal syllogism, and the question what a thing is, belongs to the universal. (Analyt. Pr. i. 21.)

(31.) All who attempt to syllogize from things less credible than the conclusion, manifestly do not syllogize rightly. (Top. vii. 5.)

(32.) If what is true is not possible to form a false conclusion, but what is false is it possible to form a true conclusion; not however 'why' but 'that' the thing is. (Analyt. Pr. ii. 2.) Accordingly it is manifest that, if the conclusion be false, of necessity those things are false either wholly or partly, or both. The argumentation (epainetois) of Socrates is derived: but when the conclusion is true, it is not a matter of necessity for either anything or all to be true, but it is possible when none of the things in the syllogism are true, for the conclusion to be true. And the reason is that, when two things are so related to one another, that when one is of necessity the other is, when this other is not, neither will the first be, but when it is, it is not a matter of necessity that the middle is in the position of one, and in none of the other, if the negative be in one of the two terms: but otherwise the syllogism cannot be.

And speech is called false in one manner, when it appears to be conclusive but is not conclusive, which is called a contentious syllogism (φασιστικός συλλογισμός). (Top. vii. 12.)

Contentious speech is the syllogizing from notions that appear to be common notions, but are not; or it is merely apparent syllogizing. (Soph. Blanch. 2.)

And again, so an argument (κριτική) would appear to be productive of doubt. (Top. vi. 5.)

(34.) Induction (ισχυρός) is the progress from the particular to the universal: thus if a pilot who is skilled in the best, and if he does a thing without exception, the person who is skilled in each thing is the best. And induction is the more persuasive and more clear, and more intelligible to sense, and in rogue among the many; but the syllogism has more force, and is more effective against opponents in argument. (Top. i. 12.)

(35.) Induction then and the syllogism from induction, is through one extreme to syllogize with another with the middle term; for example, if B is the middle term of A and C, by means of C to show that A may be predicated of B: for thus we make inductions. — But C must be considered as composed of all things individually: for induction is made through all. (Analyt. Pr. ii. 23.)

(36.) In a manner induction is opposed to syllogism; for the one (syllogism) by means of the middle term proves the first term to be predicated of the third, but the other (induction), by means of the third term, proves the first to be predicated of the middle term. Naturally then the syllogism through the middle term is prior and more familiar; but to make the syllogism through induction is the clearer. (Analyt. Pr. ii. 28.)

(37.) Probable (σίζης) and Sign (ενεποτις) are not the same, but Probable is a proposition conformable to opinion: for what is probable to this particular way or not produced, or to be not to be, this is probable; for example, that men hate the envious, or like those who love. And Sign must be considered to be a proposition demonstrative either necessary or conformable to opinion: for if when any thing is, the thing is, or when any thing has happened, the thing happens before or after, this is a sign of the thing happening or being.

Entitmythen then (σεβήσκες) is a syllogism from probable or signs. (Analyt. Pr. ii. 27.)

(38.) And an example is, when the first is shown to belong (ενεποτις) to the middle through the like. The third. But it must be shown that both the middle and the first are like the like. For example, let A be bad, and B be to take up war against neighbours; and C, the Athenians, taking up war against the Thebans; and D, the Thebans, taking up war against the Phocians. If then we wish to show that to make war on the Thebans is a bad thing, we must assume that to make war on neighbours is bad. And the evidence of this is from the character of the war of the Thebans against the Phocians is bad. Since then to make war on neighbours is bad, and since the war against the Thebans is against neighbours, it is manifest that to war against the Phocians is bad. Again, if B belongs to C and to D (for both C and D are to take up war against neighbours), and that A belongs to D (for the war of the Thebans against the Phocians was not good); but that A belongs to C: and the Thebans is shown through the Phocians.

And in the same manner also if through more like things,
the evidence should exist of the middle belonging to the first.

Accordingly it is manifest that the example is neither as a part to the whole, nor as a whole to a part, but as a part to a part. In fact it belongs to both B and C, and the one is known. And it differs from induction, in as much as induction by means of all the particulars shows that the first belongs to the middle, and does not connect the syllogism with the thing exemplified. The example both cannot itself and does not derive its evidence from all the particulars. (Analyt. Pr. l. 24.)

(30.) Both modes of proof, that by syllogisms and that by induction, teach by means of things known before; the one taking as a basis two things which are subordinate to principles are known through other things, and the other showing the universal through the evidence of the particular. And in the same manner rhetorical arguments persuade; for they (the arguments) are either by means of example, which is induction, or by means of enunciates, which is syllogism. (Analyt. Post. i. 1.)

(40.) Refutation (λεγεται) is a syllogism of contradiction.

(41.) And objection (πράσμα) is a proposition contrary to a proposition. And it differs from the proposition, in as much as it is possible for the objection to be particular, but the proposition either cannot be so at all, or not at least in the universal syllogisms. (Analyt. Pr. l. 26.)

(42.) Since it is the nature of some things through themselves to be known, and of some through other things (for principles (προφητεία) are known as things subordinate to principles are known through other things), when any one attempts to show through itself a thing not known through itself, then the thing to be proved (τὸ δὲ διὰ τοῦτον) the proposition of which the person who attempts to prove it is an objection.

And people appear to assume what is to be proved in five ways. Most manifestly and first, if a person should assume what requires to be proved. And this in itself does not easily escape notice; but in common names (ἐπιστήμη) and in all those things in which the name and the notion (ὁρισμός) have the same meaning, it is more easy to escape detection. And the second way is when a person assumes the universal when it is necessary to prove the particular; for example, if a person attempting to show that of contrary things (ἀληθεία) there is one science, should universally assume that of opposed things (ἀληθεία) there is one science; for be appears to assume with many other things that which it was requisite to prove by itself. The third way is, if any one, when the thing proposed is to show the universal should assume the particular; for example, if he had to prove that of all contrary things there is one science, he should assume that there is one science of some particular contrary things; for such a one also appears to assume separately by itself which it was requisite to prove together with others. Again, if he who should admit them (οἱ δὲ οίκου) by dividing it; for example, if, when it was required to show that the art of medicine concerned both health and sickness, he should assume each separately. Or if any one should assume the universal, which is not the nature of the particularity; for example, that the side (of a square) has no common measure with the diagonal, when it was required to show that the diagonal has no common measure with the side. (Top. viii. 13.)

(43.) The affirmative (demonstration) is prior to the negative, and more easily known, for through the affirmation the negation is known, and the affirmation is prior, as being also is prior to not being. Further, it is nearer to a first principle; for without the positive proof there is no negative proof. (Analyt. Post. i. 25.)

(44.) All persons who form a conclusion through that which is in an errour form a false conclusion, but they show what has to be demonstrated by virtue of an hypothesis, when anything impossible results by the assumption of the contradiction (ἀντιμετώπωσις) (10). (Analyt. Pr. l. 50.)

The contradiction which leads to an impossibility is thus: If it were required to show that A does not belong (ὑποκύπτει) to B, it must be assumed that it does, and that B belongs to C, so that it follows that A belongs to C. But let this (A) be the object of demonstration, and agreed to be true. Then it is not possible for A to belong to B. If then it is granted that B belongs to C, it is impossible for A to belong to B. And since the affirmative (ἀπειροπώσις) demonstration is better than the negative (ἀναπειροπώσις) demonstration which leads to impossibility. (Analyt. Post. i. 20.)

(45.) The object of science and science differ from the object of opinion and opinion, in as much as science is universal and is of necessity, and the necessary cannot be otherwise, but opinion is unsettled (Analyt. Post. i. 38.)

(46.) Induction is not possible when there is no sensible perception; for sensible perception belongs to the particular. Nor yet through sense nor through perception is it possible to attain science. And therefore, the object of science is not being in the same thing as being of a certain quality, and not to any definite thing, nevertheless it is necessary to have some one definite thing as the sensuous object, and the where and the when.

But what is universal and imperceptible, and that which is the sensuous perception of, for it is neither any particular thing nor now; for, if it were, it would not be universal; for we affirm that the always and the everywhere are universal. Wherefore also the object of induction is not to perceive the light of the sun), we should not know the cause of the eclipse, for we should perceive that it is eclipsed now, but we should not know why at all, for there would be no sensible perception of the universal. (Analyt. Post. i. 18, 31.)

(47.) And I call universal whatever belongs to all both of itself and in itself. It is manifest then that whatever is universal of necessity belongs to the things, and the 'in itself' and 'in itself' are the same; for example, of itself a point belongs to a line insuch as it is a line; and to a triangle, insuch as it is a triangle. And to the right angle insuch as it is an angle; and for itself the triangle (as to angles) is equal to two right angles. And the universal then, when it can be demonstrated of any individual (of the class) and of no class prior thereto. (Analyt. Post. i. 29.)

(48.) To what thing anything of itself belongs, that very thing is its own cause (αἴρετος); and the universal is first, therefore the universal is the cause. (Analyt. Post. i. 24.)

(49.) Universally, of all things it is impossible for there to be demonstration; for it would proceed indefinitely, so that there would be no demonstration at all. (Metaph. iv. 4.) And it is not possible for the thought to go through the infinite. (Analyt. Post. i. 29.)

(50.) And those things are true and first which not through other things, but through themselves receive assent; for it is not necessary in scientific first principles for the 'wherefore' to be inquired after, but each of the principles must itself of itself receive assent. (Top. i. 1.) And in two ways it is necessary first to know: for as to some things it is necessary first to admit that they are; but as to others it is necessary to understand what the thing specified. If we believe both against both; for example, in the proposition that either to affirm or deny every thing is true, we must assume the 'is'; and in the triangle, that it signifies this particular thing; and in the proposition that there is no common measure with the side.

(51.) But we assert that all science is not demonstrative, but that of the immediate (αὑριστοῦ) is incapable of demonstration. And that nothing of necessity is known, in that it is necessary to understand the prior and those things from which the demonstration comes, and the immediate at any time enter into the demonstration, it is a matter of necessity that the immediate are not capable of demonstration. And this we so affirm, and that there is not only science, but also some first principle (ἀρχή) of science by which we know the things (ὅσα). It is necessary not only to know first the first things, either all or some, but also to know them more; for always that through which each thing is, is more (in a higher degree); for example, that through which we love, is more love. So that if we know by the first things and believe, those things also we know and believe more, since by them we know also the things which come after. (Analyt. Post. i. 13, 2.)

(52.) And an immediate proposition (συνάρκτικον) is a beginning (ἀρχή) of demonstration, and an immediate proposition is that to which there is no prior proposition. (Analyt. Post. i. 2.)

(53.) And an immediate syllogistic beginning I call that the Thesis which need not be demonstrated, and which it is not necessary that he who is going to learn anything should possess; but what he who is going to learn anything must necessarily possess, is an axion (ἀξιώμα). (Analyt. Post. i. 9.)

(54.) The first things will be definitions (ὑπόθεσις) incapable of demonstration. For definition is of what the thing is and of essence; but all demonstrations appear to go by hypothesis and to aware what a thing is, for example, (Top. viii. 13.)

* See Cæs. v. 3, definition of Διάταξις and Ἀπεριτωπώσις.
the same thing as to be related to something in some manner, and this is impossible without the one to know the other; wherefore it is necessary in the notion (άναθος) of the one that the other also be included.

Another way is, if a man uses the very thing which is defined, as in the above case, he escapes notice, when he has used the name itself of the thing defined; for example, if he defined the sun to be a star which appears in the day-time; for he who employs the word day employs the word sun. And it is requisite in order that such errors may be detected to exchange the name (άναθος) for the notion (full speech, ἄναθος), for example, that day is the passage of the sun above the earth: for it is manifest that he who has spoken of the passage of the sun has not spoken of the sun. Again, it may be supposed that he who has employed the word day has employed the word sun. A third way is, that if that which is opposed in division is defined by that which is opposed in division, for example that odd is greater than even by a unit. For things of the same genus opposed in division exist by nature, and odd and even are opposed in division: for both are differences of number. (Zop. vi. 4.)

To know what a thing is, is the same as to know why it is. What is an eclipse? Privation of light from the moon through the earth intercepting the light. What causes an eclipse? Or why is the moon eclipsed? Because the moon is between the sun and the earth, but they have all in common, and in the other things in like manner, we must consider again if there is anything in common in these things which have been taken, until you come to one notion (άναθος): for this will be a definition of the thing. But if a man does not come to one notion, but to two or more, it is manifest that what is sought cannot be one, but more than one. For example, if we should inquire what magnanimity is, we must consider in the case of some magnanimous persons whom we know, what one thing they all have by which they are such. For example, if Achilles is magnanimous, or Achilles, Ajax, and Agamemnon, we shall find that they have all in common, the absence of insult; for the first was war, and the second was enraged, and the third killed himself.

Again in the case of others, such as Lycurgus or Socrates; if difference in prosperity and adversity are the things that they have in common, these two things I take and consider what same things are contained in the absence of feeling (μισεία) as to fortune, and non-endurance of insult. If then these things, in the same case, there must be two species (τίτων) of magnanimity. (Analyt. Post. ii. 13.)

(57.) Of the things indeed which are in the definition each will extend further, but all will not extend further. For of necessity there must be this essence (ζωή) of the thing: for example, there is number in every Three (τρία), odd (πράπτω), and the prime in both ways, both so as not to be measured by any number and not to be composed of numbers. This then is Three, number odd, and prime, and in this manner: for of each of these things some are in all odd numbers also, but the last is in Two also, and all are in none. (Analyt. Post. ii. 13.)

(58.) And it is necessary, when a person is labouring at any whole thing, to divide the genus (γένος) into things indistinguishable in species, the first: for example, to divide number into the odd (πράπτω) and even (κόης) species. All genus is divided by differences which are opposed to one another in division, as a living animal by the difference of quadruped and bird and fish. (Zop. vi. 6.)

(59.) If you should fall under accident, if they be things opposed in which there is no middle, is not an assumption, for it is necessary that everything should be in one of them, if there shall be a difference (διαφορά) in it (the genus). (Analyt. Post. ii. 13.)

It is requisite moreover to divide by privation (απώνοια), and those who cut into two parts divide by privation. And there is no difference in privation, so far as it is privation, for it is impossible that there should be species of a thing which does not exist; for example, of animals without feet or animals without wings, as there is in the case of winged animals and quadrupeds. (De Partib. Animal. i. 3.)

(60.) Definition consists of genus and differences. (Zop. i. 6.)

It is requisite that he who defines well define through genus and differences, and those belong to those things which are given with each and prior to species, which does not exist; for example, of animals without feet or animals without wings, as there is in the case of winged animals and quadrupeds. (De Partib. Animal. i. 3.)

(61.) We seek the cause after we know that a thing is; but sometimes they are manifest at the same time also; but it is not possible to know the cause before we know that the thing exists. (Analyt. Post. ii. 2.) For it is impossible to know what a thing is when we are in ignorance whether it exists or not.

And both the notion or expression (άναθος) appears to have evidence to phenomena, and phenomena to the notion. (De Coot. i. 8.)

(62.) The cause is the middle (μέσον), and in all things this is sought. (Analyt. Post. ii. 2.)

(63.) Not only that a thing is, is oftentimes the definition (άναθος), and not the middle (μέσον), and not the reason, for example, what is quadrature? Is it a regular equilateral square being equal to a figure of unequal sides? And such a definition is an expression of the conclusion. But the definition which says that square is a figure of a middle, states the cause of the thing. (De Coot. ii. 2.)

(64.) And it appears that not only that what a thing is, is useful towards knowing the cause of the accidents of essences (τὰ τοῦ ἐγχείρημα τῶν ἀνείσερων), as well as to their being, and the straight line is and what a curved line is, or what a plane and a plane arc, is useful towards seeing how many right angles the angles of a triangle are equal to, but conversely also the defining the thing which is greatest, it is evident that the thing which is, and what is the cause of the thing is: for when we are able by the appearance (ἐξουσία) to give an account of the accidents of all or of the greater part, then concerning the essence also we shall be able best to speak: for of all demonstration what a thing is (εἰπώ τινα τοῦ), is the beginning. So that in all definitions in which it does not happen that we can recognise the accidents, and cannot even form a conjecture of them easily, it is manifest that they are all enunciated dialectically (μισείας) and empty (μετρεῖον). (De Animal. i. 1, § 8.)

(65.) And of some things some other thing is the cause, and of other things not.

According to him who manifest that of those also which belong to the class of what a thing is, some are immediate (ἀκόλολ) and first principles (στροφὴς), which we must assume (ἐπιλεκτικόν) both to be, and we must assume what they are, or in some other way the clear, as it were the other, which common to both what unity is and that it is he assumes. But as to those things which have a middle (μέσον), and of which something else is the cause of the essence, we can, as we have said, show by the demonstration of the double what things are. And if that which takes for granted either of the parts of the enunciation, for example, that a thing is, or is not, is Hypothesis (ἐπίθεσις); but the proposition without this is Definition: for the definiti-
tion is proposition (δέους); for the arithmetician lays down (πας, places, ἑπέρα) that the unit is indivisible, as far as quantities (δύος) of which it is not hyphenable: for when the unit is and that there is a unit is not the same thing. (Analyt. Post. i. 2.)

(67) All demonstrative science is about three things, two of which are no accidents (ἀφάντα) of which it is not hyphenable: for when the unit is and that there is a unit is not the same thing. (Analyt. Post. i. 10.)

(68) It is clear that it is not possible to demonstrate the peculiar first principles of each thing: for those first principles (αρχές) and that which is indivisible (διαφανές) of those is that which is supreme over all. For he knows more who knows from the higher causes: for he knows from the prior when he knows from causes which depend not on other causes. So that if he knows more and most, that science also will be both more and most. (Analyt. Post. i. 9.)

(69) Accordingly it is impossible to have science from demonstration, if a man does not know the first principles which admit of no middle (κατάλληλα) for those he has before been said. But as to the knowledge of things which want a middle, a man may be in doubt. All animals have an innate discriminating faculty, which men call perception (αἴσθησις). And as they have sense-organs, so they have distinguishing sense-organs (μυς) of the thing perceived (ὁσανύμος); and in others there is not. In those animals, then, in which it is not, there is neither wholly, or with respect to things of which there is no perception. And those things they do not perceive: but in those animals in which there is, there is the faculty of having the perception in the mind, though they do not then perceive. And many animals being such, there results a difference among them, so that some have reason owing to the permanence of such things, and some have not. Accordingly from perception comes memory (μνήμη), as we call it, and from the frequent remembrance of the same thing comes experience (πραξια), as we call it, which is quite another experience. And from experience, or from a whole thing remaining tranquil in the mind as one thing apart from the many, whatever thing in all these things is as one and the same thing, is the beginning of art and of science; if about production (ἐργασία), of art; if about that which is or being (εἶναι), of science. Neither indeed do the faculties (ἐφευρέω) exist in the mind separate, nor do they proceed from other faculties which are more intelligent, but they proceed from perception; as in battle when a flight has taken place, when one stops, another stops, and then another, until order is restored, and the mind exists in such a manner as to have the faculty of knowing and of perceiving (γνωρίζω) what are not different stands, it first of all is the mind as universal (for the mind perceives the individual, but the perception belongs to the universal, for example, it belongs to mankind, but not to this (ὁμοιοί) and again to those until the individual and the universal have abided: for example, such or such an animal abides, until animal generally abides; and this in like manner. It is manifest then that it is necessary for us to know the first things by induction; for perception also in this manner produces the universal in the mind.

And since of the faculties that concern the understanding (επιστήμη), by which we learn the truth, some are always true, and some admit of falsehood, as opinion and reasoning (λόγος-μετάφρασις); and since science and intellect (ἐνεργεία καὶ γένος) are always true, and there is no other kind of science more exact than intellect, and since the first principles are clearer than the demonstrations, and since all science is together with reason (λόγος),* there can be no science of the first principles: and since nothing can be truer than science except intellect, intellect must be intellect of first principles: and this appears both from considering these things, and that the beginning of demonstration is not demonstration, that neither is the end of the beginning of science. If then we have no kind of truth with an external object (διά βιβλίων) must be the beginning of science. (Analyt. Post. ii. 19.)

Ogres, DRESSING, &C. OF. (Mining, P. C., pp. 286, 287; Cocker, P. C., p. 592; Tim. Manufacture of, P. C., p. 471.)

* The word λόγος is rendered 'ravis' by the Latin translation. 'Readefully translates the passage thus: 'kede wamabetai akor nici an eindメニュー verkieslet le.' Perhaps in some may be understood as in No. 2. 'Any' should be rendered as 'λόγος as (Echolocating, Echolocating) to the ear.'
flowers, the peduncles are longer than the linear lanceolate bracts; lanceolate, simple, filamentous leaves. The flowers are white, with a broad green longitudinal band externally. It is found in meadows and pastures in Great Britain, and is the foundering of Tribus Orobanchaceae. Hist. Plant. 7. 7. 10; 11. 12. 13. 14. 15.

Orobacaria. Fraas, Orobacaria. It is distinguished by the brown, tubular, terminal, upper lip, which is often much longer; the middle of the tube compressed on the back; the throat is slightly inflamed externally; the glandular lobes of the lip oblong, with reflexed margins, lower lip bony within, nature of the other lip very various. It is natural to Europe, in Austria, in Germany, and the south of France. It has been rarely found in Great Britain in the fields of Hampshire and Norfolk, and in Ireland. The flowers have a blue blossom. It is parasitic upon Broom, Rape, Lathyrus, and crops.

P. ramosa has a calyx of 4 sepals, tubular, with triangular ovate acuminate teeth, the anthers glabrous, the stem branched. This plant is a native of Europe, and has been found in Great Britain in Norfolk and Suffolk, where it grows on the roots of hemp, and the Gallopois Tintat. There are several other species of Phelippe, which were formerly described as belonging to the genus Orobacaria. All the plants belonging to Orobacarchaeus, have the habits and general character of Orobacineae. The genus belonging to this order are distinguished as follows—

Tribe I. Orobacineae. Parasitical leafless herbs.

2. Phelippea. Calyx tubular, bibracteate, 4-6-toothed or 4-5-cleft.
3. Aeschynomene. Calyx bracteate, 6-cleft, sub-bibracteate.
5. Camphora. Calyx ventricose, 5-parted, bibracteate, corolla incurved; upper lip entire, lower one bident.
7. Lathyrus. Calyx bibracteate, campylopodi, 4-cleft.
9. Alchemilla. Calyx bilobate, bracteate? upper 2-cleft, lower one bisected, the capsule acuminate, pointed.
10. Aegopinon. Calyx spathaceous, capitate many-celled.
11. Amblyanthus. Calyx campylotoid, 4-cleft, both lips of corolla entire.

Tribe II. Orobacaridae. Terrestrial leafy plants.

13. Tussia. Calyx 5-toothed, bracteate? (?) corolla ringent, tubular; capsule 1-seeded by abortion (?)

(Don, Gardener's Dictionary; Lindley, Vegetable Kingdom; Babington, Manual of British Botany.)

OROBACUS. [Orobacineae.]

ORRIS ROOT. [Orobacineae.]

ORROVA. [Orobacineae.]

OSMUNDA, a genus of plants belonging to the natural order Ferns; to the sub-order Osmundaceae. It has been described as belonging to a tribe. The fronds of the flowering Fern, has bipinnate fronds, pinnules oblong, nearly entire, dilated, and slightly auricled at the base; the clusters panicked, terminal. This fern is a native of Great Britain in boggy places, and often attains a height of from 1 to 8 feet. It is very common in many parts of England, and especially on the lake of Killarney in Ireland. It is common throughout Europe, and a plant of the same name is found in the United States.

(Babington, Manual of British Botany; Newman, British Ferns.)

OSSIFEROUS BRECCIA, OSSIFEROUS CAVERNS. The existence of large fissures and caverns in rocks is a fact known to miners and quarrymen in all parts of the world; that these cavities are frequently filled with stratigraphical strata and earthy accumulations, and sometimes with the bones of animals, is another fact on which modern geologists have based a long train of ingenious inferences. Fully to examine these facts and inferences would be to discuss one of the most comprehensive and unsettled problems of geology; it is possible however to present in a small compass the leading considerations which belong to the subject. Great caverns and vast caverns, sometimes confined to limestone rocks, are yet by far most frequent occurrence in these deposits. They are not common in all limestones, but have certain determinate relations to their mass and the positions which they occupy. It is peculiarly in thick masses of limestone, (whether magnesian or purely calcareous)
that we find great caverns in England, Ireland, France, Belgium, North Germany, the Tyrol, Carinthia, Italy, Greece, South Africa, India, Asia, North and South America. It is
sometimes observed that great caverns abound in limestone
rocks, not so much at near to points and lines where
the ordihinary position of the strata is violently disturbed
by earthquakes, or through the action of water on the
numerous caverns of Derbyshire and Yorkshire, and the
Mendip Hills, are situated in or near to situations of
violently disrupted strata, and by accumulating observations
of this nature we gradually reach the conclusion of the
dependence of the chasms in the rock on the fractures
which have broken it.

But there are few caverns or great fissures all whose
formation can be explained. The distinction has not so
often produced the caverns as the conditions necessary for
their production. On the contrary, in very many cases we
perceive, even in caverns now dry, forms of internal surface
which mark the decomposing influences of air and moisture
and the erosive power of running water. Through many of
these water now runs, through more of them it formerly ran,
conducted into these subterraneous channels by the fractured
condition of the strata. The great caverns of the Peak at
Castleton and Buxton may be quoted as examples. Other
caverns occur, nearly or entirely exempt from the direct in-
fluence of water passing through them. Such a case occurs at
Kirkdale in Yorkshire, where the fissures have cut through
an even floor and roof, and is connected, not with faults or
axes of movement, but with great joints in the limestone.
The cave is a great tunnel, traversed by water coming down
from the hillside. Water dropping through, or passing through the
limestone rocks dissolves (by the almost constant car-
bonic impregnation which it derived from the atmosphere and
decomposing vegetation) its calcareous channels, and trans-
ports away, to the surface of the ground, the materials of
petrifying springs, the tufaceous mounds of Mallock, and the
traversing of southern Europe. In certain classes of lime-
stone rocks there is reason to conjecture that the caverns have
not been occasioned by violent fractures, nor yet by the influ-
ence of joints, but that they are a part of the original
structure of a coral reef (in which cavities were left by the
polyplexe builders), or have been generated by those chemical
processes which we have as yet imperfectly traced and classed
as metamorphic effects. This may be the case in certain
magnesiferous (dolomitic) limestones in Derbyshire, Fran-
conia, &c.

In regard to the filling of these caverns, we are just on
a great majority of instances, appeal to the action of water—
an inverse action, new circumstances causing water to deposit
where once it evaporated: an expedition into the caverns, by
fresh new accidents. Stalactetical depositions and many varieties of
spray accumulations, which are now happening in caverns
and fissures, exemplify the former case, and as an instance of
the latter, we have the famous 'sandstone caves' of the north-
yorkshire coast. Here the chalk is cavernous; the caverns,
connected above with small fissures reaching to a mass of
diluvial clay, pebbles, &c., are continually enlarged by the
water accumulating there, which has eroded away the over-
lying sandstone. Water running in, and the diluvial masses from above pour down
into the cave, but are soon removed by the agitation of the tide.

Another case of familiar occurrence in the mining
districts of the north of England, where limestone, more or
less cavernous and fissured, is covered by shales or argilla-
ceous toadstools. Near the edge of these argillaceous beds,
many rather regular pits ('cavern holes') occur, through
which the surface drainage reaches the limestone, and carries
into its cavities some of the materials which are disposed in
its course.

The geologist, who takes into consideration the possible
origin of caverns in limestone from original hollows, the in-
fluence of joint fissures, and the effect of violent displac-
ements; and considers further the various degrees and circum-
stances of their communication to the surface, the various
action of water within them, their level in relation to that
of the sea, and the nature of the strata or other matter
superincum-
benent on the limestone, will be at no loss to comprehend
how the bivalve mollusc is complicated by the influence of the sub-
terraneous waters; the muddy and earthy contents of subterraneous caverns. These contents
have in some cases fallen in, so as to constitute confused heaps
or masses of breccia: in other cases they have been drifted
by the water up the fissures, and deposited into the caverns;
and, in addition, certain matters have been dissolved, and deposited in
crystallized and stal-'gnmitic forms.

The occurrence of bones in these breccias, sediments, and
stalagmitic instrusions is sometimes to be explained by sup-
posing them to have been derived, by flowing or being
or to have been drifted with sediments by water; but in a
considerable proportion of the cases which have been examined
there is no avoiding the conclusion that animals retired
by the water, and those bones have been left in these
caverns, and there have left their bones. This con-
clusion, established by the sagacity of Buckland for the hyena
caves of Kirkdale and Torquay, applies to the numerous bear
and hyena caverns of the Iberian peninsula, and to
some caves in Brazil and Virginia. It is a conclusion of the
highest importance in geology and zoology. It assures us
of the widest occurrence, in various branches of life, of
caves where the animal species of one or two genera can be
observed, as in the Iberian and Brazilian caves, and which
are frequent in the northern zones of the world, and of
such startling magnitude as to have suggested hypotheses of
diluvial catastrophes, and of glacial periods, to geologists; while zoologists may perhaps
regard it as a great example of the law of limited duration
and successive predominance, to which, judging from the
whole course of palaeontological discovery, all the races of
the animal creation are made subject. The reader may consult
for the facts and inferences thus briefly noticed, Cuvier,
Oeuvres, Paris: Buckland, Reliquiae Diluvii, Meyer,
Palaeologia; Owen, On British Fossil Mammalia, in Trans-
plications of the British Association; and a variety of memoirs
by different authors in the Transactions and Proceedings
of the Geological Society of London.

OSTRACION. [ECL.EDWHEU]MANN.

OTTMER, KARL THEODOR, an architect to whom
Brunswick is indebted for what ranks almost among the
largest, and certainly among the most elegant palaces in all
Europe, was born in that city, January 19th, 1800. He was
the son of a physician, who intended the youth to pursue
a professional career; but his father's death leaving him free to follow his
own inclination, he made choice of architecture as his future
destination, and certainly had no cause to repent of doing so,
being eminently successful in all the stages of his career by opportunities that fall to the lot of few. While he
was completing his studies in his profession, at Berlin, in 1822;
he was employed to erect the new theatre there, called the Kurf&uuml;ster-Theater. This building was
burned by a drunken man in July 1823, and opened in the August of the following year.
This decided success on the part of one so young,—it
being in fact his coup d'essai,—brought Ottmer forward at once:
he should, however, be mentioned that, although it was not
known at the time, his designs were corrected by Schinkel.

SCHINKEL, K. C. S.

In his next work of note, the 'Sing academy' at Berlin (erected 1826-7), his design obtained
preference of that of Schinkel, although the latter was in very
superior taste, and indeed, one of the happiest ideas of the
great master,' as may be seen by the published drawings of
its in his 'Entwurf,' Planning as all this was, it was not
without its disadvantages, as by immediately and too completely in matters of mere business, it hindered
that calm application to study which is so important to an
artist at the outset. There was besides a certain degree
of his being spilt by the exaggerated praises bestowed on his
early efforts,—praises which, it has been suspected, proceeded
partly from a desire to lessen the reputation and keep down
the prices of his works. These were but minor inconveniences;
and after first studying a short time in Paris, he visited Italy,
where he remained nearly two years (1827-5); and where he was so far inspired as to con-
ceive the project of erecting one of the ancient temples and
the Parthenon, which should supersede every known edifice of the kind in extent and
magnificence.
He was recalled to Germany by an invitation from Dresden, where he was to build new pavilions, and he proposed designs accordingly; but the scheme was dropped for several years, and then Semper was the architect employed on the noble structure since erected there. The designs produced a great sensation, especially in Dresden, for him while he was at Dresden, a commission from the Duke of Saxo-Meiningen to make others for a theatre and casino for him, and the buildings were forthwith commenced. On his return to Brunswick, in 1830, the first part of his *Architektonischen Mittheilungen,* containing plans, &c. of his Theatre at Berlin. At that time his professional occupation consisted of little more than his official duties as Hofbaumeister, nor a very great deal of ever belting on any work of importance, when during a popular tumult which took place in September, 1830, the palace at Brunswick was set fire to and destroyed. He was thereupon directed by the new Duke, Wilhelm (the successor of his brother Karl, who was expelled by the revolution), to make designs for rebuilding the palace; and the edifice was begun the following year, and prosecuted with such activity as to be ready for habitation in 1837. The principal mass is 400 feet in extent, by upwards of 200 in depth, and 80 high, and in the centre considerably loftier, though the design has not yet been fully carried out, the open colonnades intended to form a place before the principal elevation which is being erected. Still, in should nothing further be ever done, this palace is a most stately and elegant pile as it is; and even now it has been objected to it that it is too extravagant and costly a scheme for the labors most prodigious, and besides that he was obliged to superintend every department of the works personally, from first to last, he designed all the numerous details both of the exterior and interior, which display considerable inventive powers as well as refined taste. The principal elevation of the exterior—extending altogether two thousand feet in length—is entirely of cast-iron, and much equally excellent and novel combinations in its details in other parts. The interior is further distinguished by many striking pieces—the lower entrance vestibule, a Grecian Doric hall 150 feet in length; the parade staircase; the upper vestibule, a rotunda seventy feet in diameter, and sixty high; gallery; theatre; concert room; banquetting room, &c.

Besides the palace, Otten erected at Brunswick several other structures, both public and private, all of them, more or less, of architectural note: viz. the Theater-Intendanz, the Infantry Barracks, in the Florentino style, with a facade of 350 feet; the Iron Bridge, the Villa Bulow, New Richmond, the Schmidsche-Haun, the Interim Railway-station, &c. &c. He also made a design for Cavalry Barracks at Brunswick, in similar style to those for the infantry; which design was published in Ronsberg's *Zeitschrift für praktische Baukunst,* 1838. But that design, which he has since withdrawn, will perhaps remain unedited. Naturally of a delicately constituted, Otten sank under the haras of business and the multiplicity of his tasks in the prime of life, August 22nd, 1843; but he had lived as a man of the century, hardly would he have had such another opportunity as that afforded him by the Palace of Brunswick.

**OVAL, or as the name imports, egg-shaped, is the name given originally to such a form as the section of an egg presents, round, but not circular. In mathematics it has received some extension of meaning. Any curve, or isolated branch of a curve, which returns into itself, would be called an oval: perhaps even a figure of eight would receive the name. The curve having for its equation**

\[ y = \frac{1}{x} (x^2 - a) \]  

\[ (x^2 - b) \]  

\[ (a \text{ and } b \text{ being positive; and } a \text{ less than } b) \]  

\[ \text{has an oval extending from } x = a \text{ to } x = b \text{, but there is no curve whatever from } x = a \text{ to } x = b, \text{ or from } x = b \text{ to } x = 0. \]  

\[ \text{If } a \text{ be small, the dimensions of the oval are small: and when } a = 0 \text{ the equation becomes} \]

\[ y = \frac{1}{x} \sqrt{x^2 - b^2} \]  

\[ \text{in which the oval has become a point (the origin), and is a conjugate point (Curv. P. C.):} \]

\[ \text{of which it is an asymptote, but which is on no continuous branch.} \]

Some conjugate points have none but imaginary values of \( y = \sqrt{x^2 - b^2} \) and \( y = -\sqrt{x^2 - b^2} \), which is a conjugate point at the origin, and \( y = \pm \sqrt{x^2 - b^2} \) is then imaginary: but when \( x = \sqrt{x^2 - b^2} \) there is a conjugate point at the origin, and \( y = \sqrt{x^2 - b^2} \) is 0. The meaning seems to be (as far as we can judge from a few instances) that such a point is a kind of cusp, which preserve a finite ratio to one another, so that its tangents fall in all directions, the ultimate value of \( dy/dx \) is imaginary. But when one of the axes diminishes without limit, the other tends to the finite limits. Thus when \( x = 0 \), the ends of that axis, the tangents tend to assume one direction, there is an ultimate value of \( dy/dx \) which defines that direction. If our surmise be correct, a double or triple value of \( dy/dx \) at one of the points to which our attention is directed, a star-shaped oval, or of one which tends to assume that form as it diminishes. But this, with other points relating to the singular values of algebraic functions, has yet to be fully conformed.
OZON

attention of Lord Clarendon. This statesman, who was anxious to reconcile the most moderate of the non-conformist party (Hyon, P. C.) offered Owen immediate prefiguration if he would continue his labours, and was thus encouraged, though respectfully declined. He then formed a congregation, among which he assiduously laboured, and in conjunction with Baxter, Bates, and other leading men of his persuasion, instead of the 10th Weekley Lecture on 16th Dec. 1667, he contracted a second marriage, by which he was enabled to live in comparative affluence on an estate at Ealing, in Middlesex, where he died on the 24th of August, 1689. The biographic species described are very widely distributed over the globe. The hardy species require no care. If the roots are planted in a shady border, they will grow and multiply. The greenhouse kinds are mostly bulbous from the Cape of Good Hope. A mixture of the seeds is in a great measure reflected in his works, which, though strongly tinged by the peculiarities of the Calvinistic system, are remarkable for their devotional spirit and are calculated to encourage practical piety. He certainly contributed to that section of his party whom Lord Clarendon designates as 'the more learned and rational.' (Clarendon 'History of the Rebellion,' vol. v. p. 515, see Warburton's note.) His works are very numerous, the best known of which are not already alluded to may be mentioned: 1, 'Exposition of the Epistle to the Hebrews'; 2, 'A Discourse on the Word of the Lord,' 1665; 3, 'A Sermon on the Birth of the Babe in a Shepherd's Stable, to the Answer to T. Biddle,' 1665; 4, 'εὐχαριστία τῆς ζωῆς,' avid de Nat. Ortu, Progressu et Studio Vere Theologic, 1661; 5, 'An Exposition of oxv Psalm, 1660; 6, 'On the Doctrine of the Trinity,' 1661; 7, 'A Letter to Daniel Fry, Alias Gnomon, 1665; 8, A large collection of Sermons and Tracts. His last production was entitled 'Meditations and Discourses on the Glory of Christ,' which it was stated was sent to the press the day he died.

(Don, Gardener's Dictionary: Babington, Manual of British Botany; Lindley, Flora Medic.)

OXYRIA, a genus of plants belonging to the natural order Polygoneae. It has a 4-parted number, and in the 3 interior segments larger; 6 stamens; 2 stigmas; a 1-seeded nut, compressed, with a membranous wing, larger than the persistent segments of the seed. O. raniformis, Mountain-Sorrel, is the only species. It is found on the highest mountains of Great Britain, and is an inhabitant of Europe. It is the O. digynia of many botanists.

OZONE (from the Greek ὄξιν, to smell) is the name given by Professor Schönbein of Basel to an odor evolved during the progress of certain electro-chemical decompositions. It is also produced by common electric sparks, and by the working of an ordinary electrical machine in the air. This odor attracted no particular notice until M. Schönbein called the attention of the British Association to it in 1840; since which time it has undergone much examination, and various theories have been propounded as to its nature and composition.

Ozone is evolved at the anode, or positive pole of a galvanic battery, at the same time with oxygen, during the electrolyzation of any of the following bodies, viz. water, dilute sulphuric acid, solutions of phosphoric and nitric acids, potassa, and many oxides. Ozone yields it in the greatest quantity. It may also be obtained from atmospheric air, oxygen, nitrogen, hydrogen, carbonic acid, and nitrous oxide, by passing the electric current through the least common multiple of the same, and frequently making and breaking contact. Under the influence of heat ozone disappears, and it cannot be obtained from heated solutions, or solutions of hydracids, chlorides, and sulphates. The purity of the gas, and the considerable quantities, prevents its evolution from solutions otherwise yielding it abundantly. It may be developed by electrolysing a solution of muriate of soda with platinum electrodes, by placing the gas collected at the anode over ammonium and water to absorb the chlorine. Ozone can be preserved for a length of time with the oxygen collected in it with well closed bottles. It possesses the property of bleaching linen-paper and paper coloured with indigo or a solution of that substance. It is readily absorbed by mercury and the oxidizable metals, forming oxides with them; and when the solutions employed are heated its affinity for metals is so great that it combines with platinum and gold. Water absorbs it. The inspiration of ozone is very injurious, and the effects similar to those resulting from chlorine and bromine. A mouse is killed with it in five minutes, and M. Schönbein was immediately affected by breathing an atmosphere charged with it.

The electrodes employed in these experiments have a great influence in respect to the evolution of ozone. With water or distilled water and platinum, or gold, for when the more oxidizable metals are used it enters immediately into combination with them. It can be obtained from air or the gases above enumerated when there is a mixture of copper, iron, silver, or platinum, and zinc negative, but not when these arrangements are reversed, or both electrodes are of zinc. With zinc, when either positive or negative, a peculiar scent is produced in nitrogen and hydrogen. On electrolyzing a solution of sulphuric acids the following results

VOL. II. – 3 E
are obtained— with platinum electrodes the odour is very powerful; but it is not produced when copper, zinc, or iron electrodes are employed. With boxwood charcoal the gas given off from the positive pole has no smell; but when absorbed by lime-water it turns milky, proving the gas to be carbonic acid. With gas charcoal, sulphuric acid is evolved at the negative pole and carbonic acid at the positive; but no odour of oxygen is produced. With a solution of muriate of soda the odour is not perceptible until the gas obtained from platinum electrodes at the positive pole is placed over ammonia and water to absorb the chlorine. The residual gas emits the peculiar odour.

There exists much variance in the experimental results with this new substance; and not less in the opinions concerning its nature. Professor Schönbein considers it to be a trioxide or peroxide of hydrogen. Marignac controverts M. Schönbein’s conclusion, that it is to be derived from the decomposition of nitrogen, as he obtained it from water free from this latter gas. Mr. Williamson would prove that it is a compound, and that hydrogen is one of its elements, he having obtained it from a salt of copper, and passing the oxygen with the ozone over metallic copper which had been reduced by carbonic oxide gas, a sensible formation of water resulted. His view of the subject is, that ozone is a higher oxide of hydrogen than water, although not the peroxide of hydrogen of Thénard, which is not volatile like ozone, but inodorous and fixed. Mr. Gann’s opinion is, that I am inclined to think that this peculiar odour may be emitted from all metallic bodies in such a manner as to prevent oxidation or combination with other bodies; and that all metals have the power of emitting it, when put into a peculiar electrical state, that is, when the metals are in a state of transition previous to oxidation or combination; and Mr. Lake, who claims to have demonstrated that the electric fluid is a substance, to which he has given the name of pyrogen, [Prazoox, P. C. S.], considers that it is a compound of this substance with oxygen, that is, an oxide of pyrogen. He says, ‘It would seem indeed the necessary inference of Mr. Gann’s experiments (the evolution of ozone from oxygen and the other gases) that oxygen enters into the composition of nitrogen and hydrogen, for ozone is developed, except in these two instances, from oxygen and its compounds, by the combination of oxygen with pyrogen, and hence it would follow that nitrogen and hydrogen contain oxygen.

The inquiry concerning the substance is of great importance to chemical science, as it involves the question of the nature of oxygen, hydrogen, and nitrogen, from each of which it can be obtained. It is agreed by all that oxygen is one of the elements of ozone. If, therefore, hydrogen is the other, it is evident that oxygen is the primary element of which hydrogen enters; that oxygen is an element of hydrogen; and that both oxygen and hydrogen are elements of nitrogen, since ozone can be evolved from each of these gases: and it is to be remarked that this last circumstance agrees with Mr. G. J. Knox’s discovery, that nitrogen is a compound of hydrogen and carbon. This also overthrows M. Marignac’s opinion, that it cannot be obtained by the decomposition of nitrogen, and confirms M. Schönbein’s to the contrary effect.

Mr. Gann’s opinion, in substance and as far as it goes, coincides with Mr. Lake’s, for he considers oxygen to accrete between the oxidation or combination of the metals with the substances exhibited to them and the time when chemical action commences. According to the views of the latter, ozone must be present and of paramount importance in the processes of acclification and oxidation, for he shows that both oxygen and the electric fluid (which he considers the elements of ozone to be) are required to form an acid [Prazox, P. C. S.], and of course an oxide. If this view be correct it accounts for the disappearance of ozone where the more oxidizable metals are exhibited to it, and also for the formation of carbonic acid when acid solutions are electrified with carbon as the positive electrode.

Some singular phenomena connected with ozone were observed by Professor Schönbein, strongly indicative of its electric origin, if not of its electric composition. When perfectly clean and dry plates of gold or platinum are immersed in oxygen containing ozone, they acquire a negatively electric state of polarity. Silver and copper also become thus electric, but in a less degree than gold or platinum. The plates thus polarized retain their electric powers in air for a considerable time, but rapidly lose them when plunged into hydrogen gas, in which, if retained a sufficient time, they acquire an opposite state, being thus positively polarized.

When a perfectly clean and dry plate of gold or platinum is exposed to an electric brush it becomes positively polarized, the degree of polarity depending on the nature of the point and the time the plate is exposed to the brush lasting from it. This power may be attributed, according to the last of the above theories, to the formation of ozone by the combination of the electric fluid of the brush with the oxygen of the air.

If the point from which the electric brush is issuing be moistened with water, the electricity still continues to be given off, but the power of polarizing the plates is lost, which effect is no doubt produced by the water absorbing the ozone. Heat, which destroys, or exposes to hydrogen, which inverts, the electricity of a plate that has been polarized by exposure to oxygen containing ozone, exerts a precisely similar action on plates polarized by the electric brush.

According to Professor Schönbein, nitrogen is a combination analogous to hydrochloric acid, and is composed of ozone and hydrogen.
PACCIAROTTO, JA'COPO, one of the most distinguished of the old Sieneese painters, was born at Siena in the latter part of the fifteenth century; but though he belongs chronologically to the painters of the sixteenth century, he is one of the last of the masters of the old school; his works much resemble those of Pietro Perugino; at the same time they are more fully developed in form and of wonderful force of colouring; in expression also many of his heads are admirable.

He lived and worked for a long time as his son does now, being one of the principals in a conspiracy of the people against the government, he was compelled to fly, and he took refuge in France. Lanzi says that he would not have been hanged, had he not been protected by the Observanti monks who concealed him for some time in a tomb. He succeeded in making his escape, and joined II Rosso in France, where in all probability he spent his days, not looking forward, as nothing further is known of him, and he does not appear to have left any works in France.

There are still several excellent paintings, both in oil and in fresco, by Pacchiarotto, in Siena. There is a beautiful altar-piece in San Cristoforo; and some excellent frescoes in Santa Caterina and San Bernardino. Speth takes particular notice of these frescoes in his "Art in Italy," and terms Pacchiarotto the second hero of the Sieneese school—Ranzi, calls Sodoma, being the first. They are highly praised also by Lanzi. In Santa Caterina is the visit of St. Catherine of Siena to the holy of St. Agnes of Montepulciano, in which are heads and figures worthy of Raphael. According to Speth these works can be justly compared with Raphael's alone, and he adds that designating Pacchiarotto as of the school of Perugino, is only magnifying the injustice he had already understood in having his works long reported as the works of Perugino. If therefore he were the pupil of Perugino, what Perugino supplied was only the spark, says Speth, which in Pacchiarotto grew into a flame.

Pacchiarotto has suffered the same misfortune that many other excellent masters have undergone, owing to their being omitted by Vasari—merits which have remained long unrecognized. Pacchiarotto is probably the Girolamo di Pace his father, who is casually mentioned by Vasari in speaking of Il Sodoma; they painted together in San Bernardino.

There are two beautiful small easel paintings in oil and on wood in the Pinacothek at Munich by Pacchiarotto—San Francisco d'Assisi, and the Madonna and Child, with four angels in the background; half-length figures in both. They are two of the best pictures in the collection, in character, colour, and execution. They are among the finest pictures of the early Italian schools of painting. They were formerly in the church of San Bernardino at Siena, but were purchased about 1818 by the present King of Bavaria, Ludwig I., then prince.

(Lanzi, Storia Pittorica, &c.; Speth, Kunst in Italian, vol. ii.)

PACHECO, FRANCISCO, was born of a good family at Seville, in 1571, according to his own account, which is nine years earlier than the date given by Palomino. He was nephew of Francisco Pacheco, canon of the cathedral of Seville, a distinguished divine and a celebrated Latin poet.

Pacheco's master was Luis Fernandez, a painter of negroes &c. at Seville; he never was in Italy, as Palomino has wrongly inferred from two passages in his treatise on painting; he studied exclusively in Seville. His first works worthy of notice were two large flags or standards for the Spanish fleet of New Spain and Tierrafranca, painted in 1594, in oil on crimson damask, each thirty yards by fifty; the paintings with the arms of Spain, and St. Joseph on horseback, with rich borders and other decorations. He was one of the principal painters employed on the great decorations of the funeral or catafalque of Philip II. of Spain in the cathedral of Seville in 1621. He had been a subject of suspicion in Seville who properly painted and gilded statues—el primer no es encarna y estara bien; las estatuas; thin colour was painted over the gold. He was the first likewise who painted the figures of the Virgin of the Rosary in Seville; there are several works of both descriptions by Pacheco in Seville.

In 1600 he was appointed, together with Alonso Vasquez, to paint a series of large pictures illustrating the life of St. Ramon for the cloister of the convent of the Merced. In 1603 he executed some works in distemper in the palace of Don Fernando Henriquez de Ribera, third duke de Alcaza, from the story of Don Alvaro and Dona Elvira.

It was not till 1611 that he visited Toledo, Madrid and the Escorial, and saw the great works of Titian and other celebrated masters, Spanish and Italian. The sight of the excellent works of Titian, and of the altar-piece of the Virgin in him forcibly with the varied and incessant application requisite to form a great painter. Accordingly upon his return to Seville he opened a systematic academy of the arts, as well for his own improvement as for the benefit of the rising artists of Seville; and the fact alone that Alonzo Cano and Velasquez were two of his scholars, shows that his system worked with some effect. The improvement thus introduced may be termed an elementary instruction, and from the true principles of art, is shown by his great picture of the Last Judgment, an altar-piece finished in 1614 for the nuns of the convent of St. Isabel, which he has himself described at great length in his treatise on painting. Soult made a magazine of this convent during his occupation of Andalusia, and the picture was probably removed. It was a large work containing many figures and many incidents, but Pacheco received only 700 ducats for it. On one part of it was inscribed "Futurum ad Finem Sacclorum Judicium Franciscus Paccicos Romulanus depingebat. Seculii a judicia natali v. anno xl.

In 1618 Pacheco was appointed by the Inquisition one of the guardians of the public morals, in as far as he was made censor of all the pictures which were exposed for sale in Seville; nakedness was prohibited, and it was Pacheco's business to see that no picture of a naked female of the size of life, if of any other size. It reflects the jealous morality of the Inquisition even in its portraits. Prudery was carried so far in Spain, that in the time of Ferdinand VII., even all the great Italian works which could be reproached with nudities were removed from the galleries, and were condemned to a distinct set of apartments called the Galeria Reservada, and only opened to view to those who had a special permission. There is a Cabinet de Objets Réservés at Naples, and though this is separated from the rest of the collection with reason, there is no difficulty whatever in obtaining admission into it; but the Galeria Reservada of Madrid is of a very different kind, and comprises the most celebrated pictures—both old and modern—and the separation of such works from the general collection is a greater evidence of subjective immorality than of objective indecency. Mr. Ford, in his "Handbook of Spain," terms this cabinet a sort of National Museum, into which were banished all decent pictures whose nudities might corrupt the purity of Madrid; where the Italian and Flemish Leda, Danaë, and other improper ladies, blushed unseen, lumped together like the naughty epigrams of Martial when collected into one appendix in well-intentioned editions. All these pictures were the works of foreigners. 'Nothing,' says Mr. Ford, p. 116, 'gave the holy tribunal greater annoyance than how Adam and Eve in Paradise, the blessed souls burning in purgatory, the lady who tempted St. Anthony, or the Last Day of Judgment, were to be painted, circumstances in which small-clothes and long-clothes would be highly misapplied.' Both Palomino (ii. 187) and Pacheco (201) handle these delicate subjects very tenderly. Describing the celebrated Judgment of Martin de Vos, at Seville, Pacheco relates that when it was finished, ‘in an instant, without any sound or noise before it again, he would face a hurricane in the Gulf of Bremuda; the moral effect of the awful Day of Judgment was so much counter-balanced by the immoral deshabile.'

In 1633 Pacheco was in a sad case, in company with his distinguished scholar and son-in-law Velasquez; and he remained two years in the Spanish capital. Velasquez went
to Madrid by the invitation of the duke de Olivares, who procured him the appointment of painter to the king, Philip IV. It was at this time that Velazquez painted his equestrian portrait of Philip, upon which Pacheco wrote a sonnet, in which Philip was compared with Alexander, and Velazquez with Apelles (C. F. S. 161). Pacheco, during this visit to Madrid, among many other works, executed one which hardly accords with the present notions of the occupation of a great painter, though it has been praised by great artists, and very eagerly sought by publishers and men of taste; it was common in the time of Plato and of Alexander. [NICIAN, P. C. S.]. Pacheco dressed, gilded, and painted (estofo) for the duchess of Olivares, a statue, probably of Venus, which she may have wished to place in the temple of Venus de Monte allegra for 2000 reals. The work was much admired, and by none more than Eugenio Cazes, who, says Cean Bermudez, estimated the decoration at 500 duces. What this process exactly was it is not evident from this mere mention; but the object generally in these painted wooden images appears to have been to obtain an exact imitation in the minutest detail, personal and facial. The effect of such images, called Faseos, must be experienced to be comprehended. The Spaniards dress them as well as paint them. Their churches were crowded with such works; but most have now been removed to museums.

Pacheco returned to Seville, where his house became a chief resort of all men of art, of literature, and of taste, and among his most intimate associates were the Jesuits of Seville, who, under the patronage of the Jesuits, the Arte de la Pintura, and were indeed the authors of that part which is devoted to sacred art, and doubtless to them is due the eastern moral which characterizes Pacheco's principles of art. He is noticed above as having been one of the first to paint images properly. He published an essay partly on this subject in 1622, complaining of sculptors painting their own statues. But the generality of Doradores and Estafadores worked so badly, that such sculptors as Juan Martinez Montafies and Alonso Cane felt compelled to dress and colour their own statues. Pacheco however coloured many statues for Montafies, including the St. Jerome of the monastery of San Sprintone, Montafies generally being employed with his employer. He was also allowed to superintend the toilet of his own statues. Mr. Ford gives some curious details about the toilets of these Spanish images. No man is allowed in Spain to undress the Paseo, or Sagrauds, or Imaginies of the Virgin; and some images had their mistresses of the robes (Comerena Mayor) and a chamber (Comerena) where their toilet was made. The duty has, however, now devolved upon old maids; and ha quedado para vestir imagines—he has gone to dress images, has become a term of reproach. Embroidering rich dresses for images of the Virgin is still a great occupation with the rich and pious ladies of Spain. Similar customs prevailed with the saints. But the court of Madrid, says Mr. Ford, paid more attention to the decorum and propriety of costume than the Spanish clergy. In the remote villages and in the mendicant convents the most ridiculous masquerades were exhibited, such as the Sevillan, with wigs and painted faces, speaking figures have only heads, feet, and arms, the bodies being mere blocks, because destined to be covered with drapery; they are called Imagines vestir. Before the French occupation of Spain there were fifty of these images in Seville alone, which were carried in various processions in the holy week, and on other great occasions.

Pacheco died at Seville in 1654. His works, though not vigorous, are correct in form, effective in light and shade, studied in composition, and simple in attitude; but they have little colour, are dry, and rather feeble or timid in their handling. These defects are more apparent when his pictures are seen together with the works of other Andalusian painters who have generally made colouring their principal study, and have comparatively neglected purity of form. Besides many religious pictures, he painted or drew in crayons nearly four hundred portraits, the best of which is that of his own wife. One of his sisters also was Miguel Cervantes.

His Arte de Pintura, en Antigüedad, y Grandezas, etc., Seville, 1649, pp. 641, a remarkably scarce book, is considered an indispensable guide by the painters of the school of Seville, it is very elementary, and is said also to be a work of great learning on the subject, and is held throughout Spain to be the best work on painting in the Spanish language: it is in three separate parts, theory, practice, and historical. His works are seldom seen out of Seville; and he is even very inadequately represented in the splendid gallery of the Prado at Madrid.

His masterpiece is, or perhaps rather was, the Altarpiece of the Archdeacon Michael expelling Satan from Paradise, which was painted in the church of San Alberto at Seville; but this church was one of Soul's magazines. There are still at Seville an altarpiece of the Conception at San Lorenzo, two pictures of San Fernando in San Clor, a picture in San Alberto. The methodic system of Cean Bermudez to mention the locality of all the most celebrated works of the great Spanish masters, eventually cost Spain the greater portion of these works, for his Dictionary was, at the time of its publication, an encyclopaedia and an inventory of what was valuable, and directed them to the places where these works were to be found. Not a moiety of the works of Pacheco described by Bermudez as at Seville have now to be found; the portrait of himself is in the Spanish museum in the Louvre. Pacheco collected the poems of his friend Hernandez de Herrera, and published them with a portrait, in 1619. His own poems do not appear ever to have been published in a collected form. Bermudez has printed a few in his Dictionary. (Cean Bermudez, Diccionario Historico de los mas Ilustres Profesores de los Bienes Artes en Espana.)

PACHYCORUMUS, a genus of Cephalodaid fossil fishes, from the lias of England and Wirtemberg. (Agassiz.)

PACHYCOPHAUS, a genus of fossil fishes from Shoppeny.

PACHYODON, a genus of Dimyarian Conchifera, fossil in the lias and oolites. (Strickland.)

This is the genus Cardin-eia of Agassiz, and includes part of the Unionidea of Sowerby.

PACHYPTERIS, a genus of fossil Ferns, from the oolite of Yorkshire. (Brongniart.)

PACKING-PRESS. The hydraulic press invented by Mr. Bramah, besides being used to draw piles, trees, \\n
equipment, and to prove the strength of materials, is frequently employed to pack or compress bales of linen, cotton, and the like goods into small dimensions for the convenience of transport. A description of this machine has been given under HYDRAULICS, P. C.; and it is intended here merely to notice the method employed by Mr. Barlow to determine the thickness which the cylinder should have in order that its strength may bear without the strain to which it is subject from the pressure of the fluid within it.

Within any horizontal section of the cylinder the tendency of the contiguous particles of metal to separate from one another in a direction perpendicular to a diameter passing through them, in consequence of the expansion produced by the pressure of the fluid, becomes continually less from the interior to the exterior circumference of the section, and is inversely proportional to the distances of the particles from the axis of the cylinder; and the cohesive power of the particles is, by the laws of elasticity, proportional to their separation, while the strain produced by the pressure of the fluid varies as the square of the distance of any points from that part from the axis. It follows that the resistance opposed at such a part of a section to the momentum of the pressure is inversely proportional to the square of the distance from the axis.

Therefore r representing the radius of the interior surface of the cylinder, r the whole thickness, and x any variable distance from the interior surface towards the exterior, all in inches; then \( f = \int_0^r \frac{1}{r^2} dx \), or multiplied by 2 \( \pi \), the circumference (rad. = 1), and by the force of cohesion on a square inch of the metal, will express the resistance produced by an annulus which is one inch deep in a direction parallel to the axis.

That integral, for the whole thickness \( r \), is \( r \pi \); therefore \( f \) (in pounds) denoting the force of cohesion, \( 2\pi r f \) expresses the whole resistance.

If \( f \) (in pounds) represent the force on a square inch of the interior surface, by which the pressure of the fluid tends to strain the cylinder, \( 2\pi r f \) will denote the whole strain on the same annulus; therefore, equating the strength and strain, there is obtained

\[ \frac{f}{r} = \frac{\pi}{2} \]

This value of \( f \) expresses the required thickness.

PACO. [Llama, P. C.]
talent of every kind. In 1813 he performed at Milan; five years after, at Turin; and subsequently at Florence and Naples. In 1818 and 1819 Luigi Sanifici, the violinist and composer, Mayseder, asked him how he produced such new effects. His reply was characteristic of a selfish mind—"Chacun a ses secrets." In that capital he was accused of having injured the health of his ever having been married, which could not be produced. Then he was charged with having polargarded his mistress. This he also publicly refuted. The fact is that he knew better how to make music with friends who were captivated by the visit of a truly great musician, Rossini. Even this renowned composer was carried away by the current of popular opinion. Being asked how he liked the new violinist, he replied, 'I have wept but three times in my life: first, on the failure of my earliest operas; the second time, when in a boat with some friends, a turkey stuffed with trifles (un disole ours trifles), provided for our dinner, tumbled into the water; and, thirdly, on hearing Paganini for the first time.' The public of Brussels, however, were moved in a very different manner. According to M. Fétis, Paganini's performance at a concert given by him in that city, produced only laughter, which was increased during the whole of it. He arrived in England in 1831, and immediately announced a concert at the Italian Opera-House, at a price which, if accorded to any other artist, would have yielded large profits. He was to sail for the Continent, of the gulf of the British public, of the wealth of the aristocratic classes, and of their lavish expenditure on foreign performers; but the attempt was too audacious, for even these, and he was compelled to abate his demand, though he succeeded in drawing audiences fifteen nights in that season at the ordinary high prices of the King's Theatre. He also gave concerts in other parts of London, and performed at benefits, always taking at these a large proportion of the proceeds, and frequently the whole. He visited most of our great towns, where his good fortune still attended him. He was asked to play at the Commemoration Festival at Oxford, in 1834, and demanded 1000 guineas for his assistance at three concerts. Need we add that his terms were scornfully rejected?

Paganini died at Nice in 1840, of a diseased larynx (glottis laryngis). By his will, dated 1837, he gave his two sisters legacies of 60,000 and 70,000 francs; his mother a pension of 1200; the mother of his son Achillino (a Jewess of Milan) a similar pension; and the rest of his fortune, amounting to four millions francs, divided among them. Thebes and other facts before related, we give on the authority of the Biographie Universelle.

Paganini certainly was a man of genius and a great performer, but scorching to his bones, and the violin was almost marvellous, though he made an ignoble use of his power by employing it to captivate the mob of pretended amateurs by facts little better than sleight-of-hand. His performances, as well as the effect of his刘al, were so grand, that the harmonics, were very extraordinary; but why, as was asked at the time, he confined to one string when there are four at command that would answer every musical purpose so much better? His tone was pure though not strong, his strings having been of smaller diameter than usual, to enable him to strain them at pleasure; for he tuned his instrument most capriciously. He could be a very expressive player: we have heard him produce effects deeply pathetic. His argument evinced his knowledge of harmony, and some few of his compositions exhibit many original traits. But money was his object, and he attained it. Were the French, continuing their practice of not uncommon acts of violence in the Spring of Paganini's life into a dramatic form, 'All for gain, or fair fame well lost,' would make an appropriate title to the piece. (Biographie Universelle, Supplement : Harmonicon.)

PAGGI, GIROLAMO, proceeded to Genoa in 1554, was the pupil of Luca Cambiaso, and was distinguished chiefly as a painter, but he was also a sculptor and architect. About the year 1600 he was occupied with an expedition to search for the treasure of an unfortunate homicide which the absurd conduct of a friend brought upon him. Paggi went to Florence, and, under the protection of the grand-dukes Francesco I. and Ferdinando, they were both proceeded to, until he was recalled through Archbishop Sinismitus, afterwards
PAUL AUGUSTIN, a distinguished French sculptor, was born at Paris in 1730, and was the pupil of J. B. Le Moine, likewise a sculptor of excellence. Paou obtained the grand prize for sculpture in the French Academy, in 1748, and accordingly was sent as a pensioner of the French government to Rome, where he remained twelve years. Gabet mentions that Paou was the sculptor of about two hundred works, in bronze, marble, stone, wood, and even in paper or pastebord; and he gives a list of some of those which he ex- hibited. In 1769 he exhibited a sketch of the tomb of Sis- nius, King of Poland, and father-in-law of Louis V.; a statue of the Duchess of Mag- marin, representing Love as ruler of the elements; and four large colossal figures in stone for the garden of the Palais-Royal, representing Mars, Prudence, Liberalty, and Apollo. The present article is directed particularly to the works of the sculptor, and the connection in the history of his life is chiefly the report of the Academy, of the Luxembourg; and of the Cathedral of Orleans, and the Palais Royal. The sculptor of the façade of the Palais-Royal, ordered by Louis XVI. He executed also the sculptures of the Salle de l'École des Fils, of the Palais Bourbon; and of the Cathedral of Orleans, and also the Naïades of the south and west faces of the Fontaine de l' Innocent. He died at Paris in 1809. He was made one of the professors of the French Academy of Arts in 1767; and was subsequently a member of the British Museum; and of the British Institution. He was natural his- torically, and was so far the exponent of his own character. His son Jacques Augustin Paou was a painter of great merit. (Gabet, Dictionnaire des Artistes de l'École Française, &c.)

PALEOGRAPHY (from Gr. palaios, 'old,' and graphe, 'writing') is a term applied to express the knowledge of the ancient styles of writing, or the study of the characters and illuminations of ancient manuscripts. Paleography is a comparatively recent study respecting its ornaments, but it has very lately been the subject of much laborious application in all respects; and the age of a MS. may be now approximated from the class of its characters in part by its state and texture, but cannot with any strict elucidation. The present article is directed particularly to the ornament and general illumination of ancient MSS., and their connection with the progress of painting, and the taste and theory of the writer; or to the study of MSS. literature, which is treated of in the 'Penny Cyclopedia.' The whole subject is perfectly illustrated, generally, in the splendid work recently published in Paris by Champollion Figeac, and Aimé Champollion Fils, which contains fac-similes from most of the principal MSS. extant in Europe, admirably executed by Silvaste (Paléographie Universelle, Collection de Fac-Similes d'Écritures de tous les Peuples et de tous les Temps, par M. Silvaste, 1839-42, 4 vol.)

The first work which treats of this subject with regard to ornament is D'feldin's Bibliographie Decamerorum, published in 1817, which was followed by the more comprehensive work of D'Agincourt, History of the Manuscripts of the Italian School, but which treats chiefly of Greek and Italian MSS., and the illustrations are uncoloured. D'Agincourt was the first to proungulate the treasures of the Vatican Library in this depart- ment, and it was one of his most beautiful works. The life of Mr. Shaw, on this subject was published in London, in 1833, Illuminated Ornaments selected from MSS. and early Printed Books, from the Sixth to the Seventeenth Century, drawn and engraved, with descriptive notices, by Sir F. Morden, keeper of the MSS. in the British Museum. There are many papers on this subject in the Archæologia; and a series of articles on the Progress of the Art of Illumination in various countries, with fac-similes of manuscripts, was published in the Penny Magazine of 1839.

The Illumination of MSS. was in practice among the ancient Romans. This is known from passages in ancient writers, though there are no MSS. extant of any importance from the third century of the Christian era. Portraits were sometimes prefixed to the writings of authors: Martial (ix. 186) mentions one of Virgil which was prefixed to a MS. of his works; and Virgil himself, in the Eclogues, lines 835, 836, mentions the portraits of 700 distinguished men in his writings, and dis- persed them over all parts of the world.

The illuminating of MSS. is generally considered as a con- necting link between the art of the miniaturist, and the art of the painter. At the revival of painting MSS. were illuminated by painters, the calligraphists must have been always a distinct class, and even the initial letters and borders were executed by distinct persons. But it is evident from the fact that some MSS. want the initial letters altogether, the spaces being left to be filled in by the proper artist. Though many illuminators of MSS. or miniaturists, at about the revival of painting became subsequently great painters, it is not likely that painters became the illuminators of MSS. at any time, beyond the execution of the miniatures which were attached to them. There are few even moderately good miniatures as works of art to be found in any MSS., and the best of all are those executed by the celebrated Melimg and his nearly contemporary Giulio Clovio, a native of Croix, who died 1578, aged eighty: executed therefore at a period when the art of painting was at its highest state of perfection, which shows that the influence of the great works which Flanders and Italy then sounded reached the decoration of MSS. as well as other objects of taste, the less influenced by the great masters. But it is plain that it would be difficult to show that painting was ever in any way improved or even preserved by the illumination of MSS. The miniaturist (from minium or minito, red lead; Jinty and Vitruvius sometimes mean vermilion) has always to have been the only painters of the middle ages, but this is an incorrect assumption, and that the miniaturist also were the revivers of painting in the tenth and eleventh centuries is a theory founded on assumption. Constantinople always had its painters, and there is a Latin work extant, of as early a date probably as the ninth century, which treats of painting and of the MSS. of that time, 'De Scriptoribus et Artistis pingendi,' not omitting painting in oil. There is a MS. of this work now in the British Museum; it is by Theophilus Presbyter, whom Leasimg supposed to be the same person as Tutilo or Tuttilo, a monk and painter, 'picture artist,' of the convent of St. Gall, in Switzerland. The work is printed in Leasimg's Beiträge zur Geschichte und Literatur, No. vi., Brunswick, 1781. (Tuttilo, P. C.)

Vinci, in the Life of Don Lorenzo, evidently informs us that the writers of letters were a distinct class after the revival of painting, for he notices Don Jacopo of Florence, a monk of the convent de'Angeli, of the fourteenth century, as the most of the MSS. were done by them, though it cannot be said to have been only in Tuscany but in the whole of Europe. He left his convent sixteen folio choral books with miniature illuminations by another monk of the same convent, Don Silvestro, and their skill was such that with two other MSS. of his the brother and the right hands were embalmed after their death and preserved in a tabernacle.

It appears that the earliest MSS. extant of Greek and Roman origin are not much ornamented, their embellishments consisting in little more than the occasional use of red ink for titles or commencements of books. No ornaments have been found in the Herculaneum papyri. The Egyptian papyri are written in various colours; they contain mythological figures in red, blue, yellow, green, and white.

The most celebrated collection of Illuminated MSS. is that of the Vatican, already noticed, which, among its 24,000 MSS., contains the Monuments of the Early Church of the East, and notices upwards of fifty valuable MSS. in this collection, and gives specimens of the style of decoration, in design, from most of them. The following are the most remarkable of this collection: among figures, the miniature Virgil, in one of the Rossa, vol. ii. pt. 2, p. 945-363);--Of the Western or Latin MSS. the earliest is probably the Virgil (Vatican, No. 225), containing 50 miniatures, 44 of which are from the Aureliana, and in the introduction of which is an epigram by Sir F. Morden, keeper of the MSS. in the British Museum. There are many papers on this subject in the Archæologia; and a series of articles on the Progress of the Art of Illumination in various countries, with fac-similes of manuscripts, was published in the Penny Magazine of 1839.
other accessories are picked out with gold; the date of this MS. is supposed to be not earlier than the fourth century. Another MS. with MS. 160 is also in the possession of Cardinal Bembo. At the commencement of the MS. is a portrait of Terence, and at the beginning of each comedy is a picture of masks: in the text are representations of more important literary characters attached. This MS. is supposed to be of the ninth century; and the illustrations are thought to be copies of earlier works, on account of the superiority of the designs to the more primitive ones in the figures; the drawing is very bad. (D'Agincourt, pl. xxx., xxxvi.)

The writer of the MS. was Hrodgarius (Rodgar), from his name apparently a German. There is another Virgil in this collection which is signed with the name of Pantaleon, (Vatican, No. 630), and is dated in 1085, and distinguished for its writing, initial letters, and arabesque marginal decorations; it contains only one miniature—the author writing. A still more remarkable MS. is the MS. 92, also in the Panoplia, fortifications against heresies (Vatican, No. 666), executed by order of the Emperor Alexius Comnenus (1081—1118). In this MS. are three large illustrations on gold ground: the two, representing the two sons of the same leaf—on one the fathers the Greek church are bringing the materials of the book, and on the other, the emperor is receiving them; above is an apostrophe of the Saviour, with the dieties of the same period in the third illustration, the emperor is presenting the finished work to the Saviour seated on his throne. The figures of these paintings are perhaps the best extant of this or any preceding period; they are about nine inches high, are brilliantly coloured, and the heads have much character: the costume of the emperor is on both occasions very complete; it is quite oriental, and bears no resemblance to the ancient costume. (D'Agincourt, pl. lxi.)

There is also a beautiful MS. of the four gospels, or Evangelium, executed in 1128, in the reign of Johannes Comnenus. The illustrations of this MS. are—Christ seated between Justice and Love, and another Christ crowned; but the third one which he has with his right hand the emperor, with his left the emperor's son Alexius; the Evangelists writing; the birth of the Saviour; his baptism; the birth of John the Baptist; and others. Of this MS. is also a MS. dates from the ninth century. The vegetable characters are large: the leaves are picked out with gold, and the heads have much character: the costume of the emperor is on both occasions very complete; it is quite oriental, and bears no resemblance to the ancient costume. (D'Agincourt, pl. lxi.)

The Byzantine MSS., of which there are many in the Vatican, are generally divided into two classes: one, the works are well executed, but the horses and the human figures, particularly, are bad. (D'Agincourt, pl. lxxxiii.)

The Byzantine MSS., of which there are many in the Vatican, illustrates the style of the early Christian illustrations: in the Byzantine they are very inferior to the earlier Christian illustrations: in the extremites they all have the same characteristic imperfections of Byzantine art, but in treatment, in costume, and in the manner of treatment, they appear to be modern substitutes. (Jongmans, lvi., and Ai, and Montfaucon, pl. xxxv.)

These MSS. are also the celebrated Monologium (Vatican, No. 1618), or part of a Greek Calendar, from September to February, with 450 miniatures upon gold ground, illustrating the life of Christ, and of all the saints whose holiday occurs in these months of the year. The miniatures, according to names inscribed upon them, were painted by Pantaleon, Simeon, Michael Blachernitas, Georgius, Menas, Simeon Blachernitas, Michael Micros, and Nestor. They are extremely poor in execution, but have considerable merit in the expression of the heads, in the draperies, and detail of execution: the figures in action are the most defective; those in repose are frequently natural. Their general merit is the subject represented in the lives of the saints. There are many characteristic Byzantine buildings introduced in the background. This MS. was executed by the order of the Emperor Basilus II., called Feodoricus, finished by Eustathius, and have been procured from Constantiopol by Lodovico Sforza, Duke of Milan. It was presented to Paul V. by Cardinal Sfondrato, and placed in the Vatican Library in 1615. Cardinal Ambrì-

The manuscript is written on vellum, in black letters, together with a Latin translation, but the engravings of this edition are very inferior to the originals. (D'Agincourt, pl. xxxi.—xxxiii.)

The rest of the Calendar was supplied from a MS. in the Library of Grotta Ferrata, in which there are no illustrations.

Platner is of opinion that the best Greek MSS. are those of the period of the Comnenus emperors (1056—1382), in both the monasteries of Constantinople and of the Crusaders; and particularly during the reigns of Alexius I., Johannes II., and Manuel I., and this opinion is borne out by the illustrations of D'Agincourt. Of these MSS., the Homilies of Gregory Nazianzen (Vatican, No. 468), dated in 1069, and distinguished for its writing, initial letters, and arabesque marginal decorations; it contains only one miniature—the author writing. A still more remarkable MS. is the MS. 92, also in the Panoplia, fortifications against heresies (Vatican, No. 666), executed by order of the Emperor Alexius Comnenus (1081—1118). In this MS. are three large illustrations on gold ground: the two, representing the two sons of the same leaf—on one the fathers the Greek church are bringing the materials of the book, and on the other, the emperor is receiving them; above is an apostrophe of the Saviour, with the dieties of the same period in the third illustration, the emperor is presenting the finished work to the Saviour seated on his throne. The figures of these paintings are perhaps the best extant of this or any preceding period; they are about nine inches high, are brilliantly coloured, and the heads have much character: the costume of the emperor is on both occasions very complete; it is quite oriental, and bears no resemblance to the ancient costume. (D'Agincourt, pl. lxi.)

There is also a beautiful MS. of the four gospels, or Evangelium, executed in 1128, in the reign of Johannes Comnenus. The illustrations of this MS. are—Christ seated between Justice and Love, and another Christ crowned; but the third one which he has with his right hand the emperor, with his left the emperor's son Alexius; the Evangelists writing; the birth of the Saviour; his baptism; the birth of John the Baptist; and others. Of this MS. is also a MS. dates from the ninth century. The vegetable characters are large: the leaves are picked out with gold, and the heads have much character: the costume of the emperor is on both occasions very complete; it is quite oriental, and bears no resemblance to the ancient costume. (D'Agincourt, pl. lxi.)

The Byzantine MSS., of which there are many in the Vatican, are generally divided into two classes: one, the works are well executed, but the horses and the human figures, particularly, are bad. (D'Agincourt, pl. lxxxiii.)

The Byzantine MSS., of which there are many in the Vatican, illustrates the style of the early Christian illustrations: in the Byzantine they are very inferior to the earlier Christian illustrations: in the extremites they all have the same characteristic imperfections of Byzantine art, but in treatment, in costume, and in the manner of treatment, they appear to be modern substitutes. (Jongmans, lvi., and Ai, and Montfaucon, pl. xxxv.)

These MSS. are also the celebrated Monologium (Vatican, No. 1618), or part of a Greek Calendar, from September to February, with 450 miniatures upon gold ground, illustrating the life of Christ, and of all the saints whose holiday occurs in these months of the year. The miniatures, according to names inscribed upon them, were painted by Pantaleon, Simeon, Michael Blachernitas, Georgius, Menas, Simeon Blachernitas, Michael Micros, and Nestor. They are extremely poor in execution, but have considerable merit in the expression of the heads, in the draperies, and detail of execution: the figures in action are the most defective; those in repose are frequently natural. Their general merit is the subject represented in the lives of the saints. There are many characteristic Byzantine buildings introduced in the background. This MS. was executed by the order of the Emperor Basilus II., called Feodoricus, finished by Eustathius, and have been procured from Constantinople by Lodovico Sforza, Duke of Milan. It was presented to Paul V. by Cardinal Sfondrato, and placed in the Vatican Library in 1615. Cardinal Ambrì-
or Attavante, a celebrated miniature painter, also executed miniatures for Matthias Corvinus, but Vasari adds that all the MSS. for the duke Federigo between the years 1460 and 1482, the last is that of his death, and 1476 is the year in which he was presented with the order of the Garter by Edward IV. The decoration of this order is embellished with the figures of the sovereign and the three parts. (D'Agnicourt, pl. ixxvii.) Of the sixteenth century there are, with the exception of Giulio Clovio's and Memling's, scarcely any MSS. worthy of the time, and those of Clovio are put to an escape from such of other earlier masters; they are executed in what is at present understood by water-colours, while those of earlier masters are done in body colours, or a species of distemper, a guesso, or a colaf the lights are relieved in white, gold, and silver. The design is in both cases previously put in fine outline. In the sixteenth century Vasari, spent nine years in painting the twenty-six miniatures in the MS. in the Library at Milan, dedicated to the Cardinal Alessandro Farnese, now in the Royal Library at Naples. The works of Clovio, however, are not superior, and in some respects are not even equal to those of his predecessor Memling, who are more masculine in their execution. The illuminations of Memling and his scholars are in the opinion of Schorn the finest paintings of their class extant: the excellency of his oil paintings; they are painted in body colours and quite free from the dark outlines of the Greek and Italian MSS., and have no gold but what is put on with the pencil. The most remarkable work of this class by Memling, in which he was assisted by Gerhard on Ghent and Livin of Antwerp, is the celebrated missal of Cardinal Grimani in the Library of St. Mark at Venice (it is described in the Kunstblatt of 1833); Memling died considerably advanced in age in the beginning of the sixteenth century. (Memling, P. C. S.) There were also several good miniatures or miniaturists of earlier centuries, who can be mentioned by name. Oderigi of Gubbio, and his pupil Paolo Bolognese, who are noticed by Dante, are two of the earliest:

Oderigi died about 1300, Franco was still living in 1313. Simone Memmi, the pupil of Laura, and the friend of Petrarch, was likewise an illuminator of MSS. There is a MS. of Virgil in the Biblioteca Comunale at Gubbio, which was executed for the Cardinal Alessandro Farnese, now in the Royal Library at Naples. The works of Clovio, however, are not superior, and in some respects are not even equal to those of his predecessor Memling, who are more masculine in their execution. The illuminations of Memling and his scholars are in the opinion of Schorn the finest paintings of their class extant: the excellency of his oil paintings; they are painted in body colours and quite free from the dark outlines of the Greek and Italian MSS., and have no gold but what is put on with the pencil. The most beautiful MSS. of the eighth, ninth, and tenth centuries are those in England, and especially in the tenth century. The Harleian copy of the Gospels, No. 2788, and the Bible and Hours of Charles the Bald, at Paris, are among the finest examples of this kind of writing extant. (There are specimens of the 11th century, called writing, which is a portrait of Edgar between the Virgin and St. Peter. This MS. is much damaged, and the ink has fallen off in many places. In the fourteenth century gold and silver writing became again, especially in the Bibles and Pentecostals. With these altogether in the capitals, the initials were in general not larger than the other letters. The large illuminated initials are said to have commenced first among the Greeks about the close of the seventh century. In subsequent centuries large initials were usual, and they gradually became more complicated and elaborate down to the twelfth century, when they attained such a degree of size, ornament, and intricacy, that they have not since these respects been surpassed. These letters are ornamented with all kinds of fanciful figures, composed of men, animals, birds, fish, and flowers. Montfaucon, in his 'Palaeographia,' gives a complete alphabet from MSS. of the ninth and tenth centuries. He states that the capital letters are taken from the story of the text, Lettres Histoire; they occur most frequently in the Franco-Gallic MSS. In this alphabet a T is represented by a fox, and a B by a pomegranate; in its mouth horizontally, from the ends of which hang very rare objects. Charlemagne and his grandson Charles the Bald were great patrons of illuminations. Charlemagne's Bible in the Schuyler manuscript is one of the most splendid and the best example of ornamental calligraphy extant. There is another very inferiorly ornamented Bible, which is said to have belonged to Charlemagne, now in the British Museum, but which, according to Sir F. Madden, is of the time of Charles the Bald. It is described by Sir F. Madden in the Gentleman's Magazine for 1836; see also Penny Magazine, vol. viii., p. 92, 1839. It was purchased of M. de Spyvee-Passeval, who had bought it for the sum of 750 francs. The N.B. is of the large amount, for the comparatively small sum of 750 francs, he asked the trustees of the Museum originally 12,000 francs. The twelfth century is remarkable, says Sir F. Madden, for profusion of ornament and a graceful but intricate mode of illuminating capital letters, which renders it more easy to appreciate MSS. of this period than any other. See specimens in Shaw's 'Illuminated Ornaments,' &c., pl. ix. — xiv., where there are many varieties of initial letters. The prevailing colours are red, blue, and green, with gold and silver. In the following century red, blue, and white were more used, and the initial letters more elaborate; though the inferior effect is that they are mostly German and French. Illuminators were very numerous in the thirteenth century. In the library of Sir Thomas Phillipps, Bart., there is a MS. of this century, entitled 'Hagiography,' and totally unilluminated. In the French and English MSS. of the fourteenth century, initials in purple, red, and gold are very frequent, which contain figures of men and animals, and terminate in spiral scroll work, which extend along the upper and lower margin of the page, and support small groups or single figures of dogs, hares, apes, &c. much resembling the decorative etchings and woodcuts which have recently appeared in Germany, and also occasionally in England. A Psalter of Lord Braybrookes has beautiful examples of this style of decoration (Shaw's Illuminated Ornaments, &c., pl. xvi., xxi.). English illuminators were in no way behind their continental brethren, and the greatest manuscript extant on the Continent at the same period is the Benedictional of St. Ethelwold, belonging to the Duke of Devonshire, written and illuminated between 963 and 970, is the most complete example of the fourteenth century. This MS. contains the Life and Times of St. Ethelwold (then the most celebrated place in England for such works), named Godman, for Ethelwold, bishop of Winchester. It is a folio of 119 leaves of vellum, measuring 11½ inches in height and width, and contains 278 leaves with border and initial drawings; and it is considered the most valuable MS. of the Cavendish collection. See Mr. Gage's 'Dissertation on the St. Ethelwold Benedictional,' in the Archaeologia (vol. xxiv., p. 25), where all the illustrations are engraved. Another curious MS. of this time, now in the British Museum (Cott. MSS. Claudius B. iv.), is a remarkable MS. of the Anglo-Saxon period, and contains a Saxon calendar, in which the account of each month is headed by a drawing illustrating the agricultural occupations of the respective months of the year. The initials A. vi. is a remarkable MS. of the Anglo-Saxon period, drawn from the Charter of King Edgar to the new minster, or Hyde Abbey, at Winchester, in the year 966 (MSS. Cott., Vesp. a. viii.), is the only remarkable instance that occurs of gold writing in that period. It is of the eleventh century. No. 608 of the Harleian MS. contains a long series of illuminations of Anglo-Saxon customs, in very curious designs in outline, executed in various coloured inks; and though the execution is ridiculously slow, the subjects are many and various, and the execution of great beauty. In the Cott. MSS. Cleopatra C. viii. of the same period there is a comparatively very superior drawing of a party at meat drinking together; the poses of the figures are excellent, and the heads and hands are perfectly intelligible and expressive: it is engraved in the Penny Magazine, vol. viii., p. 70, 1839, where there are also a few other cuts from some of these MSS.

In the thirteenth and fourteenth centuries Saxo-English MSS. are comparatively rare; the majority of the MSS. of this period are French.

There is a Psalter in the British Museum, supposed to be of English origin, of the latter part of the thirteenth century, more probably of a later date, purchased by Lord Jerningham (Reg. MSS. 119, v. b. vii.), in which the drawing of the period is much better represented than in MSS. generally: some of the illuminations are in the character of the fifth part of the Italian frescoes of the fourteenth century, but it is evident that the illuminations of MSS. at all correspond in design with the highest state of the arts of their time. It is an English Psalter, and there are also fifty-six illuminations from the Old Testament, in transparent water-colours, in the usual style of such decorations, the designs being drawn in black outline, and the colours lightly washed in. These are followed by drawings of saints in body-colours, which are likewise prepared in black outlines; but in these body-colour drawings the outline is frequently painted over; then follows a Calendar. The greater part of the volume is however intended for the use of the laity, and richly ornamented with designs, many illustrating the history and habits of the time. This book was presented to Queen Mary in 1558, by her then pensioner, Dalby Smith. There are some French MSS. of the same period in which the illustrations are equally good, as the 'Life of St. Grat' and 'Les Gestes des Roys de France,' both folio volumes, with numerous illuminations. On the last page of the second is written 'C'est livre est a moy Houfrey Duc de Gloonestrue du don de l'executore de Sr. de Fance.' There is also a French MS., called the Metrical History of the Life of Richard II., preserved in the British Museum, with a series of finely illuminated illustrations. It is translated in the 'Archaeologia,' vol. iii., p. 270, by the Rev. John Webb. There are three cuts from these MSS. in the volume of the Penny Magazine already noticed.

One of the most interesting French MSS. of the fifteenth century is the celebrated Bedford Missal, executed for John Duke of Bedford and regent of France, in the reign of Henry VI., now in the possession of Sir John Tobin at Liverpool. It is 11 inches high and 7½ wide, and contains 59 illustrations nearly of the size of the page, and about 1000 very small illustrations, with borders and foliage, &c.; there is a copy of it in the British Museum. In this MS. is the only known portrait of the Duke of Bedford: the portrait of the duke, engraved by Vertue for the translation of Lapin's 'History of England,' was taken from the illumination, in which the duke, in a crimson robe embroidered with gold, is represented kneeling before St. George, who is dressed in a suit of armour, over which is the mantle of the Order of the Garter; behind the knight is his arms, and beneath are the words, 'presented by the Duke of Bedford to Henry VI., at the coronation in France: after passing into various hands, it was several times sold by public auction, and was last bought by Sir John Tobin, at Liverpool.'

There are also in the British Museum many illuminated French romances of the fifteenth century, which are particularly interesting as regards costume. Among the most attractive of these are two illuminated books, one of which is the Historie des Amours de Perceval (MSS. 4425), the collection presented by Talbot Earl of Shrewsbury to Margaret of Anjou (Royal MSS., 16 E. I.), and the poems of Christine de Pisan (Hali. 4431), while the festa of arms and chivalry, by the same author, is still preserved.
Fais d'Armes et de Chevalerie," written in French in London in 1434 (Harl. MSS. 4605), is so inferior in its illustrations, that it presents a great contrast between the states of the art of illuminating in the two countries at this time. The "Mansion of Personages," given in both, consists of similar figures; it is supposed to have been executed towards the close of the fifteenth century; it is a folio volume, measuring 16 inches high by 113/4 inches wide, and contains 185 leaves, illuminated in double columns, the initial letter of every paragraph being illuminated. This French poem is of the thirteenth century; it is a dream, and was commenced by William de Lorris and finished by his son, the composition is divided into 100 chapters, and contains 22,000 verses. It has been several times printed, and last at Paris in 1814, in 4 vols. 8vo. The British Museum MS. is considered the most beautiful of the poem extant; the illustrations are probably French. (Dibdin, Bibliographical Documen.)

The Anglo-Saxons were for many centuries among the best illuminators, and the Irish also obtained great celebrity in this art at an early period. This British or Hiberno-Saxon school of illumination shows a distinct character, as seen from the so-called 'Durham book,' or St. Cuthbert's Gospel, of the beginning of the eighth century, now in the British Museum. The initials, observe Sir F. Madden, are characterized by an extreme intricacy of pattern, interlacing of knots, in a diagonal or square form, sometimes interwoven with animals, and terminating in heads of serpents or birds, to which may be added the small dotted line or point at the edge of the larger letters. The Lombardic and Insular letters are tessellated and embossed. There are no British illuminations later than the reign of Henry VIII., and at this time they disappeared.

After the establishment of printing and consequent multiplication of books, MSS. became gradually more rare, though they were still occasionally executed as articles of luxury even as late as the sixteenth century; and then a system of bookbinding was adopted, like that of the present day, and a bonne livre, compared with that of printed books, must naturally have so limited the demand, that they only have been required as works of art and curiosities in calligraphy, not as books. The writing of many MSS. is so beautifully executed, that probably no movable type has ever equalled the manuscript characters in beauty, and they have perhaps not even been surpassed in equality of execution and finish. See the fac-similes in Sylvestre's Palaeographie Universelle. Perhaps the latest, says Sir F. Madden, or one of the latest illuminated missals, is the famous folio in the library of Rosen, which is nearly three feet high, and cost the monk of St. Andoche, who illuminated it, thirty years of labour: it was completed in 1682.

PALEOZOA/MIA, a genus of fossil Cycadean plants, from the oolithic and lias deposits of Yorkshire, Dorsetshire, and Oxfordshire.

PALAQUEIN (sometimes written Palanqueen, Palanquin, and Palacke), a kind of covered litter carried, by means of poles, upon the shoulders of men, which forms the principal conveyance of many Oriental states. A very minute description of an ordinary palanquin, together with an amusing account of a däkk or dëkk journey, which is the name given to the mode of travelling long distances by the palanquin, is given in Captain Collingwood's Voyages and Travels, 3rd series, vol. ii., chap. vi., where the palanquin is described as about six feet long by two and a half feet wide, and provided with conveniences which enable it to serve at night-time for a bed, and in the day-time for a parlour. In the front part is usually a broad shelf, with a drawer underneath, and a net stretched above it; and in the hinder part is often shelf or book, a neat cover of the same and other loose articles and books for hats, towels, &c. In each side of the palanquin are two doors, or sliding partitions, with Venetian blinds in the upper panel, and in each end are two small windows. As, owing to the heat of the country, travelling is performed much by night, palanquins are often furnished with a lamp at one corner, so fixed as to throw its light into the interior, but to be trimmed from outside. The bottom, or seat, is made of strips of rattan, like that of a case-bottomed chair, and is covered with a light elastic mattress stuffed with horse-hair or shavings produced in dressing the bamboo and rattan. Across the palanquin, about eighteen inches from the hinder end, is a broad bar with two narrow bars to rest against when sitting up, and towards the other end is a movable bar against which the feet may be placed as against the stretchers in a boat, which may be shifted nearer to or farther from the body by raising or lowering the palanquin, according to the length of the traveller's legs or his choice of position. In the space behind the back-cushion the bed-clothes and pillow are stowed away during the day; and the shoes, drawers, and nets afford facilities for the conveyance of teapots, canisters, shaving apparatus, scientific instruments, sketching materials, and a variety of personal necessaries. The porter is supposed to be a native of the place to which he is going, and to be privy to the best way to go, and to the safest, which is the most convenient road. The porter is often a person of business, and is usually to be seen accompanying the traveller be separated for a time from his heavy baggage. Articles may be laid beneath the mattress, and bottles and food placed in pockets attached to the corners of the palanquin. A cover of waxed cloth is affixed to the top in such a way that it may be rolled up when not wanted, and let down so as completely to envelop the palanquin, in rainy weather. A covered sedan-chair is generally in use. A palanquin is attached to each end of the palanquin, near the top, to carry it by; and to the foremost of these poles is suspended a rattan basket containing a water pitcher, or goglet, of porous earthenware; and also the water which exudes through the pores of the goglet is rapidly evaporated by the current of air, its contents are always kept cool in the hottest weather. The action of this apparatus is identical with that of the alcarazas of Spain, described under Coola, P.C., p. 495. On the hinder pole are carried, in like manner, a kettle, coffee-pot, and wooden wash-hand-basin. As the poles, which rest upon the shoulders of the bearers, are not elastic like those of a sedan-chair, Captain Hall states that a palanquin has not the same unpleasant motion as that vehicle; and Bishop Heber also, who gives an account of däkk travelling in the 'Narrative of a Journey through the Upper Provinces of India,' published in 1826, says that his palanquin motion is neither violent nor unpleasant, but that, being incessant, it is impossible to draw in a palanquin, and not very convenient to read, excepting a large print. In the first edition of this work there is a map of the country; which, it should be observed, is a great part of the country that bearers can, in an ordinary palanquin, place their shoulders beneath the poles, two at each end; but in passing over difficult ground two others will occasionally bear part of the weight. (Pall, 1st ed., p. 202.)

In most cases the bearers follow one another in a straight line; but in some districts it is the custom to proceed obliquely, in which case the sideways motion is said to be exasperatingly unpleasant to Venice. With a little care, running with their load, the bearers, who form a peculiar caste among the Hindus, keep up an incessant noise, sometimes like grunting or groaning, and sometimes expressing the character of a song, or of wild vociferation. Captain Hall has some curious remarks on this subject.

In the 'Pictorial Bible,' in illustration of a note on Solomon's Song, iii, 9, are representations of the Palæstra, or state palæon of Hindustan, and also of a similar vehicle used by the ancient Egyptians; and some further information on conveyances of this character is given in the article 'Litter.' (Burgess's Cyclopaedia.)

PALECHI/KUS, a genus of fossil Echinodermata, from the mountain-limestone of Ireland. (Scouler.)

PALS REGIA, a name occasionally applied to the village of Palestania, in the county of Galilee, where John the Baptist is said to have been born. It is generally supposed to be the same as the village of Rabbah, not far from the sea of Galilee. This village is well watered, and was esteemed a pleasant place, though it was not so flourishing as it once was. It was mentioned by Josephus, and by the early Fathers of the Church, and was the residence of a bishop. The village was visited by Cardinal Cullen in 1646, who ordered the bells to be struck thrice a day, in memory of the visit of St. Paul, when finding that Palestina had quitted a state of celibacy, which
all the higher appointments in the apostolic chapel enjoined, abruptly dismissed him, and for some time he felt severely his strained circumstances; then gladly accepted the place of Maestro di Capella of St. John in the Lateran, which he held for three years (1568–71), during which time he married Maria Maggiori; and in 1571 was restored to his post in the Vatican. Up to the year 1569 he composed many works for the church, among which Baini especially mentions three Graduals and six Properies published the same year by Dr. Burney, in his collection of music performed in the Capella Pontificia, it seems to us that these many-extolled compositions, consisting of the simplest counterpoint, must own their effect to place and high-wrought feelings.

During the above period, however, the Council of Trent, among other matters, took the state of ecclesiastical music into serious consideration, and appointed two cardinals whom they charged with its reform, who called to assist them a committee of eight selected from the college of chaplain singers. Much discussion arose out of the case. The cardinals reasonably demanded the abolition of all the secular tunes which had been recklessly foisted into the sacred service, many of them vulgar, some obscene, and required more simplicity in the music. The singers irritationally defended the melodies, and contended for the florid and elaborate. At length it was agreed that the cardinals should have the choice of three masses, but the third was considered as the perfection of art, and the singers, on whom a ray of common sense had now fallen, could not restrain their expressions of admiration even during its performance.

This is known under the title of 'the Mass of Pope Marcellus.' He applied all his powers on the work, and wrought himself up to the most enthralling pitch. On his return from the service Dr. Fordwad, Domini, illumina occulos meos. The pope, 'before whose presence the work had been performed, was enraptured, and compared it to the heavenly melodies which the apostle John heard in his ecstasie trance.' By this one great example the question was now forever set at rest," says Ranke (in his 'History of the Popes,' acknowledging Baini as his authority); 'a path was opened, in following which the most beautiful, the most touching works, even to those who are not of the church, were produced.

... This art, which had been perhaps more completely alienated from the spirit and service of the church than any other, now became the most closely connected with it. Not only were the spiritual attributes of the mass, its Spiritual sanctity and rapture were the favourite themes of poetry and painting. Music, which speaks a language more direct, more impressive, more adapted to ideal expression, than that of poetry, was here at its best. The picturesque, the imaginative, and thus subjugated all minds to her empire.' (Mrs. Austin's translation of Ranke, vol. i.) We here again find the warm expressions of an enthusiast, no doubt; but it must be borne in mind that the writer heard these compositions performed under peculiar circumstances of a very influencing nature—under the roof of the grandest temple in the world, with every advantage that the finest execution, a solemn unceasing for imposing effect, and the most exciting religious associations could bestow.

On the restoration of Palestrina to his office, his fame spread widely. Cardinal Faccio announced to him that Palestrina was restored, and, of his own accord, the composer that he might dedicate himself to his. To his other appointments was now added that of Maestro to the congregation of the Oratory. He also undertook the direction of the Palestrina school for the young churchmen. After this he was charged by Pope Gregory XIII. with the task of revising the Roman Gradual and Antiphoner, which, however, he did not live to complete—a duty performed by his successor, Cardinal Borromeo. However, his personal circumstances must have been much improved, for on his death-bed, after blessing his son, he added, 'I leave many unpublished works, and thanks to the Abbé de Baumé, the collection of his works is placed in the hands of that gentleman.' In January, 1594, it became evident that his life was rapidly drawing to a close; and on the 2nd of the following month, after receiving the last rites of the church from the hands of his friend (the future Saint) Filippo di Neri, he expired. Of his funeral, Terrizio (Grotte Vaticane, ii. 166) says, 'In St. Peter's church, near the altar of St. Simon and St. Jude, was interred, in consequence of a contract with the Cardinal, PUllin, of Palestrina, the great musical composer, and Maestro di Cappe- lia of this church. His funeral was attended by all the musicians of Rome, and 'Libera me, Domine,' as composed by his own hand, was sung. After being placed in the same church—when read in the kind of place for which it is adapted, and attended by pomp and pageantry, it strongly felt by all, and acts with irresistible force on sensitive minds. But in the concert-room or chamber, his composition, whether sacred or secular, bare, with few exceptions, no charms for hearers who have not cultivated a taste for simple, solid, airless harmony, or for the intricacies of fugal points well woven with a skill that owed more to study than genius. His works are exceedingly numerous, chiefly ecclesiastical; but including also many madrigals, now rarely performed, even in societies devoted to this species of music. Cleres as these are, their dryness is undeniable, and they are praised by many who derive no pleasure from their performance. Three of his motets are in use in our cathedrals, adapted by the learned and all-acclaimed Dr. Gardel, to which the English version of the 16th century was added. In Pope Clement's words, 'We have heard with our ears,' and third, 'Not unto us,' are printed in Dr. Arnold's Collection of Catholic Music, the second volume in its original state in Hawkins's History of Music, iii. 175. Of his motets was one in the Missa Transalpina (1588), a work containing twenty madrigals by Italian masters; and this is the only composition of Palestrina noticed in La Musica Magistrale (1687); an elegant, interesting volume, containing the words of 365 compositions, chiefly madrigals, 'of the Elizabethan age,' together with many translations from the Italian, and much curious matter. In his Saggio di Contrappunto, he has given two madrigals, and then aaria da gamba, from the works of this celebrated master, all of them evincing his deep knowledge of the art, as understood and practised in his time, but all exclusively confined to that style now distinguished by his cognomen—by the term alta Palestrina.'

(Baini, Vita di G. P. da Palestrina; Burney, iii. 188; Horatianicus, x. 71.)

PALL. [SAMEY, LANGUAGE AND LITERATURE, F. C.]

PALICOURIEA, a genus of plants belonging to the natural order Cinchonacea. The limb of the calyx is 5-toothed or 5 lobed, or nearly entire; the corolla tubular and cymose, with deeply cleft limb, and a little hair beneath the base. The petals are white, and the corolla sometimes rather unequal. The species are American shrubs wholly destitute of pubescence. The leaves are often simple or 3 parted and of a saffron-coloured. The flowers are white in terminal sessile or stalked panicles, thyrses, or cysses. P. Marcropetali is a shrub from 5 to 6 feet high, and has smooth quadrangular branches. The leaves are short-stalked, oblong, acuminate, obsolete at the base, smooth; the stipules are deciduous and triquetrous. The calyx is 5-toothed and downy; the corolla from 5 to 7 lines long, slightly curved, gibbous at the base, roughly downy yellow-coloured below, purplish above, closely bearded with hairs inside. Sometimes the leaves are downy beneath. It is a poisonous plant, used in Brazil to kill rats and mice. Very little is known of its real properties.

P. crocra has a smooth stem, ovate or oval lanceolate leaves. The flowers are of a pink rose, often double, the petals arching over the base, side linear, acuminate, twice as long as the petiole. The panicle is corymbose, terminal, and suffron-coloured. The calyx is oblomical and tubular, the anthers projecting from the tube. The fruit is a globose capsule. It is an annual. It is natural to Porto Rico, Trinidad, Cuba, and Gra
daloupe. According to Von Marlies this species is evergreen. P. speciosa has smooth round branches, oblong acuminate leaves, an orange are ovate at the base, minutely pubescent, often double, the petals are stalked, their angular branches and corolla hairy and downy. The leaves have by their yellow colour obtained for the plant the name of Gold- shrub, highly prized in Brazil and the West Indies for decoction, which in large doses forms a real poison, acts especially by an increased action of the skin and kidneys, and the digestion is not injured by moderate doses." (Martius.)
404  

P. officinalis is a shrub clothed with harsh yellow down in every part. The leaves are narrow, elliptical, short-stalked, acute, or rounded at the apex with a mucron tapering a little at the base. The flowers hang in terminal panicles. It is native of Brazil, and is reported to be a powerful diuretic, and is used both in human and veterinary medicine. 

Other species of this genus are said to have qualities similar to P. officinalis, such as P. latifolia and P. longifolia, which are mentioned for possessing medicinal virtues. 

P. lactuca is a genus of plants belonging to the natural order Rhamnaceae. It has a spreading 5-cleft calyx, 5 obvolute convolute petals, 5 protruding stamens, ovate 2-celled anthers, and a flat pentagonal disk. The fruit is dry and indeshiscent, expanding in a membranous ring, containing a 3-celled nut. The species are shrubs or trees, with alternate simple leaves. 

P. aculeatus, Christ's Thorn, is a very common plant in Palestine, and on the borders of the Mediterranean Sea. It has pubescent horseless ovate serrated leaves, quite smooth, 3- or 4-cleft petaloid spines at their base, erect, more or less hooked. The flowers are of a greenish-yellow colour. The fruit has a very singular appearance, resembling a head with a broad-brimmed hat on: the French call the tree 'Fortin Chardon' from which it grows. There is a tradition that this is the plant from which the crown of thorns was made which was placed on the head of our Saviour. 

Bauhussiut is however of opinion that it was rather the Zizephus spinos Christi. This species of Paliurus is one of the most common thorns in the hedgerows of Asia, and its flexible spiny branches form an impassable kind of fence. The seeds are sold in the herb-shops of Constantinople, and the native doctors prescribe them in many complaints under the name of the Aegean. They are also used as a dye. There are two or three other species of this genus, which are handsome shrubs, and well fitted for shrubbery. They will grow in any common soil, and may be propagated either by layers, cuttings, or seed. 

(Don, Gardener's Dictionary; Burnett, Elements of Botany.) 

PALLADIUS, a Roman writer on agriculture, whose complete name is Palladius Rutillus Taurus Eumilianus. The place of his birth and his period are uncertain, but it is probable that he lived about the time of Valentinian and Theodosius. He is author of an extant work entitled 'De Re Rustica' in fourteen books. The first book contains general rules about agriculture; the twelve following books are respectively devoted to the agricultural labours of each month; the fourteenth book is an elegant verse treatise of grafting trees. The work of Palladius is the only one of this kind that was annotated by previous writers, such as Columella and Martianus Gargilius, whose work on agriculture and garden cultivation is lost. The 'De Re Rustica' of Palladius was an inspiration to a later work. The work of Palladius, probably owing in some degree to the convenience of the division, was much used in the middle ages, and the 'Speculum' of Vincent of Beauvais has borrowed much from it. 

Palladius and the other Roman writers on Agriculture are contained in the edition of the 'Scriptores Rei Rusticae' by J. M. Geiger, Leipzig, 1755, and in the improved edition of the same work by Ernesti, 1773. The latest edition and the best is by J. G. Schneider, Leipzig, 1794-7, 4 vols. 8vo. 

(Bubh, Geschichte der Romanschen Literatur.) 

PALMA, one of the Canaries, is situated between 28° 29' and 28° 56' north latitude, and 17° 39' to 27° 45' west longitude. From north to south it extends about 26 miles, and from east to west about 16 miles in the widest part. The average width is about 14 miles. This gives a surface of 364 square miles, corresponding to 554 square miles. 

The island is one mass of volcanic rocks. The shores are rocky and steep, and generally rise to a considerable elevation from the shore; the country rises in terraces towards the interior. The highest point of the island is in the middle of the northern portion of the island is an immense crater, the Caldera de Tahriuriente, which is seven miles in diameter; the bottom of it is 2406 feet above the sea-level. 

It is surrounded by steep masses of rocks, which rise 4000 feet above its bottom. In its vicinity are the highest summits of the island, the Pico, the Muchachos, which attains 7712 feet, the Pico de Sta. Cruz, which is 7649 feet, and the Pico del Cedro, which rises to 7292 feet above the sea-level. Further southward the mountains decrease in elevation. The Pico de la Lavanda, situated nearly in the centre of the island, is 4536 feet above the sea. Towards the southern extremity the heights are much lower. These rocky masses are split by very deep fissures, and broken bottom are frequently 500 feet below the adjacent masses, and the sides very steeple. They are most frequent in the high mountains which surround the Caldera, around which they are disposed in concentric rings. These rocky slides are often covered by a mixture with the crater, with the exception of the Baranca de Angustias, on the west side of the island, which originates in a crater itself, and descends to the sea, and in which the only river runs which has water all the year round. It waters the Las Llanos, an uneven plain situated on that side of the island which is the best portion of the whole, and at present contains the only plantations of sugar-cane in the Canaries. The sides of the mountains are very steep, and covered with high forest-trees that yield several kinds of good timber. This is especially the case in the northern districts, where the soil contains the moisture, and in these parts springs are frequent and abundant all the year round. In the southern districts the soil consists partly of lava or of other dry volcanic matter, and there are spots where they are cultivated with success, and where a great degree of fertility; but with the exception of the Llanos, the cultivated tracts occur only on the very shores of the sea, or at a few places on the lower terraces of the mountains. 

The climate of Palma is superior to that of the other Canaries in its neighbourhood. This is partly attributed to the extent of the mountains, which for several months are covered with snow, and give protection, which covers a considerable portion of its surface. The north-east trade-wind, which blows from spring to autumn with considerable force, diminishes the heat, which otherwise would be insupportable to the livestock. The rainy season is from January to May, and the dry season from June to December. The climate of the island, without the consideration of its southern parts, is so mild that it is compared with the spring in southern Europe. Earthquakes are not rare, and two volcanic eruptions in the southern districts, in 1586 and in 1678, are recorded. 

Palma resembles Teneriffe in its productions. Wheat, barley, rye, and potatoes are cultivated to some extent, and also a small quantity of Indian corn, but the crops are far from being sufficient for the consumption. The deficiency is made up by the root of a kind of fern, called helicco (Phrys aquilina), which grows wild on the small hills in the calderas. It is mixed with flour, or even used alone for making bread, which is especially good, and is said by Von Buch to constitute the principal article of food for two-thirds of the inhabitants. The cane is still grown in the Llanos, but the cultivation is much diminished, and some years ago it was said that the cane did not exceed 1000 tons. In the town of Havanna one plantation produced 30,000 arboles. It appears that more silk is produced in Palma than on any other of the Canaries. The vineyards are extensive, and wine is exported; the surplus is converted into brandy, which goes to the Spanish colonies in America. The fruit-trees which are found in the orchards are the same as those mentioned in Teneriffe, P.C., vol. xiv., p. 204. Few horses, mules, and asses are kept. Cattle are rather numerous, but neglected; sheep and goats are kept in great number, especially in the vicinity of the Caldera. The number of hogs is small. The population amounts to 20,878 individuals, but MacGregor states it in 1830 to have increased to 33,000. The people are descendants of Spaniards, who settled there at the time of the conquest, and of a few Flemish families. They are very industrious. The chief industry is the raising of poultry, and the raising of cereals. Many people live in straw huts, and subsist for two-thirds of the year on the black bread made of the helicco. But they are very industrious. In the Llanos there are 236 silk-rooms, in which silkworms, silkworms, silk ribs, and other parts of the work are done. They export some coarse cotton and Woolen cloth. In two or three places tiles and terracewar are made. 

Palma is not visited by foreign vessels. Some vessels from Teneriffe trade with the island, and deliver the ballast, consisting of sugar, almonds, fruits, deals and timber, pitch, charcoal, raw and manufactured silk, brandy, and orchilis. They import European goods, oil, grain and potatoes, saltfish and sugar. 

Palma has several ports: Epinolida, Santo Domingo,

picture restorer, who was the first to transfer frescoes from
the wall to canvas. The first work so transferred was the
Descent from the Cross by Daniele da Volterra, in the church
of Trinity do' Monti, in 1811 : it is still in this church, but
not in the chapel in which it was originally painted. The
successful transfer of this picture caused a great sensation at
Rome and in other parts of Italy, where such transfers were
and still are repeatedly practised with success : the process
Palmaroh transis described in the article Fbesco, P. C. S.
ferred and restored many celebrated works in Rome and in
Dresden, and among those in the latter city the celebrated
Madonna di San Sisto by Raphael was restored by him. Palmaroli has done great service as a restorer : he freed in 1 816 the
celebrated fresco of the Sibyls, painted by Raphael for Agostino
Chigi in the church of Santa Maria della Pace, from the destructive restorations in oil which were made by order of Alexander VII. Although some restorations were necessary and
are evident in this work, the lovers of art are highly indebted
to Palmaroli ; for, before his undertaking, this celebrated
fresco was a subject of general disappointment to the admirers
of Raphael, and was indeed so dark that the objects were
scarcely distinguishable.
He died at Rome in 1828.

PANVI'NIO, ONU'FRIO, was bom at Verona in 1529.
He took at an early age the habit of the order of St. Augustin, and pursued his studies at Rome, whence he was
called to Florence in 1554 to fill the chair of theology in
that city ; but soon afterwards, at his own request, was super-

seded in the office, and obtained leave from his superiors to
visit the chief cities of Italy in order to collect inscriptions.
At Venice he became acquainted with Sigonio, who had
been appointed professor of belles lettres in that city in 1552,
and who was not less enthusiastically attached than Panvinio
himself to the study of antiquities. The acquaintance soon
ripened into a lasting friendship. At Rome he was patronised
by Cardinal Cervini, who in 1555 became Pope Marcel us II.,
and by him Panvinio was appointed to a situation in the
library of the Vatican, with a salary of six gold ducats a
month. The pope however died a short time after his election ; and Panvinio was then patronised by Cardinal Farnese,
who gave him apartments in his palace, admitted him to his
table, and treated him in other respects with the greatest
liberality.
Having accompanied the Cardinal in a voyage to
Sicily, he was taken ill at Palermo, and died there April 7,
1568, at the age of thirty-nine.
Panvinio was a man of great learning and indefatigable
industry. Niceron, in his ' Memoires,' mentions twenty-seven
and Maffci, in his

P. qvxnquefotium, Five-leaved Panax, or Ginseng, has a
fusiform root more or less branched, of a whitish colour, and
terminating in fibres. The stem is smooth, round, and green,
often with a tinge of red, divided at the top into three petioles
with a flower-stalk in their centre. The petioles are round,
smooth, and swelling at their base. The leaves ternate,
quinate, or septenate.
The berries are kidney-shaped, of a
The
bright red colour, and contain 2 semicircular seeds.
It is a native of Chinese
flowers are of a yellowish colour.
Tartary and North America. In China it has been considered
an invaluable drug from time immemorial.
In 1709 the
Emperor of China commissioned 10,000 Tartars to go in
quest of as much of this root as they could find ; each one was
to give two jxmnds of the best of it to the emperor, and to
sell the rest for its own weight in fine silver.
The roots
enter into the composition of every Chinese medicine.
It is
reckoned a stimulant and restorative, and both rich and poor
consider it a remedy for every disease.
By Europeans and
Americans, however, it is comparatively disregarded, and
looked upon as a mere succulent, similar in its qualities to
liquorice ; hence the question arises, is the Chinese plant
the same as the North American ? For we cannot regard all
that the Chinese say and practise as merely imaginary.
The
common name of the plant, Gen-seng, Jinchen, or Nindsin,
'
signifies wonder of the world,' or the ' dose for immortality
and the Chinese firmly believe that its powers are almost
miraculous.

insect varies in size from less than an inch across the wings when expanded, to nearly a foot in breadth. Equally variable are their colouring and outlines. They are short-lived. Their powers of flight are very great, and the mode of flight varies in the several species. The males are usually more gaily coloured than the females.

The arrangement according to natural relations of the species of butterflies has been attempted by many naturalists. Even in the time of Linnaeus the number and variety of known species was such as to render it necessary to subdivide his great genus Papilio. He constituted five principal groups. In the first of these, named Eupides, he included such butterflies as have the fore wings longer from the posterior angle to the apex than to the base. In the second, the Heliconii, the wings are narrow, entire, and often almost naked. The Danaii had also about six species. The Nymphalids have the most powerful wings; and the group of Pierides was composed of small species, whose larvae are usually short and thick.

Dr. Horsfield has proposed an arrangement of these insects into five groups or strata, characterised by the peculiarities of the larvae. He names the first strata, Verniformes, the second Juliform, the third Scolopendriform, the fourth Thy- smomorpha, and the fifth Anthropomorpha.

Perhaps the most valuable arrangement of the diurnal Legadopera is that proposed by M. Boddard, who divides them into three great sections and fifteen tribes, as follows, founding his classification upon the characters of the larva:

Section 1. 

A. Six feet in both sexes: caterpillars elongated. Tribe 1. Papilionids.

4. Lycenidae.

C. The males with four feet, the females with six. Caterpillars short.

Tribe 5. Erycinae.

Section 2. Susexisi.

A. Unguis of tarsi simple. Four feet in both sexes. Tribe 7. Dasiidae.

B. Unguis of tarsi strongly bifid. Four feet in both sexes.

11. Morphiidae.

12. Satyrinae.

13. Erassolidae.

C. The males with four feet, the females with six. Caterpillars elongated.

Tribe 15. Napheidae.

See Boddard in the Novitates & Buffon and his other works; and Wood, Insect Entomologici; Horsfield, Catalogue of Lega- dopera in the Museum of the East India Company; and Westwood's Modern Classification of Insects, where an enumeration of the principal treatises on butterflies may be found.

PAPIRUS, SEXTUS or PUBLIUS, is the collector or supposed collector of the old Leges Curitae, or as they are sometimes called, Leges Regiae, which were enacted at Rome during the kings' time. This Pappirus is said to have been Pontific Maximus and to have lived under the last Tarquin. The few and doubtful fragments of this supposed compilation are contained in Hoffmann, Hist. Juris, vol. i. p. 1. The collection is mentioned under the name of Joa Papirunion, not because he added anything of his own, but because he arranged the laws in due order (Pomponius, Dig. 1, tit 2, s. 2, § 2); and sometimes it is called Lex Papiria. (Servius ad Virg. Aenid, 826.)

PAPIRUS, JUSTUS, a Roman jurist, who compiled twenty books of Constitutions, according to the Florentine Index. There are sixteen excerpts from this work in the Digest. In one of them (Dig. 14, tit 2, s. 50) Papirius mentions a rescript of the Emperor Antoninus, addressed to Avinius Cassius. The fact of the rescript being addressed to Cassius shows that Antonius is the Emperor Marcus Anto-

inus. Accordingly Papirius was living under Marcus Antoninus; and he also survived him, as appears from his speaking of the Divi Fratres. A jurist of the name of Papirio Fronto is cited by Cal- listratus (Dial. 14, cit. 3, s. 4.)

PAPIST. [ROMAN CATOLICHS, P. C. S.]

PAPAW. [CARICA, P. C.]

PAPALIS, B. DES, a genus of Trilobites, from the Silurian strata. (Brookman.)

PARAPET, in Fortification, is generally an embankment of earth which is formed either on the natural ground or on the upper surface of a fortress or outwork. In the latter case the parapet rests on that part of the rampart which is nearest to the exterior of the work, the terreplein, or nearly level part on the interior side, being occupied by the artillery. The majority of the modern parapets have the most powerful shape, and are constructed with stones or brick. Parapets of brick or stone are sometimes constructed for works which are masked by others in their front, or on heights, or on the seacoasts; but in other circumstances they would be improper, because the splinters detached from such materials by the enemy's shot are dangerous to the defenders, whereas the shot sinks into earth without doing further mischief.

The height of a parapet above the ground, or above the terreplein of a rampart which it surrounds, is about 7 feet, in order that it may effectually cover the defenders behind it. In its mass are cut the embrasures through which the guns are fired; the embrasures, or steps, about 3 feet high and 4 feet broad, is usually, of earth, at its foot, on the interior side, in order to enable men, by standing on it, to fire over the upper surface. The form of a transverse section of a rampart is represented in fig. 2, Barton, P.C. ; the parapet with its banquette being that which occupies, on the right hand side of the figure, rather less than the upper half of the space between the dotted lines.

The exterior face of a parapet of earth is generally formed in a plane making an angle of 45 degrees with the horizon, in order that the earth may stand unsupported; the superior surface, which varies in breadth from 3 feet to 20 feet according to the nature of the shot which it is intended to resist (from musket bullets to the balls discharged from the heaviest ordnance), has its exterior crest or edge lower than the other by about one-sixth of the breadth of that surface. It is recommended that the depression of the slope should not bear a greater proportion to the breadth, lest the upper part of the parapet should by its concavity be weakened; but the general rule is that the plane of the superior slope should, if produced, meet the counterscarp line of the ditch in front, in order that the enemy, at the time of an assault, and when detained by the obstacles there, may be completely exposed to the fire of the parapet. The interior face of the parapet, being a part of the parapet is frequently formed in a plane passing through the crest, and, at the terreplein of the banquette, or at the foot of the parapet if there is no banquette, deviating from a vertical plane at an angle of about one-twelfth of the height of the slope. By this inclination the earth, when revetted with fascines or sods, and even without any revetment, will support itself for a time, while a man, by leaning a little forward, is enabled without inconvenience to fire over the parapet.

Occasionally parapets of field-works have been formed with the earth obtained by excavating the ground in the interior; and, in this case, the crest of the parapet may be only 3 or 4 feet above the exterior ground. Such a construction is admissible, however, only when the site of the work is several feet higher than the ground which the enemy may occupy, since otherwise the defenders, except when close behind the parapet, would be exposed to his fire. Again, should the ground about the spot to be fortified be higher than that spot, the crest of the parapet must have a greater height than 7 feet, in order that the defences may be sufficiently covered by it; but in general the parapets of field-works cannot be raised more than 14 feet above the ground; since a man can scarcely throw earth with a spade to a greater height than 14 feet, and a greater height would require, above ground, more than two rows of shovellers, one row 7 feet above the others, and two rows, at an equal interval in the ditch; and it is seldom that the numerical strength of a working party is sufficient to allow such a disposition to be made.

The earth used for forming the parapets should be free from gravel, in order to avoid the accidents which might
from the dispersion of the stoners when shot or shells are fire; the slopes, as well as the banquets, are usually covered with turf.

PARASELENÉ (from σάρα and σαλάμινα the moon). This name is given to the ill-defined and faintly luminous disc seen in the sky by night, surrounding the moon, as the corresponding but brighter spots which are seen in haloes about the sun are called parhelia. [HALO, P. C. S.] The phenomena of parhelia and paraseleunés are ascribed to a like cause, a blending of the rays of light refracted from the parallel sides of small triangular plates of ice with those which are refracted through the sides containing one of the angles.

One of the earliest recorded phenomena of this kind is that which was observed by Hevelius at Danzig in 1660: a double halo surrounded the moon, with coloured segments nearly resembling those which are represented in the second figure in the article above referred to; and in the inner circle at each extremity of a horizontal diameter was a false moon; it was faintly tinged with colour and, at intervals, beams of whitish light proceeded from it towards the exterior.

Edward Alexandre, during his voyage to Melville Island, saw several lunar haloes with paraseleunés; and, once, very nearly the like phenomenon occurred on two successive nights. Two or more haloes to the halo at the opposite extremities of a horizontal diameter, and one at the upper extremity of a vertical diameter; while from the real moon proceeded vertical and horizontal branches of whitish light like a four armed star. It was one of the first records of light issued from the eastern moon, like part of a second halo, and at times ascending almost directly towards the zenith. At another time the moon was surrounded by a double halo, and on the circumference of the outermost, at the opposite extremities of a vertical and a horizontal diameter.

PARENT-DUCHATELET, ALEXANDRE-JEAN BAPTISTE, was born at Paris on the 20th of September, 1790. His father held an office under government which had been in the family for upward of three centuries. At the birth of Alexandre he was possessed of considerable wealth, but the changes and reverses of fortune had seriously affected his circumstances, and he retired to a house in the country called Chattelet, about a league from Montargis. Here Alexandre, who was the eldest of five, was brought up with little further assistance in his education than could be given by his mother, who was an amiable and accomplished woman. He was, however, fond of study, and early exhibited a taste for natural history by collecting the insects and birds of the neighbourhood.

At the age of seventeen he was sent to Paris, where he commenced the study of medicine. In 1814 he took the degree of doctor of medicine, but afterwards returned to Paris. He became early dissatisfied with the practice of medicine, and directed his attention to pathology. One of the earliest works which he published was upon inflammation of the kidney, which was not published at the time by M. Martinet; the title is "Recherches sur l'Inflammation de l'Arachnoïde cérébrale et spinale, ou Histoire théorique et pratique de l'Arachnoïde," Paris, 1821. This work is a valuable monograph. The mind of the author was however shortly after directed, through the influence of Hallé, to the subject of public health, and from the period that he first thought on this subject to the day of his death, he devoted all the energies of his mind to it. From 1821 to 1828 he published twenty-nine memoirs and papers on various questions relating to public health. One of his first efforts on this subject was a series of reports directed to discover the causes of a disease which had occurred on board a vessel which was conveying poudrette across the sea. Parent examined the manufacture of this substance, which consists of a mixture of two matters which have no eunomy of each other, as it is stated from the drains and sewers of Paris, and, being exposed to the sun and air, are allowed to dry. In this state it is used as a manure. It was the fermentation of this substance, its action on meat and fish with that had produced the disease, and Parent recommended that in future plater of Paris should be mixed with it, which prevented the recurrence of such catastrophes.

The most important sewers of Paris, entitled "Essai sur les Clouques ou Egoûts de la Ville de Paris, envisagées sous le Rapport de l'Hygience Publique et de la Topographie Médicale de cette Ville," Paris, 1824. Parent-Duchatelet here displayed the peculiar aptitude of his mind for the investigation of subjects which others regard with natural abhorrence. He not only made it the study of the health of the workmen employed in cleansing these places, and obtained from them much important information, but he entered with them the places of their noisome occupation, and, frequenting them, and surrounding the moon, as the corresponding but brighter spots which are seen in haloes about the sun are called parhelia. [HALO, P. C. S.] The phenomena of parhelia and paraseleunés are ascribed to a like cause, a blending of the rays of light refracted from the parallel sides of small triangular plates of ice with those which are refracted through the sides containing one of the angles.

One of the earliest recorded phenomena of this kind is that which was observed by Hevelius at Danzig in 1660: a double halo surrounded the moon, with coloured segments nearly resembling those which are represented in the second figure in the article above referred to; and in the inner circle at each extremity of a horizontal diameter was a false moon; it was faintly tinged with colour and, at intervals, beams of whitish light proceeded from it towards the exterior.

Edward Alexandre, during his voyage to Melville Island, saw several lunar haloes with paraseleunés; and, once, very nearly the like phenomenon occurred on two successive nights. Two or more haloes to the halo at the opposite extremities of a horizontal diameter, and one at the upper extremity of a vertical diameter; while from the real moon proceeded vertical and horizontal branches of whitish light like a four armed star. It was one of the first records of light issued from the eastern moon, like part of a second halo, and at times ascending almost directly towards the zenith. At another time the moon was surrounded by a double halo, and on the circumference of the outermost, at the opposite extremities of a vertical and a horizontal diameter.

PARENT-DUCHATELET, ALEXANDRE-JEAN BAPTISTE, was born at Paris on the 20th of September, 1790. His father held an office under government which had been in the family for upward of three centuries. At the birth of Alexandre he was possessed of considerable wealth, but the changes and reverses of fortune had seriously affected his circumstances, and he retired to a house in the country called Chattelet, about a league from Montargis. Here Alexandre, who was the eldest of five, was brought up with little further assistance in his education than could be given by his mother, who was an amiable and accomplished woman. He was, however, fond of study, and early exhibited a taste for natural history by collecting the insects and birds of the neighbourhood.

At the age of seventeen he was sent to Paris, where he commenced the study of medicine. In 1814 he took the degree of doctor of medicine, but afterwards returned to Paris. He became early dissatisfied with the practice of medicine, and directed his attention to pathology. One of the earliest works which he published was upon inflammation of the kidney, which was not published at the time by M. Martinet; the title is "Recherches sur l'Inflammation de l'Arachnoïde cérébrale et spinale, ou Histoire théorique et pratique de l'Arachnoïde," Paris, 1821. This work is a valuable monograph. The mind of the author was however shortly after directed, through the influence of Hallé, to the subject of public health, and from the period that he first thought on this subject to the day of his death, he devoted all the energies of his mind to it. From 1821 to 1828 he published twenty-nine memoirs and papers on various questions relating to public health. One of his first efforts on this subject was a series of reports directed to discover the causes of a disease which had occurred on board a vessel which was conveying poudrette across the sea. Parent examined the manufacture of this substance, which consists of a mixture of two matters which have no eunomy of each other, as it is stated from the drains and sewers of Paris, and, being exposed to the sun and air, are allowed to dry. In this state it is used as a manure. It was the fermentation of this substance, its action on meat and fish with that had produced the disease, and Parent recommended that in future plater of Paris should be mixed with it, which prevented the recurrence of such catastrophes.

The most important sewers of Paris, entitled "Essai sur les Clouques ou Egoûts de la Ville de Paris, envisagées sous le Rapport de l'Hygience Publique et de la Topographie Médicale de cette Ville," Paris, 1824. Parent-Duchatelet here displayed the peculiar aptitude of his
scales yellow. It is native throughout Europe, in marshy and wooded places, in Britain and many countries. *D. fimbriata* is a very elegant species; the leaves are remarkably hallowed out at the base close to the lateral ribs, which are connected with one another by a common base like the segments of the leaf. It is also used for birds' ornaments, oblong petals fringed at the base. It is native of the western coast of North America.

The species of this beautiful genus grow best in a moist soil and in pots. They must be watered, but not fertilized, since the florets are placed in water. They may be propagated by dividing at the root, or by seeds, which ripen in plenty. Plants must be introduced, as seeds do not vegetate after a few weeks. (Don's Gardener's Dictionary; Babington, Manual of British Botany.)

PARNY, EVAIRISTE DESIRE' DESFORGES, Chevalier and afterwards Vicomte de Parny, was born in the Isle of Bourbon, on the 6th of February, 1753. At the age of nine he was sent to France and placed at the College of Kennes; but he appears to have shown considerable indifference to the course of studies which were followed there. His imagination, which even at an early age had taken the almost entire guidance of his conduct, impressed him as he grew up with the belief that he was called upon to embrace the profession of a priest, and it is said that he attempted to join the brotherhood of La Trappe. An effort of imprudent zeal, however, on the part of the confessor whom he had chosen as his spiritual guide, produced a rapid change in the mind of the young Parny, and he became resolved to have himself intrusted into an opposite extreme of conduct, and soon after, entering into all the dissipations of youth, finally to have enrolled himself in the military profession. He returned to his native island in the age of twenty, where he became acquainted with a young creole lady, the Eleanor of his verse, which acquaintance his fervent imagination soon converted into the most ardent attachment. Their mutual love inspired his first poetical efforts, which paint with grace and freshness, though perhaps in too vivid colours, the all-absorbing passion of his soul. The affections however of the lady were of an express nature; for a marriage of interest, which she induced to be acted at the desire of her parents, induced Parny to return to France. Distance and time were unable to efface his real remembrances, and he there continued to translate into the language of poetry the feelings which appear to have taken a lasting possession of his mind. In 1775 was published his first collection of elegiac poems, which have been so much admired by his countrymen that they have earned for him the title of the French Tibullus. On the breaking out of the French Revolution he became deprived of the property which he had inherited from his father, and he was compelled to obtain a livelihood by the cultivation of his talents. A painful and slender income now appears to have been to him a blessing, for it had the weakness to adapt to the prevalent taste of a corrupt age. The rival of Tibullus became the feebler copyist of Voltaire, and his 'Paradis perdus,' and 'Galanteries de la Bâtie,' and 'Retour du voyageur,' are mere imitations. By their disavowal of genuine poetic feeling, only will be remembered by posterity as indications of the state of society at a period when 'everything evil was rank and luxuriant.' So strong indeed was the feeling excited against Parny even in France on account of the last mentioned of these three poems, that his name was repeatedly passed over among the candidates for the honours of the Institute. However, he was admitted into it in 1803, in the place of Devaine. Most of his other poems are inferior to his early productions; his 'Goddam,' published in 1804, is a spirited and inspired parody on the invasion of England by the Norman, his 'Imad and Asilda,' though possessed of more merit, is but a feeble imitation of the Scandinavian style of poetry; but among his later productions there are two small poems, one on the culture of flowers, and the other entitled 'Joumée Champêtre,' which for simple beauty and delicacy of colouring are deserving of being ranked among the finest specimens of lyric poetry. His principal poem, in eighteen cantos, on the lives of the heroes of Greece, was destroyed by falling into the hands of the suspicious judges of the Revolutionary Tribunal. He died in Paris, after a painful and lingering illness, on 6th December, 1814.

His works were published in 1806, by Didot, Paris, 1808, and at Brussels, in 2 vols. 8vo. The best edition, however, is that by Mons. Boissonneaud in the 'Collection de Classiques Français,' Leuver, Paris, 1827. A volume was published in 1826 entitled 'Poesies inédite de Parny,' with a notice on his life and writings by Mons. Thos.

PAROCHIAL REGISTERS. [Registration of Births, &c., P. C. S.]

PARS. [French, P. C. S.]

PARTNERSHIP. In 1857 a statute was passed (7 Wm. IV. & 1 Vict. c. 73) authorizing the crown, after a reference of an application to the Board of Trade, to grant a species of incorporation to trading firms, known as 'Companies Limited by Guarantee.' The patent may limit the responsibility of partners to a certain sum per share. The company obtaining such a privilege must be constituted by deed of partnership, containing its name, the limits of its powers and the names of the members, and the appointment of two officers in whose name the company may sue and be sued. These matters must also be entered, along with the additions of the members and the shares held by each, in a numerical order in which must be made within three months of the date of the patent—in England or Ireland, to the Registrar Office of Chancery; in Scotland, to the General Register House. Notice of the same must be sent within three months. This registration is the criterion both of benefits and responsibilities: no one is entitled to profits unless as securing to registered shares, and no one is relieved from responsibility unless as receiving the benefit of the patent. The extent to which this statute may have been adopted in practice is not publicly known.

PASSAU. [Building-Act, P. C. S.]

PASTA, long-haired seeds of fossil fish from the Baghad sand. (Buckland.)

PASSENGERS. [N.P. C.]

PASSENI, GIOVANNI BATTISTA, a distinguished painter of portraits, was born in 1702. Collections of biographies of Italian artists, was born at Rome about the year 1610 or earlier. Passeri received a good education, and, according to his own account, did not take up painting until comparatively late; he was first engaged in the vocation of a painter in 1636 by Canini in the Villa Aldobrandini at Frascati, where he contracted an intimate friendship with Domenichino, then in a state of decay, and on returning to Rome in 1641, Passeri was president of the Academy of St. Luke, and he read a funeral oration on him, and painted a portrait of him, which was placed in the academy with other portraits of painters, which are at present in the gallery degli Uffizi at Florence; the portraits now in the academy at Rome are copies. (Platner, Beschreibung der Stadt Rom.) At the close of his life Passeri entered into holy orders; and obtained in 1672 a benefice in the college of Santa Maria in Via Lata. He died in 1679.

Passeri is one of the best of the Italian historians of art; his theoretical knowledge was good and his facts are believed to be correct. He was known in his time for being a bit of a rival for nearly a century unnoticed, or rather unpublished, owing to its unfinished state and the want of many of his remarks, especially on Bernini. It was first published in Rome by an anonymous editor, under the title 'Le Passeggi per la Tradizione della Pittoriche' in 1772, with some omissions, under the title 'Vita de' Pintori, Scultori, ed Architetti che anno lavorato in Roma, morti dal 1641 fino al 1787,' by Giambattista Passeri, Pietro Testa, Giuseppe BtschreUnmg, Gio. Ang. Canini, Guercino, B. Borsini, M. F. Mols, Pietro da Cortona, and Salvator Rosa. There is only one public picture by Passeri in Rome, a crucifix which is preserved in the church of San Giovanni della Maia. They are not so rare in galleries. He painted sometimes still-life. His nephew Guiseppe Passeri was likewise a good portrait painter. He died in 1733, aged sixty.

PASQUALINO, DOMENICO D. Michieli been born in 1550, but died in 1611. His picture called Caspari, Cavaliere, was born at Florence about the middle of the sixteenth century. Some accounts give 1560, but this is probably too late. Baglione says he was eighty years old.
when he died in 1638, which would place his birth in 1657 or 1658. He was the pupil of Federigo Zuccaro, and lived some time in Venice, where he acquired a great preference for the Venetian school of painting, and especially the works of Paolo Veronese.

In 1625, having been elected as a pupil of the Academia di Belle Arti, he was employed by the popes Paul V. and Urban VIII. ; he painted the Crucifixion of St. Peter for the Capella Clementina in the great church of St. Peter on the Vatican, for which he was paid 1500 ducats. In 1638, he spent the latter part of his life at Florence, and he was one of the most influential of those painters who contributed towards the reform of the Florentine school by improving the taste for painting derived from the schools in the Low Countries. Passignano was the friend and associate of Cigoli, and is said to have been the master of Lodovico Caracci, who died in 1638. He had many scholars, of whom Pietro Sorci of Siena was the most distinguished.

(Baglione, Vita dei Pittori, &c., Lani, Storia Pictorica.)

PASTINA/CA (from pastinum, the Latin name for a two-pronged fork), a genus of plants belonging to the natural order Umbelliferae, and the tribe Paeonieae. It has a calyx 5 very small or nearly obsolete teeth; round entire petals, involute, with an acute point. The fruit has a dilated flat margin. The ceps with slender ridges, 3 dorsal equidistant, 2 lateral ones near the margin of the dilated margin. The umbrellas with single linear vittae.

P. sericea, Parnep, has an angular furrowed stem, pinnate leaves, downy beneath, ovate oblong leaflets, crenate, serrate, or entire. It has the same flowers as P. officinalis, not more than 2 feet high. The flowers are yellow. The leaves generally appear before, sometimes downy beneath. It is native of Great Britain and of Europe, even to the Caucasus, on hillocks and sand-dunes; in some places it becomes a thicket of light white, aromatic, mucilaginous, and has a sweet taste. A variety of this species, P. adusta, is the common edible parnep, and is much cultivated in our gardens. For cultivation and uses see P. officinalis.

Another variety, called P. Coquinea, has roots from three to four feet long, and upwards of six inches in circumference. It is extensively cultivated in Jersey and Guernsey as fodder for cattle, and is also planted as a common hedge. It is the characteristic kind of a kind of beer brewed with hops. Wine and as a spirit are likewise made from the roots.

P. Sekukul is another edible species of this genus, and is native of Syria and of Egypt. It has a grey root, a terete downy branched stem, pinnate downy leaves, pinnatifid cleft leaflets, blunt and unequally toothed. It is cultivated in the Levant, under the name of Sekaku.

The species are only to be increased by seed, which should be sown in the open border early in the spring.

(Do.

Don't Gardner's Dictionary; Babington's Manual of British and Foreign Oils, etc.; Babington's Oildom.)

PASTURE, COMMON OF. [COMMONS, P. C.]

PATELOUDEA, a genus of Moluccas proposed by MM. Quoy and Gaimard for certain Gasteropoda, which have a single lid and are limpet-like. The animals are cervice-brancheat. It is synonymous with the genus Lottia of J. E. Gray. The Patella testudinaria of Otbo Fabriuseus, a shell not uncommon on the northern coasts of Britain, is the type. Numerous species are known, inhabiting all latitudes and living in various depths of water. Their shells are gaily coloured, often tessellated and rayed with purple, orange, or pink. The animals are usually of a uniform tint of white, orange, or pale red.

PATENT. The 7 & 8 Vict. c. 69, § 2, enables a patentee, by petition to the Queen in council, to obtain an extension of the patent term for any time not exceeding fourteen years, 'subject to the condition that he shall have paid for the said extension seven years, is now granted under the powers of the said act of his late Majesty (5 & 6 Wm. IV. c. 83).'

This act of Victoria contains also a provision applicable to the period mentioned in the above act. This was created in 1786, and forms the new letters-patent which may have been granted under 5 & 6 Wm. IV. c. 83, to an assignee or assignees, and declares that such new letters-patent shall be as valid as if they had been made new and original. It is clear that nothing in the said act contained shall give validity to any letters-patent heretofore granted to an assignee or assignees, when any action or proceeding in Suire facies or suit in equity shall have been commenced before the passing of this act, whereas the validity of such letters-patent shall have been or may be questioned.

PATENT. [PARTNERSHIP, P. C. S.]

PATERNITY, WILLIAM. Of the early history of this man, who originated several celebrated projects, little is known. By some accounts he is said to have brought a design up to the clergy of England, to have incorporated the West Indies, and to have subsequently become a buccaneer. In the account however of the parish of Tinwald, Dumfriesshire, in the first volume of the old statistical account of Scotland, it is stated that in 1660, he declared that in that parish about the year 1660, that he was respectively connected, and that he had more than once sat for Dumfriesshire in the parliament of Scotland. Whatever may be his early history, he must have had ample opportunities of making himself saumipacit and commerce and institutions of foreign countries, and he was probably an extensive traveller. His schemes regarding banking and trading projects are said to have been first offered to the mercantile communities in the Low Countries, and to have been coldly received. He subsequently laid his plans before the merchants of London, and it seems to be nowhere doubted that they were the foundation of the Bank of England, incorporated in 1694. (BANK, P. C.) From the rapidity with which the scheme was brought into a working shape, it may be conjectured that very little alteration was made on the original plan. It is a natural inference from the interposition of Pedro P. as a means of making the Bank for any length of time practically connected with the working of the institution. It is usually said that the rich capitalists, once possessed of his ideas, quarrelled with him, set him adrift, and engaged a bankrupt in his stead to its advantage. It is probable however that Paterson, though so able a sh e m e r , was a bad practical man of business; that his invention was perverted on the wing, and that he could not settle down to the routine of business with much advantage to either himself or to others. His next project, if it was not conceived at the same time as that of the Bank, was the renowned Darien expedition. Scotland was at that time filled with speculators, but in this, which was the most adventurous of all, the government under one crown, had lost much of that department of foreign service which their ancestors had held in states at war with England. There was an earnest desire to rival England in commerce and manufactures, and in colonies, of which Scotland was not previously possessed. An act of the Scottish parliament was passed on 26th June, 1695, incorporating certain persons by name, of whom Paterson was one, with powers to sell their number, to be called 'The Company of Scotland trading to Africa and the Indies.' Very important privileges, both in connection with foreign trade and with the institutions of the country, were conferred on the members. The company raised a large sum of money in England. Its progress roused the English jealousy of trade, and after some representations by the East India Company and other bodies, with houses of parliament presented an address to King William, in which it was complained on the ground of the superior advantages granted to the Scottish East India Company, and the duties imposed upon the Indian trade in England, a great part of the stock of shipping of this nation would be carried thither, by which means Scotland would be rendered a free port, and Europe from thence supplied with the products of the East much cheaper than through them, and thus a great article in the balance of foreign commerce would be lost to England, to the prejudice of the national navigation and the royal revenue. In fact, under the guise of a company having a monopoly, Paterson's plan would have developed itself in such a manner as a nucleus of free trade; and its opponents rather fell how unable they would be to compete with this untrammeled community, than saw in its constitution any general principle of the superiority to himself of what were to be left to them. They were connected. We do hereby publish and declare, says the first proclamation of the company, that all manner of persons, of what nation or people soever, and are shall have the benefit of the said act from henceforth, and shall enjoy all the said properties, privileges, protections, and immunities, and rights of government granted unto us; and the merchants and merchant-ships of all nations may freely come to trade with us without being liable to the punishment in any manner of capture, confiscation, seizure, forfeiture, attachment, arrest, restraint, or prohibition, for or by reason of any embargo, breach of the peace, letter of marque, or reprisals, P. C. S., No. 197.

VOL. II.—3 G
declaration of war with any foreign prince, potentate, or state, or upon any other account or pretence whatsoever. And we hereby not only grant, concede, and declare a general and equal restoration of all private, public, and national rights of all nations; and to all persons, and to all persons and states, who shall be hereafter to be of or concerned with us, but also a full and free liberty of conscience in matters of religion. In contemplation of a company carried on on such principles, the 'English partizans' were entertained and promised to be furnished with 'the privileges granted their company would render the country the general storehouse for tobacco, sugar, cotton, hides, and timber; the low rates at which they would be able to purchase all the manufactures of the Dutch, for the English to compete with them.' King William was induced to discontinue the undertaking, and the projectors were deprived of all aid, not only from England, but from foreign countries; yet this only made them more the national object, and all the disposable wealth of Scotland was speedily embarked in it. The main scheme of the company was to establish a colony at Darien, when Paterson believed that it would be in the middle of the highway of the world, and form the emporium where the commerce of the East would meet that of the West. With all due respect for the principles on which the company was to be conducted, it may be questioned if the place possessed all the peculiar advantages of which it had been made the object, especially at a time when regular commercial enterprise had made so comparatively little progress on the globe. The expedition set out on the 5th of June, 1698; but Paterson never returned to the period of the most ordinary histories of the period, and particularly in Sir John Dalrymple's Memoirs. Paterson was ambitious, but not mercurial, and in the palmy days of the company he had resigned the charge of it to a person of his own acquaintance, with intent to his benefit. The failure of the expedition preyed deeply on his spirits, and grief and disappointment brought him, during his return from the mission, to the borders of lunacy. He lived subsequently a life of obscurity and the period of his death is not recorded.

Patriarchs. We propose to give a chronological list of the Patriarchs of Alexandria, Antioch, Constantinople, and Jerusalem, arranged systematically with the Roman Popes, for which reason we place the article under Roman Caesars.

Pavonia (in honour of Don Joseph Pavon, M.D., of Madrid, a traveller in Peru; and one of the authors of 'Flora Peruviana'), a genus of plants belonging to the natural order Malvaceae. It has a 5-lobed persistent calyx, surrounded by an involucre of 6 to 15 leaves. The ovary has 5, and rarely 4, 1-ovuled cells. It has 10 stigmas, 5 carpels, capular, 2-valved, and 1-seeded.

P. diuretica has coriaceous serrated leaves, velvety on both sides, and full of pellucid dots. The flowers are large, yellow, and staminal. It is native of Brazil, in the province of Minas Geraes. A decoction of this plant is used in Brazil as a diuretic. This is the only species of Pavonia used in medicine; many others are however wild flowers, and are abundant in the woods. They are free-growing plants, for the most part ripening seed in abundance, and cuttings will root freely under a hand-glass.

(Don's Gardener's Dictionary; Lindley's Flora Medica.)

Pedicularis is a large genus of plants which is placed under another different accounts, and makes a payment of any one of such sums, he may state at the time of payment on which account such sum is paid, and the payment will be considered to be legally appropriated to the debt which he has named. If at the time of payment the debtor makes no appropriation of the payment, the creditor may at the time of payment appropriate it to such debt as he pleases, provided he applies it to the payment of the said debt, it shall be presumed that he would do, if he were the debtor. Accordingly the creditor must appropriate the payment to such debt as is the most burdensome to the debtor. If neither party makes any appropriation of the payment, the payment will be presumed to be made on account of the more burdensome debt; if there is no difference in the quality of the debts, the payment must be presumed to be made on account of the oldest.

These are the rules of the Roman Law (Dig. 46, tit. 3), which perhaps may be considered to be adopted by the English Law, though the decisions are by no means uniform in the application of its principles. In Noble, 1, 162, 926, the parties just laid down apply to distinct debts on different accounts (cause). If there are dealings between two persons which are all of one uniform and continuous nature, as for instance between a banker and his customer, there is no question of appropriation of payment. The customer pays money into the bank at different times, and draws it out by drafts at different times. All the sums paid in and all the sums paid by the bank and remitted to him are to be considered a single account, and by striking the balance at any given time it will appear what sum is due at that time from the banker to his customer or from the customer to his banker. It is true that this would be the case under the English law; but there is a kind that which is meant by the term. It assumes that the sum first paid in is discharged by the sum first paid out, so far as it is sufficient to discharge it; and the same remark applies to the account at the sum and sums drawn out. The account therefore must be made out in the order of time, and the balance will show how the account stands at the time when it is made out. (Devaynes v. Noble.)

There are various cases in the reports in which the question of appropriation of payments has been discussed. (Boddenham and Purchas, 2 B. and Ald. 39, Simpson and Ingham, 2 B. and Cr. 65; Pemberton and Oakes, 4 Russ. 164; and others.)

Pear-gage. The principle of Smear's pear-gage, for measuring the exhaustion of a receiver, differs from that of the other gages, in that the measurement does not take place until after the air has been re-admitted into the receiver. Suppose a wire working through a collar in the top of the receiver and supporting a tube open only at the lower end. Under the tube is a cup of mercury, and a receiver for the residue of the barium. A wire is placed so as to make the wire open the end of the tube may be immered in the mercury. The exhaustion being made before lowering the wire, the air in the tube will be rared equal to that in the receiver. As the wire is lowered, the receiver is admitted to the tube, the mercury will rise in the tube until the elastic force of the compressed air in the tube, together with the column of mercury, counterbalances the pressure of the external air. A gage attached to the tube shows, by the height of the mercury, what was the original rarefaction.

Now it is plain that while the ordinary gages show the actual amount of elastic force left in the receiver, the pear-gage submits the air, or whatever else there may be, to a process of compression before the measurement is made. If there be nothing but air, all the gages agree; but if, as generally is the case, there be also vapour, the pear-gage submits and much higher degree of apparent exhaustion than the ordinary gage. For further detail see the article 'Pneumatics' in the Encyclopedia Metropolitana.

Peculiaris, Court of, is one of the English ecclesiastical courts, or in the province of Canterbury, the other two being the Court of Arches, or supreme court of appeal, and the Prerogative or Testamentary Court. The Court of Peculiars takes cognizance of all cases in matters ecclesiastical within the archbishopric of Canterbury, or within the diocese of London, another in the diocese of Rochester, another in the diocese of Winchester, each comprising several parishes; and some others over which the archbishop exercises a general supervision, but not of any of the parishes of which it is independent of the jurisdiction of the several bishops within whose dioceses they are locally situated. (Political Dictionary, article 'Ecclesiastical Courts.')

Pedicellaris (from the Latin word pedicellus, a louse, from its supposed quality of making sheep that feed upon it lousy), a genus of plants belonging to the natural order Scrophulaceae. It has an inflated 6-toothed calyx, a ringed corolla, with the upper petals fused, and the lower petals plano 3-lobed. The capsules are acute, and compressed. The seeds numerous and angular. The species are usually simple herbs. The flowers sessile, disposed in dense terminal corymbi.

P. palustris has a solitary erect stem, branched throughout, pinnatifid leaves, with oblong blunt lobed segments; an ovate subsessile 2-lobed calyx, the lobes incisus, dentate, crisped. The upper petals of corolla has a small triangular tooth on each side. The flower is large and crimson, varying to white. It is found in marshes and wet meadows, particularly in the north of England, and is said to be injurious. It is the type of Pedicellaris Herba of Columella. 60, and of Scrophularia Lurges, P. gynacina has a stem branched at the base, erect, the branches long, spreading, and prostrate; the leaves pinnatifid, loblets ovate and deeply toothed. The upper lip of the
corolla as in the last species, the flower large and rose-coloured. It is found on wet, moist, and rather lightly grounds in Europe, and Great Britain. The expressed juice of the herb, or a decoction, has been used with advantage as an injection in serious ills. It is injurious to the sheep that feed on it. There are 75 other species of Pediu-

colony, Queen Isabella, the Queen of the Portuguese colony in Brazil, the Banda Oriental, the inhabitants of which were devious of annexing themselves to the new empire, and a war was the result, which terminated unfavourable to the independence of Brazil. To this cause of discontent another was added by the death of John VI. in March, 1826, and the consequent succession of Don Pedro to the crown of Portugal. This event excited the patriotic spirit in the Brazilians, and they declared himself of the kingdom which descended to him by hereditary right to the empire at whose head he had been placed by the will of the people, and thus Brazil should again become reduced to the position of a confounded Portuguese colony. Never however he endeavoured to dispel by abdicating the crown of Portugal in favour of his daughter Donna Maria da Gloria, respecting to himself the regency, with the title of king, during her minority. The instability of popular government has resulted from continual disturbances of a political nature throughout the country.

In 1830 the French revolution gave a new impulse to the democratic party, and an affray which took place on the 8th of April, 1831, the details of which are given in the article Brazil, P. C., determined Don Pedro upon abdicating the throne in favour of his son, to whom, being under age, he appointed a guardian, and the following day he left the country.

The throne of Portugal, which Don Pedro had resigned in favour of Donna Maria, had been usurped by his brother Don Miguel, whom in 1822 he had appointed regent of the kingdom. His object was to send the country from the usurper, and to reinsate his daughter in the rights of which she had been deprived. The plan of the enterprise was matured during a somewhat long residence the emperor had in Paris, where he was retained by his daughter, Queen Maria, who had espoused his cause, at the head of whom was General Baldanha, and a great number of foreign adventurers. For the details of the civil war which ensued we must again refer to another part of the Cyclopaedia. (Portugal, P. C.)

On the 26th of May, 1832, Don Miguel was reduced to the necessity of signing a convention, which left the young queen in quiet possession of the throne of Portugal under the regency of Don Pedro.

His acts of short administration were calculated to secure for him the good will of the more liberal party in his dominions; but many of them, though they had been expedient, were certainly unjust. He strengthened the external relations of Portugal by a close alliance with England and France, and in order to give an interest to the people in the new revolution he conferred for the use of the state the property of the numerous masonic establishments in his kingdom. The anathemas of the Vatican were the natural result of these sweeping measures, and they were soon followed by the death of his own excomunication. In Spain, they also designed for it a new system of government by dividing it into provincial administrations. The prince regent, sensible of the impolicy and injustice of this scheme, placed himself under the interposition of his delicious state of health compelled him to resign the regency, and his daughter, having been declared of age, was placed in full possession of the royal authority. He did not long survive to see the event. He died in 1834, and left the palace where he had been born the scene of his death on the 24th of September, 1834.

The life of Don Pedro is chiefly interesting as it connected with the general history of the period; the details of circumstances in which he was placed deprived him of the opportunity of putting into effect many measures of utility which he had the talent to design, and on a more quiet theatre he might have acted the part of a greater king.

Peel (or Peele), as the name is found in most books printed forty years ago, Sir Robert, the first baronet, was born 26th April, 1760, at Peel's Cross, near Lancaster, a small property belonging to his father, Mr. Robert Peel, whose third son he was. The family, though not wealthy, appeared to have been of some respectability for several generations. It is said to have been lately traced back to the sixteenth century. Sir Robert Peel's mother was the daughter of a clergyman of the Established Church; but the common accounts go no higher than to the great-grandfather of the subject of the present notice. He was a gentleman of the name of Backburn, Gentleman, and had a numerous family of sons. It is understood that the Peels had been Unitarians for some generations, and that Sir Robert was brought up in that tenet. When he was a young man he went to sea. It is said that he early gave evidence both of remarkable business talents, and of a decided ambition and determination to raise himself.
in the world. He and most of his brothers were brought up to different branches of the cotton-trade, now fast extending under the effect of the inventions of Arkwright, whose personal success in the acquisition of wealth and station was also of course operating as a powerful example and incentive. The mechanical processes of the trade are said to have made engaged much of Peel's attention, though they were never inclined to him for any improvement, so far as we are aware. He made his fortune by his general ingenuity and sagacity, by his great activity and intensity of mind, and by his considerable boldness of enterprise, and by his admirable conduct of business, alike in its largest scope and in its minutest details.

In 1799 Mr. Robert Peel entered into partnership with Mr. William Bury, of Nottingham, and became a member of that important and respectable body of members of Parliament, who, in the next session, in the session of 1810, 60,000,000. of their he 2, the 1584, 'was Comus. The capital.

corroboration is afforded by the play itself. Thomas Campbell, in his 'Specimens,' has spoken of Peele more favourably than any other critic. There is more of justice in the cool estime of his merits formed by Mr. Dyce and others. 'Those of the Essene order,' says Mr. Knight, 'afford evidence that he possessed great flexibility and rhetorical power, without much invention, with very little discrimination of character, and with that tendency to extravagance in the management of his incidents which exhibits small acquaintance with the higher principles of the dramatic art.' His inferiority to Marlowe is great and unquestioned; and perhaps it is only his musical though monotonous versification which has preserved for him a reputation without keys. They were found to be important communications, some in French for the court of Turin, and some in Italian for the court of Naples. Torey, then minister for foreign affairs, sooner or later would have procured an appointment for him in the French Academy but for the rupture between France and Britain, and the latter had some time been employed in the service of the French admiral of Naples, M. de Pellerin, a commissioner of the navy (commissionnaire de la marine) in 1718, and sent him on service to the great harbours of France, and in 1723 he was destined to make a general inspection of all the harbours, but a change of ministry took place, the council of the navy was suppressed, and other measures were decided on. Pellerin however still continued attached to the department of the minister for foreign affairs, and he was appointed minister commissioner general, and afterwards was made first clerk of the navy (premier commissaire de la marine), in which office his activity, probity, and firmness, combined with the sway of his manners, met with universal approbation. In 1745 bodily infirmities compelled him to retire from the public service. His son, who had served in the navy and in the naval department of the government, succeeded him in his office.

Pellerin, during his long service of about forty years, had used the opportunities which his situations afforded him in the collection of a considerable number of coins and medals, at first from curiosity, but afterwards from a taste for them, as muniments of his profession. He applied himself to the study of inscriptions, after his retirement, he began to read, explain, classify, and arrange them. His early studies in the oriental languages, as well as in Latin and Greek, were renewed, and became a source of particular profit to him in behalf of that magnificent collection of coins and medals which he formed in the course of the subsequent forty years of his life. He died at Paris, August 80, 1784, in his ninety-sixth year.

In the arrangement and classification of his medals Pellerin adopted a system different from that of any previous collector. Instead of distributing them in drawers according to difference of metals, and arranging them alphabetically without reference to the countries to which they belonged, he placed them according to certain geographical divisions, preserving however an alphabetical arrangement of the medals of kings, nations, and tribes, which divided the division of nations. His descriptions of the medals, with his comments and remarks, formed a large Catalogue raisonné, which he published under the title of 'Recueil de Médailles de Rois, Princes et Benefacteurs de France,' in 1719. His delight in his favourite study was such that when upwards of ninety years of age and blind, he composed and wrote with his own hand, by means of an ingenious contrivance, the last volume of this work, which was finished in the year 1770.

Peeter, in his 'Doctrina Numorum Veterum.' [Ecつき, P. C.] Pellerin and Ecつき were both friends of the great savant, and in 1767 he subjoined to the former, his beautiful collection of medals, which consisted of 23,500 medals, was bought by the King of France, in 1776, for 300,000 francs. The king afterwards allowed it, as long as he lived, the use of the whole of the royal collection, which then amounted to about 44,000. The most important additions which have since been made to numismatics relate to the coins of the kings of Bactria. [Prissis, James, P. C.; Afghanistan, P. C. S.]
dable value in the diocese of Auch. However, he is favourably distinguished from most prosectys by the lenient and tolerant disposition which he evinced towards those who disagreed with him in opinion, and when high in royal favour, he publicly and privately opposed by his influence and writings the violent measures which were employed by the king's command [Nayrte, P. C.] to bring his Protestant subjects to the Church of Rome. In 1571, on the occasion of the reception of the archbishop of Paris as member of the Academy, he delivered a panegyric on Louis XIV., which was translated into the Latin, English, Spanish, Portuguese, and even Arabic. In 1691, having incurred the displeasure of Madame de Montespan, he was deprived of his office of royal histriographer, but, at the special request of Louis, he continued to write the Life of King Sadiq, which he supplemented in several of his campaigns. Nearly every succeeding year of Pellisson's life was marked by some instance of royal favour. His death took place at Versailles, in February, 1693. The fact of his not receiving the Sacrament in his last moments has been explained by the Roman Catholic writers to be owing to the suddenness of his death, by Protestants to his unwillingness to sanction a conversion, which they allege to be insincere, by a solemn act of hypocrisy. The arguments on both sides will be found impartially stated by Bayle (art. 'Pellisson').

The principal works of this writer, who enjoyed a greater reputation in his life-time than has been accorded to him since, were: 1, 'Historie de France,' which was first published at Paris, in 1653; the best edition is that by l'Abbe d'Olivet, by whom it has been continued, Paris, 1730. The fault of this work is generally considered to have been that a style of the sort was assumed by Bishop Sprat, in his 'Hist. of the Royal Society of London' (part i., sect. 19). 2. 'Historie de Louis XIV.,' which extends from the death of Mazarin, in 1661, to the peace of Nimwegen, in 1678. This history has the faults to be expected in a work of a professed courtier; the best edition is that of Paris, 3 vols. 12mo., 1749. 3. 'Abrege de la Vie d'Anne d'Auvergne,' 1696, in 4to.; a panegyric rather than a history. 4. 'Journal du Temps d'Henri des Jardins.' Two vols., 1696. 5. 'Les Memoires du Pere Demoiselle;' this work has been greatly praised by Voltaire. 6. 'Lettres Historiques et Oeuvres diverses,' 9 vols. 12mo., 1749; the letters, 278 in number, are a journal of the king's journeys and encampments in the above-mentioned campaign. 7. 'Recueil des Pieces Galantes,' 5 vols., 1696, being a correspondence in prose and verse between him and the Comtesse de Suz; his verse parries of the elegance of his style in prose, but it is deficient in imagination. 8. ' Reflexions sur les Differeins de la Religion,' 4 vols. 12mo., an answer to the arguments of Juxo on religious toleration; on this treatise Bayle has made some very interesting remarks in his 'Histoire du Basisme.' 9. 'Traite de l'Eucharistie,' a work he left unfinished. The Prologue in verse of the comedy 'Les Feecheurs de Mollere,' is stated in the 'Dictionnaire des Arts' (vol. i., p. 90) to be by Pellisson, and an edition of the first scene of the play has been published by Deceasta, Paris, 1805, 2 vols. 12mo. (Bayle. 'Diction Histoire.' Biographie Universelle Classique. Dugree. Jaugere. des Moeurs, vol. i., Menagione, vol. ii. p. 16, 89, 207, 301; vol. iii. p. 131.)

PENSTOCK, a kind of small sluice or floodgate, employed to retain or let go at pleasure the water of a mill or other pond. A cut of a simple form of penstock sluice is given under IRRIGATION, P. C., p. 42. See also Sluice, P. C., p. 142.

PENTZ, PENCZ, or PENS, GEORG, a celebrated German painter and engraver, was born in Nuremberg about 1500. He was first the pupil of Albrecht Durer, and he afterwards studied the works of Raphael at Rome, probably after the death of Raphael, but before his school was dispersed. He was a pupil of Pint, as some accounts give, it must have been after the dispersion of the school of Raphael that he was in Rome. He died, according to Doppelmayr, in 1550, at Breslau. His pictures are the most correct in design of the early German masters, perhaps the most correct. His prints are numerous, but his pictures are scarce; there are some at Nuremberg, and a few in the galleries of Berlin, Munich, and Stuttgart; the engraver copy in the edition of 1550, at which he was so busily engaged, by Pints, of which the best are seven of the history of Tobias. He was the pupil of Marcantonio, and assisted in some of his prints after Raphael.

embellish the two palaces of the Tulleries and the Louvre, of which latter more especially the very extensive, numerous, and complicated works fully occupied them for a series of years extended to the restoration of the castle of the Tuileries.

This accounts for the successes we have seen; all their high reputation, been employed on so few buildings; and flattering and favourable as it was, it was not wholly without drawback, because they have aimed at their own architectural creations, and their fame in them merged in the renown of their original authors. One distinct work of theirs is the arch (1806) in the Place de Carrousel, before the east front of the Tuileries, and also on the ground-staircase and other separate portions of the interior of the Louvre.

The chief other monument by them is the Chapelle Expiatoire erected after the Restoration, in memory of Louis XVI. The like is the style of their professional fame, being no more than a handsome and regular piece of street architecture.

For the general celebrity attached to their names, Pérard and his colleague are perhaps, after all, mainly indebted to their publications, and not least of all that entitled "Recueil de Decorations Intérieures, contenant tout ce qui a rapport à l'Aménagement," folio, Paris, 1812, a collection of designs for rooms and various articles of furniture in the ultra-classic style of embellishment that was affected in France at the beginning of the century, but which was so entirely of mere fashion, that Pérard lived to see it pass away. Another publication, known as "Choix des plus belles Maisons de Plaisance de Rome et ses Environs," a series not of strictly architectural studies, but pictorial views of Roman villas and their gardens. To these may be added the subjects of the latter, as recording the ceremonies and pomp at Napoleon's coronation; the other, those which took place on his marriage with Marie Louise. Besides these, there is another work attributed to Pérard, but which did not appear to have got into public circulation, "Parallèle entre plusieurs Résidences de Souverains de France, d'Allemagne, de Suède, du Royaume d'Italie, et d'Italie," Paris, 1833, with thirty-eight plates.

Perard died in Paris, 1858.

PERCOIDE (or Percid), a family of Acanthopergygous osseous fishes, of which the perch is the type. The Percoideæ have bodies covered with rough scales, ciliated at the margin. The shape of the opercle or preopercle is dentilicate or spiny. The vomer, both jaws, and usually the palatine bones, are armed with teeth. Perca, Trachinus, and Mullus are British genera of this family. Beryx is an intertropical percid genus, containing two or three species remarkable for bright-red colours, tinged with golden hues. Holocentrus is a allied genus, including very beautiful fishes, mostly tropical species. Myripristis differs from Holocentrus in the form of its second dorsal spine. Trachichelys is also a genus of this family.

PERIDINUM, a genus of inferior fossils, which occur in flint (Chalk). Pteropoides, a genus of fossil Crinoid echinoderma, found in the Silurian strata. (Austria.)

PERIODUS, a fossil fish from Sheppey. (Agassiz.)

PERKY, JAMES, was born in Aberdeenshire on the 30th of October, 1756. He received the rudiments of his education at the rural parish school of Chapel of Garioch, studied Latin at the grammar-school of Aberdeen, and in the year 1771 was entered a student of Marischal College. He seems to have been destined for the profession of the law, and was for some time employed in the office of one of the attorneys, or, as they are by local usage termed, advocates, of Aberdeen. There are some local traditions of his having been found an inefficient clerk, and the story is still told so much time from the unscientific details of the country practitioner's office, to be devoted to higher-studies, that his master losing all patience dismissed him as incorrigible, and blighted all his prospects of becoming a prosperous country attorney. Perry was master of that ordinary Scottish education which fits its owner for many of the progressive and less-established departments of business or literature. He first proceeded to Edinburgh, where he seems to have acquired a tolerable knowledge of the law. He went afterwards to Manchester, and was rather more fortunate, obtaining employment at clerk to a manufacturer. He had all along occupied his hours of involuntary leisure in cultivate knowledge and experience. He was henceforward to medicine, and went thence in 1771 with introductions to people of some influence in London. Among the friends who had given him general promises of assistance in procuring a situation was Mr. Urquhart the bookseller.

Perry had in the meantime dropped some anonymous contributions into the letter-box of the 'General Advertiser,' which daily appeared in its columns. In one of his unsuccessful visits to Urquhart, that gentleman, who had been highly pleased with his past performance, turned the last subject of his conversation to the 'General Advertiser,' and told Perry if he would like that he would at once procure an engagement. The delighted aspirant claimed the article as his own, and produced from his pocket book the last of which he was about to drop into the letter-box. He was immediately engaged as a stipendiary contributor, both to the 'General Advertiser' and the 'Evening Post.' During the trials of Keppel and Palliser, he furnished the London papers with notes of the reports of the proceedings. Becoming subsequently editor of the 'Gazetteer,' he systematised the method of rapid reporting, by establishing the employment of relays of reporters, which has made so marked a change in the nature of the daily press. He became afterwards joint proprietor and editor of the 'Morning Chronicle,' to which he communicated a decided Whig spirit, which it has ever since retained.

His marked position he was the first selected to be the victim of Sir Vicary Gibbs's attempt to crush the independent press.

On the 24th February, 1810, his case came on for trial before Lord Ellenborough and a special jury, on an ex officio information, and was heard, with great deliberation, but was not decided. One instance of the change was a reprint in the Chronicle of a paper in the 'Examiner' descriptive of the blessings which might be anticipated from a new reign commencing with a change of system. This was resented by the Government; and at this juncture, the Peer himself was a barrier to improvement. Perry defended himself, maintaining his right to inculcate the necessity of improvement, and to look with hopeful anticipations towards any quarter whence it might come. He was tried for his own, and maintained in the paragraph—the necessity of a change—had not been said in one solitary instance, but was the doctrine he had ever promulgated since he had risen to manhood. The jury pronounced a verdict of Not guilty, and the Peer, with informations dropped. Mr. Perry died at Brighton on the 6th December, 1821. He was the author of some pamphlets and poetical pieces, the reputation of which was temporary.

PERPIRATION. (Sav., P. C.)

PESNE or PENE, JEAN, a French painter and engraver, distinguished chiefly for his excellent prints after N. Poussin.

He was born at Bosen in 1626, and died in Paris in 1700. The chief merit of his prints after Poussin is the preservation of the peculiar style of that painter: they are generally of a large size, and are valued by collectors. He engraved also many prints, chiefly after the master, after Annibale, and after Borel.

(Pawlet and Leverque, 'Dictionnaire des Beaux Arts; Huber, 'Manuel des Amateurs, etc."

PETASITES. (Tussilago, P. C.)

PETECHIA (or Petechia, or Petechia), a genus, distinguished as the being of a purplish hue.

PETREHILLY, a village in the county of Lorne.

PETRILLIUS, a genus of plants belonging to the natural order Petiveriaceae.

PETIT SERJEANT. (Serjeant, P. C.)

PETITVERIA (in honour of Mr. James Petiver of London) a genus of plants belonging to the natural order Petiveriaceae. It has 6, 7, or 8 stamens; 4 permanent styles, at length becoming spiry and reflexed; the point is armed with spines at the apex. The species are West Indian herbs, and in pastures are troublesome weeds, giving an unpleasant flavour to the milk of cows which feed upon them.

P. alliacea, Guinean-hen Weed, is a small bush with a disagreeable smell. It bears an erect downy stem, not branched, and of a deep green colour. The leaves are oblong-obovate or oblong-lanceolate, and scarious at the edge, glandular near the petiole, which is both glandular and downy; the stipules are small and spiny. The spikes are long, slender, and drooping at the upper end. The flowers are white, and placed close to the rachis, which is angular; the style is 4-angled, with linear spreading segments, which afterwards become erect, leafy, and cover the fruit. The juice of this plant is exceedingly acrid, and if a small portion of it be chewed it will render the tongue as dry, rough, and black as in cases of malignant fever.

The negro considers it a sudorific, and say that fumigations or vapour-baths of it will restore the motion toparalyzed limbs. The roots are used as an toothache; the negroes also employ it to procure abortion. The plant is rejected by most animals as food. Pittavedas alone seem fond of it; hence its common name Guinean-hen weed.
Marius says *P. tetandra*, another species, is employed in Brazil, under the name of *Roja de pipi*, in warm baths and lotions for defective contractility of the muscles or in paralysis.

(D. Lindley's *Flora Medica*; Burnett's *Outlines of Botany*.)

PETRÓSELIUM (*fetidus,* which means 'rotten parsley,' rock being the habitat of the species), a genus of the Umbelliferae, has an obsolete calyx; roundish entire incurved petals, scarcely emarginate, contracted into an inflexed lobe. The disk is short and somewhat annulate. The fruit ovate and contracted at the side. The species are smooth-branched herbs. The leaves decomposed, with wedge-shaped segments. The involucres many-leaved; the flowers are white or greenish, uniform; those of the disk often sterile. The stamens longer than the corolla segments. *P. sativum*, common Parsley, is described under Parsley, P. C.

P. *sagittatum*, Com. Hornflower, has pinnate lower leaves, usually sessile, leaflets, ovate and serrated, the upper leaves entire or trifid. The umbels are very irregular, the general involucre having from 1 to 5 leaves. The flowers are white, the stems erect, roundish, nearly leafless above from a foot and a half high. It is found on damp soils in a calcareous soil in Great Britain, France, and Switzerland. Goodyer has given an accurate account of this herb, and says that the origin of its name was from the fact of its having cured a swelling in the knee.

The species are easily cultivated and can be raised only from seed.

(Don's *Gardener's Dictionary*; Bahbgton's *Man. of Brit. Bot.*; Lindley's *Flora Medica*; Burnett's *Outlines of Botany*.)

PEUCE, a fossil Coniferous tree, of which the species occur in England. (Edgeworth.)

PEUCE/cANUM (the *Sclerophyll* of Theophrastus and Dioscorides, from *vexxii* a pine, on account of the resinous smell of the plant), a genus of plants belonging to the natural order Umbelliferae and the tribe Peucedanids. It has a calyx of 5 or 6 parts, oblong petals, contracted into an inflexed segment, emarginate or nearly entire. The fruit has a dilated thin flat margin, the carpels with equidistant ridges, 3 dorsal filaments, 2 lateral close to the base of the dilated margin obsolete. The interspace has simple linear vittae. The species are perennial, generally smooth. The leaves are pinnate, more or less compound. The flowers are white, yellow, or yellowish green.

P. officinalis, Sulphur-wort, or Hog's-fennel, is a smooth herb 3 or 4 feet high, with a resinous juice and a strong sulphurous smell. The leaves are four or even five times ternate, with linear lanceolate ovate-acuminate segments. The flowers are white and deciduous; the pedicels are much shorter than the fruit. The fruit of a pale brown colour, the vittae of a deep chocolate; the primary ridges much depressed and paler. The compound fruit has the color of the vittae, with conspicuous vittae evident upon it. It is native in marshy and shady places throughout Europe and in Great Britain. The juice of the root of this plant is resinous and has a peculiar strong aromatic smell. Many sicknesses have been attributed to it, and it is reputed anti-sapromedic and diuretic, but it seems to be rather a dangerous internal remedy.

P. ovoaculins has a taper straited stem. Trifoliate leaves with the petioles broke back, the leaflets remote, ovate, deeply pinnatifid and shining. The fruit is roundish oval. The flowers white with a tinge of blue. The leaves and stem are white from the whitening of the acid cells. They were formerly used as stimulants, and are still esteemed in some countries.

P. montanum is a native of the north and middle of Europe, and is an erecting simple root with many long fibres. The stem is erect from 4 to 5 feet high, hollow, deeply furrowed, smooth branched, and corymbose at the top, and of a bright purple colour at the base. There are about 5 or 6 leaves on a scaly petiole, the leaflets remote, remote, divided; the leaflets are opposite, deeply pinnatifid, dark green and smooth; the petioles straited, smooth, with a reddish membranous margin. The flowers are white and numerous; the fruit is 5-seeded, much larger than the stylos, the calyx, of which is reddish. The root is said to supply the place of ginger in Russia. The whole plant abounds in a white bitter fidded juice which soon hardens into a brown acid resin. It is a famous remedy in Cornish in epilepsy.

P. palustris has 3-pinnae leaves pinnatifid with linear lanceolate acuminate segments, the general involucre of many persistent lanceolate deflexed leaves. The stem is furrowed and from 2 to 3 feet high. The juice is yellow. It is found in Great Britain, but rarely. Any common garden soil will suit the species of Peucedanum, and they are easily raised from seed.

(Don's *Gardener's Dictionary*; Bahbgiton's *Man. of Brit. Bot.*; Lindley's *Flora Medica*; Burnett's *Outlines of Botany*; Lindley's *Vegetable Kingdom*.)

PEVELEY (Sussex, P. C.)

PETZTAL (Herc. of the ancient P. C.S.)

PHACOPUS, a genus of Trilobites, found in the Silurian strata. (Emmerich.)

PHALI/NA (GASTROMETERS, P. C. S.)

PHANEROT/INUS, a genus of fossil Gasteropoda, from the mountains in Scotland of England and Ireland. (Sowerby.)

PHANTASMAGORIA. (Magic Lantern, P. C. S.)

PHARBITIS, a genus of plants belonging to the natural order Convulvulacae. It has 5 sepals, a campanule funnel-shaped corolla, one style, a capitate granular stigma, a 3-celled rarely 4-celled ovary, and 2-seeded fruit. This genus is easily distinguished from others of the same order: they are mostly climbing American herbs, usually beset with retrogenetic spines.

P. Nil has twining annual round hairy branches and stem stalked, 3-lobed, downy leaves, axillary peduncles from 2- to 3-flowered, the flowers large, of a beautiful light bright blue colour. The capsule is much shorter than the calyx, smooth, 3-celled, with two seeds in each cell. The seeds are sold in apothecaries' shops of Calcutta under the name of 'Kal station' and are said to be a purgative and an efficacious speedy cathartic. They are roasted like coffee, powdered, and added to the drug. Some of the doses of fresh leaves are very dangerous to life. It is native of the tropics in every part, and in the South Sea Islands.

There are about fifteen species of this genus, but the one described is the only one of use in medicine. They are however showy plants, and should be reared in a hotbed and then planted out in a warm sheltered situation. A light rich soil or a mixture of loam and decayed leaves suits them best.

(Don's *Gardener's Dictionary*; Lindley's *Flora Medica*; Burnett's *Outlines of Botany*.)

PHASCOCHGERUS. (Sides, P. C.)

PHILLIPS, THOMAS, R.A., one of the most distinguished English portrait painters, was born at Dudley, in Warwickshire, 18th May 1765, and was placed versus his time, with Mr. Edginton at Birmingham to learn to paint on glass; and he came to London in 1790 with a letter of introduction to Mr. West, and exhibited his first picture at the Squadron paintings in St. George's Chapel. In 1792 Phillips exhibited before the Royal Academy a view of Windsor Castle from the north-east; and in the following year he exhibited two historical pictures—the Death of Talbot, and the duel of Sir Walter Raleigh and Sir Walter Devereux, at Egremont, 11th June 1586. He received likewise two pictures of similar classes in 1794—Cupid disarmed by Euphrasyne, and Eliah returning the recovered Child to the Widow. He seems in the year 1796 to have already turned his attention to portrait painting, for from that year he appears chiefly in the Exhibition notices as a portrait painter, though he occasionally painted some historical pieces. It is as a portrait painter that his reputation is founded, and as such he will be known; for nearly half a century he was a favourite exhibitor, and for a great portion of the time the encouragement he met with was not limited to applause, as is often the case, but was substantially patronized, and fully occupied, notwithstanding the rivalry of Hoppner, Owen, Jackson, Lawrence, and others of nearly equal reputation; few however of the nobility sat to him.

In 1804 he received a commission into the 2nd Dragoon Guards, where he remained until his death. In 1808 he was made a member of the Royal Academy, to which he presented a picture of Venus and Adonis as his diploma piece; there is a fine portrait, painted in 1814, by himself at Egremont House. In 1824 he succeeded Fuseli in the professorship of painting, an office which he held until 1832; and he delivered in all ten lectures, which he published together in one volume 8vo. In 1835, dedicated to the Earl of Egremont, under...

Procured, the way of criticism, and the style of his philosophy. In the same way, the title 'Lectures on the History and Principles of Painting;' the fourth, the sixth, and 'the seventh in Composition;' the eighth on Colouring; the ninth on Chiaroscuro; and the tenth on the Application of the Principles of Painting. This book was aott to Dr. and the text is in the form of a philosophical exposition of the subject. It is a work of great merit, and is valuable in its own right. The author, in the third edition, has corrected and improved the text, and has added a number of illustrative examples. The book is a valuable addition to the literature on the subject of painting, and is a valuable contribution to the study of art.
in the usual way and in free contact with the air. It is also found that the phosphorescence does not take place when the wood is allowed to decompose in a damp place. Wood exhibiting this property will retain it for a long period when kept dry. It is therefore possible that. in the case of the wood from which the luminosity is given off during the night at a spot where one of its branches had been torn off. Decaying fungi have been often observed to emit this light. Travellers in tropical climates have observed that when plants containing a milky juice are wounded, the juice frequently becomes luminous, whilst it is descending the sides of the tree. The cause of this phenomenon in decaying plants is probably owing to a slow decomposition of the tissue attended with a formation of oxygen gas, but what determines the development of light under these more than other circumstances is still unknown.

In living plants luminosity has been frequently observed. It is constant amongst some forms of fungi, especially of the genus Rhizomorphae. In the cool-mines in the vicinity of Dresden the species of Rhizomorphae are so numerous as to dazzle the eye by the brilliant light they afford.' [Breslau, P. C. S.] The light from decaying wood, as also from the living Rhizomorphae, continues although they are immersed in irreproducible gases, linseed oil, phosphoric acid gas, oxygen, &c. The phenomenon in both the living and the dead wood of other species of plants is due to the same cause.

Another class of plants in which light has been observed is the Mosses. Several species of the genus Schichtostega, which grow in caverns and other damp places, have been examined for light. Mr. Bancroft and other observers have observed it in this country in the S. penusala; whilst, Funk, Brandenburg, Nees von Essenbeck, Hornschuche, Struve, Unger, Bridel-Bridere and Agardh, have observed it in the same species of the same genus. The light is given off to a small alga, which Bridel-Bridere called Catoptridium smaragdimum, and Agardh called Protococcus smaragdinus, which they supposed was parasitic on the moss. Unger observed that the moss is luminous only in the evening, Bridel-Bridere at night, and in all cases, the moss is emitting no light at all. The moss is luminous on this occasion only, when the moss is immersed in water, and is not luminous when the light of the sun or moon is reflected on the moss. The moss is luminous only when its surface is wet.

Another class of these phenomena is that which is exhibited by the flowers of some plants. The first observation on this subject was recorded by Linnaeus, and made by his daughter Christina Linna. She was walking in the garden one bright sunny evening, when she observed the flowers of Tropaeolum majus to give forth a stream of light. This was attributed by many to an optical illusion, but the fact has since been repeatedly observed on this as well as other plants. We are not perhaps in a position to say this was not an optical illusion; but if it was, one would expect that it should be more constant. It has also been seen by several observers at the same time, in two different gardens, and while others have seen it also. A correspondent of the 'Gardener's Chronicle,' October, 1843, says: 'I have frequently observed the luminous appearance of garden plants, and have looked for a long time to find out the cause. I have seen many on land and more especially on the Papaver papilion, the hairy red poppy, in my garden at Worcestershire. In the evening after a hot dry day, the flashes of light have afforded much amusement to myself and others.'

It is to this phenomenon that Coleoid alludes in the following lines:

"The said on summer's evening hour,
Flattens the golden-coloured flower
A blue electric flame."

Decaying animal bodies frequently emit a luminous appearance, which has generally been attributed to the presence of phosphorus of lime in their skeletons, which become decomposed and yield phosphorus when exposed to the action of organic compounds in a state of decomposition. It is to this cause that the luminosity of putrefying fish is attributed. Light has also been observed on the bodies of those dying of spontaneous combustion. [Combustion, Spontaneous, P. C. S.] But the emission of light is a very constant phenomenon of many of the invertebrate animals under peculiar circumstances. Thus during warm weather, when a vessel passes through the ocean, its sides are suddenly illuminated by a bluish light, and there streaks and stars of a brighter light. This occurs in our own climate, but the phosphorescence is much more brilliant in tropical seas. Poepig, in his 'Reise in Chili, Peru, and the Galapagos,' describes this phenomenon in an equatorial sea. While not all the vessel is illuminated by the last fading rays of the evening sun and the opposite side darkened by the shade of the sails, the sea in this direction already becomes brilliant. One spot after another begins to be illuminated, indistinct stripes of light commence glittering from greater depths, till at last, with the light like a rapid flash of lightning. A great number of these beings are undoubtedly true night animals which conceal themselves during daylight in the deep dark depths of the ocean.

These lights in the sea are principally produced by various species of the family Acalephae, or jelly-fishes. The light emitted by these animals seems to be due to the secretions on the surface of their bodies, for when this secretion is removed it retains for some hours its luminous character, and will even impart it to milk or water. But this property is not confined to the Acalephae; many species of Polypterus, some of the Echinodermata, and the lower forms of Mullusca, also exhibit this appearance. Some few of the Crustacea and even fishes have been observed to possess the same property.

Amongst insects this phenomenon is not uncommon. Those which possess the greatest luminous power belong to the Coleoptera and some cases of the beetle tribe.

(Meyen, Eptauen-Physiologie, Band ii.; Carpenter, Animal Physiology; Lankester, Gardener's Chronicle, 1843.)

"PHOTOGRAPHY."

In the brief notice of this art given under Photogenic Drawings, P. C., p. 113, very slight reference is made to any other processes than that of Daguerre. The following notice of the light emitted by light in a camera obscura, is, by chemical agency, permanently impressed upon prepared metallic plate; although it is indicated that similar effects had been, though less perfectly, introduced a few years previously. 'The experiments of Mr. Sowerby, containing details of native sulphate of barytes, found near Bologna, at Monte Patero. He observed that whenever this mineral had been sufficiently heated, it acquired the property of shining in the dark after having been exposed to the sun's rays for a short time, at which it would even continue thus to emit light for some hours. The best mode of preparing this phosphorous became a subject of no small pecuniary importance, and a family of the name of Zagoni appear to have been the most successful preparers of it; their process however is not exactly known; but if sulphate of barytes, obtained from any source, be powdered, made into cakes with gum tragacanth, and calcined carefully, they will be found to answer the purpose.

PHOTOGRAPHY.

In the brief notice of any other art given under Photogenic Drawings, P. C., p. 113, very slight reference is made to any other processes than that of Daguerre. The following notice of the light emitted by light in a camera obscura, is, by chemical agency, permanently impressed upon prepared metallic plate; although it is indicated that similar effects had been, though less perfectly, introduced a few years previously. 'The experiments of Mr. Sowerby, containing details of native sulphate of barytes, found near Bologna, at Monte Patero. He observed that whenever this mineral had been sufficiently heated, it acquired the property of shining in the dark after having been exposed to the sun's rays for a short time, at which it would even continue thus to emit light for some hours.

The best mode of preparing this phosphorous became a subject of no small pecuniary importance, and a family of the name of Zagoni appear to have been the most successful preparers of it; their process however is not exactly known; but if sulphate of barytes, obtained from any source, be powdered, made into cakes with gum tragacanth, and calcined carefully, they will be found to answer the purpose.
practical perfection. The peculiarities of Daguerrotypes, pictures being already described under Parochomic Drawings, P. C., it is only necessary here to refer to some of the more important recent improvements, in consequence of which the practice of this art is steadily gaining ground, it being already extensively used in other parts of the world, such as the United States, Canada, and other countries, as well as in the manufacture of buildings, &c. A pretty full account, illustrated with engravings of the apparatus employed, of the Daguerrotype process, both as originally practised in this country under the name of the Daguerrotype process, in its branch of papier-maché, &c. by Mr. Richard Beard and M. A. J. F. Claudet (both of whom had purchased licences of M. Daguerre), is given in the Supplement to Dr. Ure's Dictionary of Arts, &c. art. Daguerrotype. Of late improvements are reported. 'Bulletins of practical applications' of the Society of Arts (pp. 89-110), is a paper presented to the Society, in December, 1843, by M. Claudet, on The Progress and Present State of the Daguerrotype Art, in which much valuable information is conveyed. In addition to such improvements as could only be satisfactorily explained in connection with a minute account of the process, these sources of information show that much has been done in rendering Daguerrotypes portraits more correct and more pleasing by the improved management of light, and by placing behind the sitters painted screens, to relieve the head, and to form artificial backgrounds. One of the greatest difficulties in the original method was that there seems no way in which the reflecting or refracting produced in the camera-obscura was totally invisible until brought out by a subsequent exposure to the vapour of mercury, it was impossible to tell precisely at what moment the action of the light on the plate was to cease. In the hand, an image imperfectly developed, and, on the other, the misty, indefinite appearance occasioned by the unavoidable motion of the object to be copied (whenever it is an animate object), and the discoloured or burnt appearance of an image which has been exposed too long to the chemical action of light. This inconvenience is remedied by M. Claudet's method of applying the mercurial vapour in the camera-obscura simultaneously with the object. By placing in the camera-obscura an image, and providing means to enable the operator to watch the progressive development of the image. One important class of improvements has reference to the means of fixing and securing from injury by the subsequent action of light or other means, the Daguerrotype image. M. Claudet, in the paper above referred to, after alluding to some inventions for this purpose, observes, that 'it was left to Mr. Fox Talbot to discover what has proved one of the greatest improvements in the Daguerrotype process, and which consists in fixing the delicate image by means of a transparent coating of gold, applied by boiling upon the plate a solution of chloride of gold, which not only renders the image more durable, but has the advantagous influence of bleaching the tint, so that a picture fixed by Mr. Fox Talbot's process is rendered more forcible, and the mirror-like effect is almost destroyed.' 'And so,' adds F. C. H. A., 'pp. 92, 99, is an account of experiments, by M. Ules, of Havana, which were in the same direction as that of M. Claudet, and which show that the durability of Daguerrotype impressions, from which it would appear that they may be rendered insensible to the action of light, and of some more trying chemical agencies; and that, whenever it is desirable, the image, or rather, the former, or representation of the latter, may be reproduced by the action of heat. On p. 292 of the same volume is an announcement of a method of Daguerrotype fixing, by Professor Böttiger, of Frankfort-on-the-Main, by which, however, it is observed that 'as yet he has only succeeded in bringing out three colours, of which the flesh-colour is the most perfect.' In the absence, however, of any further account of this invention, we are led, from the results obtained by the practical experimenters, to suspect that in this, as in the other cases above to be mentioned, the colouring was not simply the result of the action of variously coloured rays, but of a uniformly coloured Daguerrotype, some of which may be tolerably near approach to the effect which might be expected if colours could be fixed in the camera-obscura, the lining produced by the application of fixed image being preserved in the Daguerrotype impression, which is previously coated with an alcoholic solution of copal, and nearly dried; so that the colouring, which is so delicately performed as not to impair the distinctness of the image, and yet, as may be inferred from the photographical impression, is already present on the surface of the plate. Since this mode of colouring photographic drawings has been in use, a new and ingenious process has been invented by C. G. Page, professor of chemistry in Columbia College, U.S., which consists in heating the Daguerrotype plate, and washing the surface with a solution of wine, and then of the oxides of copper upon the surface of the Daguerrotype plates, in lieu of the deposit of gold invented by Ficeau. An account of this process, reprinted from 'Stillman's Journal,' appeared in the Athenæum for 1845, p. 277. Mr. Ficeau, the inventor of the mode of fixing Daguerrotypes by a golden deposit, has also devised a process, of which an account was presented by Mr. Godfrey to the British Association in 1846. Mr. Godfrey's Daguerrotype is a product of christian cement with the aid of an acid menstruum; by which means the Daguerrotype is converted into a perfect, though very faintly-engraved, plate, capable of yielding impressions. Though too delicate for use under ordinary circumstances it may be finished by an engraver, and it is anticipated that the process may be advantageously applied to minute anatomical illustrations, and similar purposes in which the utmost fidelity and delicacy are requisite. M. Claudet, in the passage already quoted, mentions the names of M. Donné, of Paris, Dr. Berres, of Vienna, and Professor Grove, in England, as having, concurrently with Mr. Ficeau, attempted to accomplish this object. Before turning to other branches of the art of photography we may quote from the conclusion of M. Claudet's paper the remark that, notwithstanding the very recent origin of the Daguerrotype, it already ranks as one of the most prominent inventions of the present day, leaving scarcely anything to look for in the way of improvement. 'It is true,' he adds, 'that it remains to find the means of reproducing the natural colours of objects; but, although the colour is not yet perfect it is distinctly instructive; and, as the progress of science, and with the properties of the known elements, that of the Daguerrotype is yet in the first stage of its existence, we may anticipate that it will attain high perfection and perfection will be a matter of time.' The process invented by Mr. H. Fox Talbot, and known most commonly by the name of Calotype, but recently called, in commemoration of its inventor, Talbotype, is a photographic process which does not present one single fault which, though not brought to so great perfection as regards the representation of minute details, claims some important advantages in point of cheapness and convenience. Mr. Talbot's method has been most extensively applied to amateur purposes, and to try to use the camera-lucida for the purpose of sketching, in October, 1833; but although his photographic researches date from that time, his invention of the Calotype process was not completed until September, 1840, and in this time some minor improvements have been made. Both the original invention and its subsequent modifications are secured by patent. In a description of the process communicated shortly after its invention to the Royal Society, and published in the Athenæum for 1841, pp. 540, 541, Mr. Talbot gives directions, from which the following are abridged, for the preparation of the photographic paper which, in this branch of photography, is used instead of the silvered plate, of Daguerre.
In light and shade. 'It is evident, then,' he proceeds, 'that all bodies are capable of photographic disturbance, and might be used for the production of pictures, did we know of easy methods to suit them well for this purpose; and we are not without hope that these means may be discovered. It must be remembered that in all the best photographic processes, the images are invisible at first. In the Calotype process, as they are also in the Daguerréotype, the picture is brought out by chemical vapour. In the Chromotype, nitrate of silver is the active material for the same purpose; and it may be used to bring out pictures under similar circumstances to the silver paper. In the Chrysotype, a beautiful process discovered by Sir John Herschel, a dormant picture is brought into view as a powerful negative image, by washing the paper with chloride of gold.

In the Cyanotype, the same phenomenon has been under the influence of the ferro-prussiate of potash. The Ambrotype, and some other processes, the result of the researches of the same investigator, Sir J. Herschel, are of a remarkable character: the pictures remaining dormant so long as the paper is kept dry, whilst the simple process of breathing over it discloses the hidden picture with wonderful intensity. Lastly, the Energieotype, or, as the discoverer now names the process, the Ferrotype, enables us to keep the pictures invisible on the paper, and to reveal their image by a blow of force in an instant, by washing with a solution of an iron salt.

These are but a few of the curious phenomena which have resulted from the discoveries of Niepce, Daguerre, and Talbot.

Arago even declares that the discovery of Daguerre's process, 'In this instance, it is upon the unforeseen that we are especially to reckon.'

That we are as yet only beginning to understand this curious branch of physical science, is manifest from the uncertainty which yet prevails as to the precise nature of the agency by which photographic impressions are produced. Several phenomena have been observed which lead to the supposition that the remarkable chemical changes which such impressions are produced are not due to the simple action of light itself, but of 'some power associated with it, which, according to the writer from whom we have just quoted, 'may possibly be the result of some action of the air; and it does not appear,' he adds, 'from experiments described by Mr. Hunt, that we can separate, to a certain extent, these influences one from the other by coloured media."

There are, therefore, he subseqently observes, 'to inquire. Is this a new element, distinct from light, heat, and electricity, or is it a modification of one of these?' Further researches only can settle this point. Sir John Herschel proposed the epithet of Actino-chemistry for this new branch of physical-chemical science, and it has been suggested that Actinum would be an appropriate term to distinguish this chemical power from the light and heat with which it is associated. As a subject for the future, the full subject to the circumstance mentioned by M. Claudet in his paper already referred to, that the operation of the Daguerréotype has been found to be much slower, with the same brilliancy of light, in the moonlight than in daylight; as to the evidently different effects produced in the Talbotype process by different coloured rays, a circumstance which renders the foliage of some landscapes thus produced very defective. In a review of 'The Pencil of Nature,' in the 'Athenaeum' for 1845, p. 693, it is observed that perhaps this defect might be remedied by some alteration in the paper, and we are informed that paper prepared with bromide of silver, if exposed to the purer sections of the spectrum, will be found to be equally sensitive to all the rays.

In this paper is an important correction of an erroneous notion which appears to have been commonly received, that the light of the moon would not act photographically. It being supposed that the chemical principle, or actinum, of the rays of solar light was absorbed by the moon's surface. In answer to this we are informed that photographic impressions have been obtained by moon-light both upon Daguerreotype plates and upon paper, whereby showing that the moon's beams are of the same character as, though of less intensity than, the rays received directly from the sun. Both kinds of photography have also been produced by light emitted from lime ignited by the oxygen-flame.

Of an art so new it would be premature to attempt to enumerate the advantages. Among the more obvious may be mentioned the power of utilizing the agency of any unperceived, or even in such a most complicated scenery, to be used in aid of an artist's memory for the production of landscapes, architectural re
PHYLLODOCO, a genus of plants belonging to the natural order Ericaceae. It has a 5-parted calyx, an ovate corolla with a contracted 5-toothed mouth, 10 stamens enclosed, slender glabrous filaments longer than the anthers, short truncate cells opening by pores at the apex. The seeds are compressed and shining. The species are small evergreen shrubs, natives of the north of Europe, Asia, and North America.

P. coriacea has linear leaves with denticulated margins, glabrous hairy peduncles; calyce lanceolate-acute segments; petals three times as long as the glabrous filaments. The stem is from 4 to 6 inches high, determinately branched, inked below, densely hairy above. The flower is large, pale yellowish red; the peduncles terminal, aggregate, and simple. This species is found either in the north of England or in Scotland. There are three other species of Phyllodoce, which are natives of North America. They thrive only in a peat soil, and are propagated by layers. They are a genus of elegant shrubs, but rarely shrubs.

P. somnifera has several shrubby branched stems, round and downy. The leaves are in lateral pairs, short stalked, ovate, downy, and from 2 to 4 inches long. The flowers are axillary, subsessile, small, crowded, and of a greenish yellow or white. The berry is red and smooth, and about the size of a pea. This plant is the strobex of the ancient myths, and is still used in the Middle East. It is reputed to be of great medical and alchemical value. The leaves steeped in oil are applied in India applied to inflammatory tumours, and they are used in a similar way in Egypt. Kubh recognised this plant in Egyptian mummies.

P. Alkekengi, the Winter Cherry, is an herbaceous downy plant, with a perennial creeping root; ovate deltoid leaves; spotted flowers, ovate coloured calyx, and subulate segments. It is a native of Europe on exposed hills, and of Japan. The corolla is a dirty white; the calyx reddish yellow, enclosing a red berry. The flower of this plant was well known to the ancients, and is described by Dioscorides. In this country, however, the fruit is seldom eaten, and the plant is cultivated chiefly on account of its appearance. In Arabia and Armenia, Spain and Germany, however, the berries frequently supplicate the double nature of the plant. The leaves have a sweet and not unpleasant flavour, but the persistent calyx with which they are invested is very bitter. Ray speaks of these berries as a preventive of gout, and others have extolled them as diuretics, and recommended them in the treatment of dropsy.

P. pubescens, Downy Winter Cherry, is a native of North America and the East Indies. It is a widespread plant, densely clothed with hairs, and bearing yellow flowers with roundish brownish violet spots at the throat. The berries are yellowish when ripe; they are called gooseberries, and are used as a substitute for them in many parts, and when preserved with sugar, they are much relished. It is the Concora of Brazil. All the species of Physalis thrive best in a light rich soil, and are easily propagated by seed, and cuttings will take root under a hand-glass.
which place he accompanied his father in 1710, he worked exclusively for the booksellers, and became mannered, metallic, and merely ornamental. A great many of his prints are from his own designs, in which he imitated the style of contemporary Dutch and Flemish art. He taking the styles of other earlier engravers, and he published many prints of this class which are said to have deceived collectors; Pierrat used to call them Impostures innocentes, and they were published under this title, to the number of 78, with a list of his works, at Amsterdam, in 1718, after his death. His prints altogether amount to about 1500; and one of the best of them is a Slaughter of the Innocents, after a design by Michelangelo, which shows various impressions of it. During opening the Tomb of Ntirisa, after Le Sueur, is also one of his best prints; it is much in the style of Girard Andran. He died at Amsterdam in 1738. (Wattelet et Levenque, Dictionnaire des Arts, &c.; Huber, Manuel des Amateurs, &c.)

PICO is one of the Azores, or Western Islands, so called from the remarkable volcano which it contains, and which is called the Peak (Pico). This island lies between 28° 25' and 29° 42' W. long., and between 38° 15' and 38° 33' N. lat. It extends from west-north-west to east-south-east about forty-five miles, and is about eight wide towards its western extremity where it is wide. It grows narrower as it proceeds farther east, until it terminates in a forked rock hardly a mile in width. The average width is about five miles. This gives an area of 220 square miles; which is the size of the Isle of Man.

The coast-line is formed by rugged rocks, which form no port nor allow an anchorage; at Lagens, on the south coast, is a small cove, in which small craft find shelter. The western districts face the great rocky surface of the country rises from the shores towards the peak, which occupies the centre of this part of the island, and is more than 8000 feet above the sea. The soil is composed of lava, which in many places is covered with a thick layer of earth, formed by the decomposition of volcanic matter. The country round the volcano and even the lower parts of its sides are richly cultivated, principally with vineyards; there are no other cultivated crops except corn and potatoes. The soil is black and fertile. From the cultivated grounds to within a third of the distance from the summit, it is thickly covered with splendid cedars, the myrica faya, the white yew, immense junipers, myrtles, and trees-ferns, beyond which point vegetation begins to decline, and on approaching the top of the peak nothing is seen but moss and lichens. From the eastern base of the volcano a high ground runs eastward to Cape Calhugrass, the eastern extremity of the island. It occupies the middle of the island, and descends with a very broken surface towards the northern and southern shores. Though this part of the island also consists of lava-rocks, it contains a much larger portion of earth than the rest, and is not separated from the country round the volcano. The southern declivities are much better cultivated than those which slope towards the northern shores, which are less covered with soil.

The vineyards are well cultivated, and lately there were annually exported nearly 25,000 casks. It is considered better than any kind grown in the Azores, and goes by the name of Faylor wine, because it is brought to foreign countries from Horta, the capital of the island. Great quantities of fruit are also sent to Faylor. Grain and pulse are grown sufficient for the consumption of the population; the onions of Faylor are much valued, and large quantities of them are disposed of to the Americans and other traders who frequent Faylor. Among the forest-trees, the cedar and white yew are greatly prized for furniture, nearly as much as mahogany, and are exported to the West Indies and to Europe.

The climate is mild, neither the cold of the winter nor the heat of the summer being intense, but it is very irregular. No decidedly settled weather can be calculated on except between the months of March and the beginning of November, the rest of the year being subject to sudden changes. Showers of rain are frequent throughout the year, and the winds are subject to great changes in the winter so violent as to cause constant changes in the face of the country, washing away enormous masses of pumice from the shores and beds of the rivers, accompanied by showerings down of volcanic materials, and leaving the surface of the rocks and heights in many places destitute of soil. This island, like the other Azores, is subject to incessant gales, which render the approach to it dangerous to vessels. Earthquakes are frequent, and four eruptions of the volcano are on record. Three of them occurred in the sixteenth century, and the last in 1718, which burst from the western side of the peak and overflowed the whole river course in the facility in which it usually proceeds.

The population, which is stated at 30,000, consists of the descendants of the Portuguese who settled in the Azores in the fifteenth century. They are an industrious race, and are settled on the shores of the island, where they live in many white cottages, with bright, cane-reed thatched, conical roofs. The capital is Lagens, a small place built round a small cove. In the strait which divides Faylor from Faylor, but at a short distance from the island approaches the congregations of rocks. This rock, called the Isles of Magdalen, and between them Pico is an anchorage in six to eight fathoms. Opposites to them is the town of Magdelena CristoVella, whence the produce of Pico (wine, brandy, fruits) is shipped to Faylor, and where the rich inhabitants of Horta have villas.

It is not ascertained when Pico was first settled, but probably many years after 1466, when Faylor was occupied by a colony of Flemings, who were soon afterwards followed by the Portuguese. It was not till the best portion of this island had been settled, that the inhabitants passed over to Pico, which is so difficult of access. It has always remained in the hands of the Portuguese.

(Anhée's History of the Azores; Boldt's Description of the Azores; Von Buch's Physikalische Beschreibung der Con- rischen Inseln.)

PICI is a genus of plants belonging to the natural order Compositae, and the suborder Cichoraceae. It has an invio- lence of one row of equal scales, with unequal linear, often spreading, scales at the base; the receptacle is dotted; the fruit terete, ribbed, or furrowed, is thin, often rounded, with a pappus of two rows, feathery, external row sub- pilose. P. hieracoides, the only British species, has rough leaves, with forked and hooked bristles, lanceolate leaves, and dentate or serrate, the larvae leaving a head solitary, terminating the stem and branches, the outer involucral scales lax, oblong, bristly on the keel, glabrous on the margin. The fruit constructed just below the pappe. The flower is yellow, the caryopsis is black in colour. This species is found on dry banks in Great Britain.

(Babington's Manual of British Botany.)

PIERMARINI, GIUSEPPE, an architect who occupies a foremost place among those of Italy during the latter half of the eighteenth and at the beginning of the present century, was born at Foligno, July 18th, 1734. His father (Pietro) was a merchant, and intended that Giuseppe should apply himself also to business, where he had only to pursue the course opened and prepared for him, in order to prosper. Nor does he seem to have at all rebelled against paternal wishes, except that his bent of mind led him to give his at- tention more to studies than to trade. Having constructed for himself a geographical globe, 20 Roman palms (about 14½ English feet) in diameter, it attracted many visitors, and among others the celebratedmathemate- cian D'Alembert, who recommended his father to send him to Rome to pursue his studies systematically under proper instructors.

He was nearly twenty years of age when he went to Rome, and, eager to make up for lost time, applied himself with arduous to mathematics and architecture, which last he studied first under Poggi, and next under Vanvitelli (Vanvitelli, P. C.), who conceived a particular regard for him. The master was sincerely desirous of bringing his pupil forward, and afforded him every opportunity of gaining practical instruction, the means for which were abundantly supplied by Vanvitelli's numerous engagements. On Vanvitelli's going to Naples to erect the palace of Caserta, he took Piammarino with him as his principal assistant in that extensive work. Again, when Vanvitelli was afterwards invited to Milan, by the Austrian government, for the purpose of altering and embellishing the palace there of bricking, the Cesarina Imperiale, for the Archduke Ferdinand, Piammarino accompanied him; and for Piammarini this proved a singularly im- portant event. Meeting with obstacles and having other engagements, he was prevented from acquainting himself with making some general designs and explaining his ideas, and recommended his pupil as fully competent to supply his place. The work was accordingly transferred to Piammarini (1769), who carried out his schemes. Piammarini established at Milan, the city destined to become the chief theatre of his professional labours, with the title of archi-
pect to the archduke, and inspector-general of buildings.

After the Academy of Fine Arts at the Brera being established, he was appointed to the professorship of architecture. For thirty years Piermarini was constantly employed at Milan, which is indebted to him not only for most of the principal buildings by him are the palace of the pope, Mortegita, Lancem, Sannazzari, Litta, Cusani, and the magnificent and extensive façade of the Palazzo Belgioioso; also one of the fronts of the architect's palace. Among his public buildings are the Monte di Pilgr, the Monte Napoleon, the Longhi Pil, the Teatro della Canobbiana, and the Fora Orientale, his designs for which were adopted in preference to Cagnola's. [CAGNOLA, F. C. S.] He likewise conducted many general public improvements, such as several new streets, the Piazza del Tagliamento, and almost the whole of the new quarter called the Contrada di S. Redegonda; which to may be added the Public Gardens and their buildings. Nor were his labours confined to these, as many of the ancient imperial villa at Monza; also of the Villa d'Adda in Cassano, and of the Villa Cusani at Desio, at which place he improved and completed the church.

Since his youth political changes and the state of public affairs induced him to withdraw altogether from Milan, and retire to his native town Foligno, where he occupied himself with his favourite studies, and formed a valuable collection of books, among which, amongst others, are works upon art. There he died, February 18th, 1608. The Academy of the Brera, at Milan, honoured his memory with a monument in the portico of its building.

(P. V. Veronese, in Velasso, Biografie, &c.)

PIG. [HOG, F. C.; SUDDE, F. C.]

PIG-NUT. [BUNN, F. C. S.]

PIGALLE, JEAN BAPTISTE, a celebrated French sculptor, was the son of a carpenter, and was born at Paris in 1714. He was the pupil of Robert Lorrain and the elder Lemoine, and studied three years in Rome. On his return to Paris he attracted great notice and obtained a permanent reputation for a statue of Mercury. The king (Louis XV.) purchased the statue, and the Royal Academy of Painting and Sculpture elected Pigalle a member. Louis XV. ordered the sculptor to make a Venus as a companion to this Mercury, which, however, was considered unequal to it, and the king proposed to send it to Madame du Barry, which he was unwilling to consent to. On the other hand, the material for the Venus was of the most extraordinary quality, and the king proposed to make a copy of it. Pigalle was induced to make the Venus, and the statue was exhibited at the salon of 1745.

PIGALLE'S VENUS, which is now in the Louvre, is one of the most celebrated statues of modern times. It is a group of the statue of Venus, and the personification of the female figure, and is placed in the centre of the room. The Venus is represented as reclining, and is supported by a column, on which is a figure of Mercury. The statue is of marble, and is of the most exquisite workmanship. It is a fine example of the power of the French school of sculpture, and is a proof of the taste of the king, who was averse to the Egyptian and Greek style, and preferred the Roman style.

PISTANO is the surname of several distinguished artists of Pisa in the thirteenth and fourteenth centuries. Pisa, Niccola, Giovanni, and Andrea Pistano. Of two of these artists, Niccola and Giovanni, some account is given in the Penny Cyclopedia. Andrea Pistano, the third of the name, was born at Pisa in 1329. Vasari commences his "Lives of Artists" with Cimabue, and there were several Tuscan artists anterior to Cimabue, especially at Sienna and Pisa. [Tuscan School of Painting, P. C.]

GIUNTA PISANO was one of the principal of these three artists, and is the earliest known Tuscan painter; Niccola was a sculptor, and Giunta appears to have preceded him for a time, though Vasari has erroneously put him in another group, and as they were contemporaries, the name of Niccola accordingly takes the lead in the list of celebrated Tuscan artists. Giunta may have been born about 1180 or 1190. He is said to have learned painting about 1210, from some Greek artists, who were then engaged probably at Pisa, a tradition which is disputed by some Italian historians of art, who suppose that Pisa had at that period its native artists. The arts were very active at Pisa, owing to the construction of the cathedral there, which was commenced in 1063. The notice of Giunta in question occurs in an old history of the Basilica of Assisi, by Peter Angell, who says, "Janetta Pisanus riditet a Graecis historiae primum ex Italii artem appetit comprehendit circa annum 1210."

Giunta appears to have attained considerable reputation, for Pisa. Elia of Cortona, general of the Minorities, invited him and his son to Assisi, to execute some works in the upper church of San Francesco. There are still some remains of the paintings of Giunta in this church, around the window behind the altar. He painted also a Crucifixion in 1214, and the predella of the so-called "Assisi Elia." These painters of this time were acquainted with some excellent water-colour medium, for another Crucifixion at Assisi, with other figures, painted upon a wooden cross in the church of San Francesco dell'Albergata, by Giunta, remarkably solid in impacto and unaffected by water; it was painted probably about 1236, and has the following inscription upon it, according to the restoration suggested by Lanzi: "Juncta Pisanus junctaque sorsam Giuntai di Assisi commentavit domini," the name, from the occurrence of this name in an old MS. mentioned by Morrona in his "Pisa Illustrata." Other existing works ascribed to Giunta are—a Crucifixion in San Miniato al Monte at Pisa, a picture (a panel) of Saints in the chapel of the Campo Santo, and a Martyrdom of St. Peter in the church of San Francesco at Assisi (it is engraved by Lanino in the "Etruria Pittor" of Lastrici). The Campo Santo was built or commenced by Giovanni Pisano in 1278. (Archaeologia, vol. xxxi., pt. 1.) Giunta was contemporary with Guido di Sienna and Bonaventura Berlinghieri of Lucca; and all belong to the Byzantine school in style—brownish colours, positive compositions, exaggerated features, and a coarse line with hatchings for the shadows, and elongated extremities, even with occasional short thick figures; but their forms are generally attenuated and emaciated. This degenerate form however had an historical significance;—as sorrow, resignation, or bodily suffering are almost exclusively the sentiments expressed in early paintings; as we also generally find to be the case in MSS. These peculiarities of style were not much improved until the time of Giotto, and not wholly corrected until Masaccio, two centuries later than Giunta. They were, said Lanzi, faults of the times rather than of the men. Mr. W. Y. Ottley possessed an old Italian distraster picture of the Crucifixion, which he supposed was a work by Giunta. Vasiari has omitted the Life of this painter. There is no notice of him later than 1326, but he may have lived some time beyond that date. 1821.

ANDREA PISANO was another early artist of Pisa, but nearly a century later than Giunta and Niccola Pisano. He was born in 1260, was distinguished as architect and sculptor, and celebrated as an earlier founder, in 1316, of the first of his age. He is said by Vasiari to have imitated the design of Giotto in the Campo Santo. He was invited early to Florence, where he executed several celebrated works. The most important seems to have been for the Baptistry, for the façade of Santa Maria del Fiore; they are now, with other works by Andrea, in the Strozzi garden on the Volonda; the pope is engraved in Cicerone, Scipione, and Sella. Vasari describes the colossal Madonna and Child, and the two accompanying angels, in marble, in the chapel della Misericordia of the Piazza San Giovanni at Florence, but this was the work of Alberto di Arnoldo in 1304; the error was detected by Vicenzo Follini: the documents are given by Cicognara and Rumohr. The half-figure of the Madonna above a side door of the Misericordia, on the wall of the Chalidrop, is the work of Andrea Picciotto. Andrea was also appointed, contrary to his usual custom, he imitated the antique. Andrea's great work in sculpture, however, was the bronze gate for the Baptistery of St. John, which he undertook to make from a design by Giotto. It was completed in 1325, during the pontificate of John XXII. He had a few years previously sent Pope Clement V. (1305-1314), through Giotto, a bronze crucifix as a present, and the excellence of this work led to the important commission to model and cast two of the bronze gates of the Baptistery, which, after the lapse of twenty-two years, says Vasiari (Baldinucci says eight years). In 1339, with the assistance of his son Nino, he successfully accomplished; not that he was all this time exclusively occupied on this work, for he executed many others in the meanwhile. The sculptures are from the life of John the Baptist, and were gilded, and the gates were fixed up in the central entrance to the Baptistery; but upon the completion of the much more excellent gates of Ghiberti, they were removed to one of the side entrances, and those of Ghiberti were put in their place. The year 1339 in Vasiari appears to be a misprint; for, according to most good authors, the gates were the following: Andrea Ugolini Nini de Pisa me fecit anno domin. MCCXXX. (Cicognara, Storia della Scultura, iii. 396; and Lasinio, Le tre Porte del Battistero di Firenze, Florence, 1823, in the Pisa Library, there are some works of the period). But this date, according to Giovanni Villani, one of the superintendents of the work, is the year in which they were commenced; if therefore they occupied twenty-two years from this time, the year 1325 could not be correct. The work was done by Venetian artists, the model only being finished in that year; they may therefore have occupied twenty-two years from the commencement of the model to the completion of the cast of the gates, which was done in two years, after Giotto's return from Avignon, as the date of the commencement of the work, which is quite probable. As an architect, Andrea designed the Castello di Scarperia in Mugello at the foot of the Alps; and Vasiari says, according to report, the Arsenal of Venice, where he spent a year; he raised part of the walls of Florence eight ells in 1316; he designed the church of San Giovanni at Pistoia, commenced in 1337, and he executed many works for Guido, duke of Athens and tyrant of Florence, until the duke was expelled from Florence in 1343. Andrea was murdered on a visit to Florence, and had other honours conferred upon him. He died in 1345, and was buried in Santa Maria del Fiore, where his son Nino raised a monument and placed the following inscription to his memory:

In gentem Andreae natus hic Putane in urbe,
Marmore quo pictae emplures doceat valvis.
Ex similibus Deum media impone templis
Ex arbo, ex arbo undantem et palatis elephante.

Nino completed the unfinished works of his father, and executed many original works of merit. Tommaso Pisano, another pupil of Andrea, is supposed also to have been his son. (Vasiari, Vite de' Pittori, &c., and the notes to the German translation by Schorn; Lanzi, Storia Pittorica, &c.; Cicognara, Storia della Scultura; Köbler, Kunsthallt, 1827; Bembo, in the "Bollettino delle Scienze Archeologiche di Napoli, Storia de' Pittori, &c.,"

PISCARY. [FISHERS, P. C.]
PISCARY (from pieces, a fish, and eel, to kill or destroy), a fish, a large common species of the genus minocyclus. It has a campanulate 5-leafed calyx, an obtuse keel, and a papilionaceous corolla. The stamens are monadelphous, with the tenth one free at the base. The style is filiform and smooth, the ovary 3-celled, and St. Paul, from designs by Giotto, for the façade of Santa Maria del Fiore; there are now, with other works by Andrea, in the Strozzi garden on the Volonda; the pope is engraved in Cicerone, Scipione, and Sella. Vasari describes the colossal Madonna and Child, and the two accompanying angels, in marble, in the chapel della Misericordia of the Piazza San Giovanni at Florence, but this was the work of

P. erythrina (Dogwood) is a tree about twenty feet high. The leaves are in pairs, from 3 to 4 together; they are oblong or obovate, rounded at the base, downy on both sides
machinery was made, according to Nicholson's Architectural Dictionary, by General Bentham, who patented a plan in 1791 for a contrivance by which large planes, wide enough to take the whole width of a plank at one stroke, and supplied with apparatus for directing their course, regulating the depth of the cut, and generally effecting the necessary degree of skill and judgment on the part of the operator, might be worked either by mechanical power or by manual labour. The machine was used for a time, worked by hand, but did not succeed well. A patent was obtained in 1803, by a person named Berens, for a similar apparatus for planing, or, to use a technical term, 'sticking, mouldings, reliefs, grooves, &c. The improved principle, now generally adopted, of making the wood to be planed to adhere closely to the teeth of a severe toothache, he took a powerful dose of the tincture, which was succeeded by a profound sleep and entire relief from pain on awakening. As a topical application to various teeth it is said to possess tanning qualities. It is one of the best timber-trees in Jamaica; the wood is coarse, heavy, resinous, and almost imperishable, lasting equally well in or out of water; hence it is said to be used as a table-leaf, as it would be useless to throw it into pure sea-water, and neither its flavour nor wholesomeness is in any degree impaired. The same gentleman made a series of experiments on himself as to the effect of a mixture of opium and ferrum phosphoricum on the tooth and gum, and hence the genus of P. Carthaginis is a native of Jamaica, Guadaloupe, and Carthagea, on the mountains. It closely resembles the former species, and is scarcely distinguishable from it. These trees are also much more commonly rootage of them may be rooted in sand under a hand-plant in heat.

**PLANE: PLAINING THE MACHINERY.** Of the planes commonly used by carpenters and cabinet-makers for levelling and smoothing the surface of wood, an account is given under *JOSEXT, P. C. S., p. 123, where the use of what is termed a double-iron is briefly alluded to. This improvement, which has been in common use for many years, is not found sufficient, in all cases, to meet the difficulties which arise in planing hard and coarse woods. To remedy this defect Mr. C. W. W. Thomas has invented and obtained a patent for the same in 1825, where he terms a double-bevelled plane, in which a single iron is used, but it is made thicker than those of ordinary planes, and its edge is produced by two bevels instead of one, and what is more it is made with an inner edge of which is 'much stronger, will retain its keenness much longer, and will cut much smoother' than any other plane known to its inventor. This modification of form has the further advantage of lessening the weight of the finest cast-steel for making the plane-iron; whereas the comparative weakness of plane-irons of the ordinary make had presented serious difficulties in the way of applying that material, although it is known to be preferable to any other for cutting-instruments.

A fuller account of this invention, coincided with a testimony as to the superiority of the improved plane for use in smoothing box-wood for the use of engravers, is given in the Society's Transactions, vol. ii. pp. 80-85. In the preceding volume of the same work (pp. 83-85) is a description of an ingenious contrivance rewarded by the Society in 1824, to make one plane answer the purposes of the jack-plane, the panel-plane, the smoothing-plane, and the moulding-plane, by having the bottom, or sole, of the plane moveable, and attached to the body of the stock by means of a dovetailed groove. By this contrivance a workman may have several different irons or blades, and any number of different soles, made either flat like those of an ordinary plane, convex or concave in different degrees, either longitudinally or transversely, for planing curved surfaces, or adapted to the form of an ordnary sole plane, and hence it is said to be useful in effecting a great saving both in expense and portability. This contrivance is the invention of Mr. G. Gladwell, who, like the author of the double-bevelled plane, is described as a wood-cutter.

The first attempt to economize labour by means of planing-
PLANTIN, FOSSIL. The progress of knowledge concerning the vegetable which in ancient geological periods covered the surface of our planet has been, until within the last few years, neither rapid nor sure. No small amount of time and patience was required to establish the conviction that organization, not crystallization, was indicated by the wood, leaves, and fruits which abound in the stratification of Europe. Much profound investigation of the natural orders of plants was an indispensable preliminary to the reference of even perfect specimens of fossil plants to their living congeners, and microscopic scrutiny of the minutest tissues could alone determine in fragments of petrified wood the essential characters of primaval trees.

These investigations have been so far advanced by eminent living botanists, that a very great proportion of fossil plants has been satisfactorily referred to the proper classes and great orders, and in some instances to the true families and genera. On this basis, furnished by physiologically botanical grounds, we are in a position to understand the very remarkable speculations—inferences concerning the succession of vegetable life, and the varying distribution of land and sea; and speculations concerning the ancient climate of the surface of the globe, and the ancient chemical constitution of the atmosphere.

Passing over, but without approval, the earlier labours of Steinhausen, Parkinson, and Artis, in England; of Dodoens, who first published the most important doctrine of fossils, in Belgium; of Linnaeus and Agathis, in Sweden, we may safely attribute to M. Adolphe Brongniart the advanced position among the natural sciences which is conceded to fossil botany. Guided by views of fundamental utility at once profound and practically applicable to the subject before him, this zealous naturalist, by personal observations over great part of Europe (1826 and following years) and by communications from many distant places and shores of the world, has established that body of information which is the basis of his two great works, viz. : the 'Frodome d'une Histoire des Végétaux Fossiles,' 1829; and the 'Histoire des Végétaux Fossiles,' which occupied many subsequent years.

A somewhat parallel but less extensive inquiry has since been undertaken in England by Dr. Lindley and Mr. Hutton (Fossil Flora of Great Britain, 1831-36); Géppert (Systema Fossilium Fossilium, 1836), has revised the numerous tribes of fossil ferns; Mr. Bowerbank has collected extensive information concerning the fossil fruits of the London clay, and we are indebted to Dr. Brown, Mr. Witham, Mr. Bowman, Mr. King, and other English naturalists, for a mass of valuable particular tribes of fossil plants. Mr. Morris has combined in his catalogue a summary of the results for the British Islands.

Previous to the year 1839 there hardly can be said to have been specified, excepting in general systems, the types of the particular tribes of fossil plants. In the Frodome of M. Brongniart appeared (p. 219) 501 fossil plants, while the recent tribes were estimated at 50,350. In 1845 Mr. Géppert estimated the known fossil plants at 1795, and the recent species at 80,000. (Reports of the British Association.) Following the classification of M. Brongniart, we find his 501 plants thus divided and compared with living tribes:

Agamia  
Cryptogama cellulae  
Cryptogama vasculess  
Phanogamia gymnostoma  
Phanogamia dicotyledoneae  
Phanogamia dicotyledoneae

It thus appears that the vascular Cryptogamia numerically constituted about half the fossil flora known in 1828, while among living plants they count only as 1 in 30; and the dicotyledonous group, which includes more than half the recent plants, is represented in the stratification of the globe by one-fifth. These results, though modified by later discoveries, are still firmly established. Are we to conclude from this statement, that the vegetation of the ancient world was entirely different in its general organization and constituent classes from the actual flora? Do the plants which we collect in the strata truly represent the entirety of the
Among and great several or actuaries, not siled into the very ferning and assurance. Taking to the extent to the fourth period, we have added the original, and added the general terms Palaeozoic, Mesozoic, &c., in conformity with the views advocated in this work.

Hence it would appear that vascular Cryptogamia had their greatest predominance in the first (Palaeozoic) period; that gynospermuus Phanerogamia acquired their greatest development in the third (Mesozoic) period, while true Monocotyledones probably arrived in the second (Cenozoic) period, and in it approximated to the proportions now actually observed between them in living nature. But it is thought by Dr. Lindley (Fossil Flora, vol. iii. p. 2) that the proportions among the several classes and families of plants preserved in the strata may be very different from those which obtained between the plants when living, because only part of the whole living creation of plants could be expected to resist long immersion in water and the many destructive agencies which are at work on vegetable substances, so as to be preserved in the earth. And this view is to a certain extent confirmed by experiments made by Dr. Lindley, for the purpose of ascertaining the relative conservability of plants belonging to different natural families.

For this purpose, on the 21st of March, 1833, he immersed in a large iron tank full of water, 177 specimens of various plants, belonging to all the more remarkable natural orders, taking care, in particular, to include representatives of all those which are either constantly present in the coal-measures or as undisturbed by the ocean sea, the specimines being placed in the open air, and filled with water as it evaporated, till the 22nd April, 1835. The result of the experiment was then registered in respect of each plant: of the 177 tried, 56 only remained recognisable in water, 121 not to be traced. The numbers were thus proportioned in several natural groups:

- Acrozoic
- Dicyotyledons
- Dicyotyledons polypetalae
- Dicyotyledons monocotylea
- Monocotyledones

Among the Acrozoic the recognisable families were mostly Filices, and Lycopodiacese, these being frequent in a fossil state. Among the Dicyotyledones the recognisable plants were numerous, especially in the Coriaceae, and these abound in a fossil state. With these exceptions, the Dicyotyledonous plants tried were, in general, unable to remain for two years in water without being totally decomposed. The Monocotyledonous plants were found more capable of resisting the action of water, especially Palms and Scatamimous plants, which occur as fossils; ferns exhibited a great power of resisting water, if gathered in a green state, but immersion in water caused their fructification to rot away.

If we were completely assured by observation that the circumstances under which the fossil plants were buried in the sections were the same as those now, we should consider as certain the results under which the above-narrated experiments were made, the inferences from the experiments might be relied on for modifying and perfecting a general view of the ancient vegetation of the globe. But we may not wish to go so far in our assurance. On the contrary, in very many cases there is little room for doubt that the plants were speedily enveloped in mud, and never had time to become fossils. They appear in fact to be a fair sample of the vegetation which actually prevailed on or near to the spots where they are found buried, and were subject to be drifted for that distance by the water in which they were deposited; and arranging the 601 species of fossil plants in periods of geological succession, as well as in groups of natural affinity, arrives at results which appear in the following table. (We have altered the form of the original, and added the general terms Palaeozoic, Mesozoic, &c., in conformity with the views advocated in this work.)
American coal-fields; and thus we find reason to admit a prevalent warm climate in the northern zones of the globe. With these conclusions from the examination of the carboniferous flora, the inferences from the coal-flora agree sufficiently. Substituting coal-flora, which abounds in these, for the lycopsid and carnotids in those, we have a parallel series of results. And warmth of climate appears still to be indicated by the seed-vessels of Piperox, &c., which occur in the London clay. In harmony with these data which are here generalized, into the inference of a warm climate prevailing in the northern zones of the world, even into the Cainozoic periods, is a parallel series of data and inferences derived from the contemplation of the perishable races of animals.

Granted, then, a certain high probability that the great masses of fossil plants — those of the coal-formation in particular — grew in an atmosphere warm and damp, in a climate analogous to the shores and islands of the tropics, we shall not wonder if these vegetable accumulations are of considerable extent. But they are of enormous extent; for coal, itself nothing else than plants accumulated, compressed, and transmuted, is of such thickness, even in some of many workable beds, as to have absorbed the growth of plants on an equal area for hundreds of centuries, if that growth was after the rate it is supposed to have occurred in temperate or even the most favourable tropical regions. In every natural effect time and force are reciprocally involved: if we suppose the ancient growth of plants to have been more rapid than the modern, the time so far allotted may be conceived to be reduced.

M. Brongniart does so suppose the force of vegetation to have varied and to have diminished towards our days, and he speculates on a cause for this, viz. a change of the constitution of the atmosphere by the gradual diminution of the proportion of its contained carbonic acid. That such a diminution of the carbonic acid of the air may have happened, nothing in physical science forbids; that it is not improbable, the late development of air-breathing animals, and the cessation of life on the globe, seems to indicate; and, finally, that it really did happen to some extent at least, after the great period of carboniferous vegetation, may be maintained in a very simple argument. Calculate the quantity of carbonic-acid gas proportioned to the carbon in a given weight of coal: that quantity of the gas, at least, existed in the atmosphere before the fixation of the carbon in the plants which yielded that coal. The whole quantity of coal actually buried in the earth is of course not known, but that which is known, submitted to this calculation, is enough to leave no doubt that previous to the Carboniferous period the atmosphere must have been loaded with carbonic-acid gas, unless compensating processes, of which we have now no example, were contemporaneous in action.

The compensating process now in action is chiefly animal respiration; but we have little or no evidence of the existence of air-breathing terrestrial animals previous to the carboniferous era.

In Morris's Catalogue of British Fossils (published in 1843), the names of 592 species of fossil plants, distributed in 107 genera or families, are given. We propose to enumerate these genera and show their geological distribution so far as relates to the British Islands, according to the classification developed in the Cyclopaedia (Palaeozoic Strata, P. C.; Sylleptic System, P. C.) and exemplified in the article on Fissura, Fossor, P. C. S.

**General Distribution of Fossil Plants.**

Tab. I. In British Strata:—

<table>
<thead>
<tr>
<th>Order</th>
<th>Number of Spec.</th>
<th>Number of Spec.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cyperites</td>
<td>615</td>
<td>105</td>
</tr>
<tr>
<td>Euphorjea</td>
<td>776</td>
<td>105</td>
</tr>
<tr>
<td>Poaceae</td>
<td>279</td>
<td>105</td>
</tr>
</tbody>
</table>

For comparison we add M. Glüpp's statement of the numbers of plants in corresponding strata obtained from all parts of the globe:—

<table>
<thead>
<tr>
<th>Order</th>
<th>Number of Spec.</th>
<th>Number of Spec.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cyperites</td>
<td>615</td>
<td>105</td>

<tr>
<td>Euphorjea</td>
<td>776</td>
<td>105</td>
</tr>
<tr>
<td>Poaceae</td>
<td>279</td>
<td>105</td>
</tr>
</tbody>
</table>

In both estimates the Palaeozoic Plants are more than four times the number of all the other strata. They are chiefly obtained from the coal-measures. Selecting particular groups for consideration, we find some characteristic circumstances of distribution (as in Tab. II.).

</table>
PLASTERING is the art of applying plastic adhesive compositions or cements to walls, ceilings, and such other parts of a building as may require a smooth and even surface, to conceal the roughness of brickwork or masonry, or the timber framing of partitions, floors, roofs, and staircases, in such a manner as to admit of colouring, painting, and other modes of decoration. The business of the plasterer also embraces the formation and fixing of ornamental cornices, centre-pieces, and other ceiling and similar ornaments.

"No art in the economy of building," observes Mr. Hosking, in his treatise on Building, in the seventh edition of the Encyclopædia Britannica, among the most important, is that of the plasterer; and he further remarks that the application of the coat of stucco to the exterior and interior surfaces of houses, and the drawing of the brickwork, is done to produce a similar effect by interposing narrow fillets between them and the laths. The projections and panelled compartments in a plastered surface are provided for by bracketing or cradling down the laths to as nearly as may be the required form.

The first coat of plaster being thus laid, the subsequent operations vary considerably according to the nature of the work, and the number of coats it is intended to apply. If it is to be used only two coats, which, when upon laths, is technically called kind and set, the first coat, or the laying, is levelling with the trowel, and when sufficiently dry, the surface is scratched up or roughed with a bird-brush, and a thin coat, or set, of finer plaster is laid on and smoothed with the trowel, assisted by a wet bristle-brush to moisten such parts as are intended to receive the next coat. In one or two cases, where this method is not necessary, a second coat, the first will occasionally need sprinkling with water to facilitate their perfect union. In better work, where three coats are used, the first coat is laid very roughly, and, while moist, smoothed with their hands; the second coat is applied, as deeply and roughly as can be done without laying the laths bare in any place, to make the second coat adhere the better. This first coat may project a quarter or three-eighths of an inch from the laths, and it is, in this case, called the pricking-up. When it is so dry as to be thoroughly firm, ledges or margins of plaster, called screeds, are formed at the angles, and at intervals of a few feet across the surface, these being very carefully and judiciously levelled. The degree of projection or level which the finished surface should have, in order that they may form gauges for the rest of the work. When these screeds, which are about six or eight inches wide, are set, the intervening spaces or bays are filled up with them, the plaster being very carefully adjusted to the required surface, by means of flat wooden instruments called floaters, made with one or two handles (the latter being called Derby floaters), and stragi-lut-edges, or long pieces of wood, carefully placed to a perfectly straight edge, which are moved backwards and forwards over the work in various directions, to test its accuracy.

When this second coat is nearly dry, it is swept over, and the third coat of a similar proportion, but the plaster made with very fine white lime, is applied as above described, the hand-float being sometimes employed to perfectly flatten and condense it, and, by the aid of occasional sprinkling of water, or by the use of the plasterer's trowel, to be made absolutely hard surface. In performing the like operations upon a brick or stone wall there are some trifling variations, and the first rough coat is called rendering instead of laying. For minute and delicate finishing, we are reduced to the ordinary instruments for painting, and in this case, the plasterer must, however, refer the reader to the articles on the subject in Nicholson's Architectural Dictionary, and to that department of the article Building in the Encyclopædia Britannica which treats on the duties of the plasterer. Ceilings or fine surfaces that have to be whitened or coloured are finished with putty, which is a fine plaster made of the finest powdered lime, macerated so completely as to be held in solution by the water, and forming a delicate paste, which is allowed to evaporate until of the proper consistency for working; but surfaces which are to be papered are finished with a somewhat less delicate variety of fine stuff, with the admixture of a little hair. Surfaces intended for painting are finished, or set, with bastard stucco, which is composed of two-thirds ordinary fine stuff, without hair, and one-third very fine clean sand; and these are finished with the trowel, without the use of the float upon the last coat.

The various modes of finishing stuccoed or cemented surfaces on the exterior of buildings may be passed over with the remark that they are often spoiled by the presence of muddy earth, which, although decayed and readily soluble, is sometimes mixed with the lime and cement, to which causes of failure may be added the occasional presence of argillaceous matter either in the lime, sand, or powder of the cement itself.

"These things ought," Mr. Hosking observes, "to be excepted for a long time, if the work were well protected from..."
access of moisture, which is the grand exciting cause.' 'The paint, or distemper wash on the surface,' he adds, 'is generally sufficient to prevent the rain which may beat against a vertical face from penetrating, especially if the work have been accurately fitted and crowned, so as to make it close and compact; but the evil arises from exposure above, and from the numberless horizontal unfoiled surfaces which are constantly presented,' which receive and detain the water until the earth is saturated, when either from excessive and bottomless rain or from wet weather, which calls in the open air, or warmth calls the vegetative power of its impurities into action, so that it becomes covered with minute vegetation. Hence it insists on the importance of excluding road-drift, (unless that is specially formed by the finest and vegetable matter), and all mud and clay, from the composition of both plastering mortars and mortars for building, although such materials are often used in mixing what the plasterer terms course stuff, under the impression that, as long as it is unctuous and tenacious, its composition is unimportant. He also recommends that care be taken to guard against the effects of wet, not only by providing sufficient shelter, and by frequent painting or distempering, but also by carefully hand-floating and trowelling the upper horizontal surfaces of all projections.

**Rough-cast** is a cheap mode of stuccooing adopted in inferior buildings, where there are good projecting eaves to keep the walls dry, consisting of two coats of course lime and half a coat covered, as soon as a piece of two or three yards is completed, with a semi-fluid mixture of fine clear gravel and strong lime, and washed immediately with an ochreous colour.

Mouldings or cornices are formed by a core or foundation, either of brackets and laths, or in some cases in external work, of projecting bricks and tiles. Very trifling projections may sometimes be supported sufficiently by a few projecting bricks or tiles, a large layer of course stuff and a small layer of stucco applied to the foundation, and to this, when dry, is applied the finer composition of which the moulding is to be formed, as nearly as possible in the required shape. The present form is often given by running the cornice, with the aid of guides attached to the wall or ceiling, or both, a mould formed of a thin board, one edge of which is cut so as to be a perfect counterpart of the profile of the moulding to be formed, and to this, when dry, is applied the closer composition of which the moulding is to be formed, as nearly as possible in the required shape.

**PLENARY** is a genus in the family Malpighiaceae, order Malpighiales, native to the Americas. It is known for its yellow flowers and woody fruit, which is used in traditional medicine.

**PLATENSIS** is a species of flowering plant in the family Caprifoliaceae, native to Europe and western Asia. It is commonly known as the wild rose, and is known for its pink or white flowers and spines.
of drawings of old masters, in chalk, washed, and coloured; the coloured imitations were accomplished by printing with several plates. In 1765 he published a collection of forty-six such imitations in various styles, after drawings by Zoffanie, A. Vandernevel, Rembrandt, Ostade, Van Campen, Vandrick, Van Goyen, Coops, and others, engraved by M. Berthelin, M. Berlio, A. Bloemart, G. Visser, Wouerman, P. Scenredam, Van Mander, Flink, Brouwer, Miera, Terburg, D. Steen, Do Bray, and others. The illustrations together upwards of one hundred imitations of drawings by Ploos van Amstel, and many of these are published in various stages of progress, but very few impressions were taken of any. They are enumerated and described by W. van Eynden, in his "Van Eynden's Kunstkrant," and in "Kunstchronik," by a. Bloemart, in "Lexicon,' a collection of one hundred of Van Amstel's and some additional similar imitations, with a portrait of Van Amstel, was published by C. Jos, in London, in 1821, royal folio; but only one hundred copies were printed, and at the enormous price of forty guineas per copy.

Ploos van Amstel died at Amsterdam, December 20, 1708, and on March 3rd, 1800, his valuable collection, with the exception of the etchings of Rembrandt, was sold by auction, and realized the large sum of 109,406 florins.

When Van Amstel's coloured prints first appeared, his countrymen were pleased at seeing, for the first time, those stones carefully engraved with various plates, and he accordingly drew some impressions in the presence of a deputation of the Dutch Academy of the Sciences at Haarlem in 1768, which decided the question of the priority of his discovery.

(Van Eynden en Vander Willigen, Geschiedenis der Vaterlandse Schilderkunst sedert de heft der XVIII. Eeuw, 1816-42.)

Being the common size, 'grass,' a genus of Grasses belonging to the tribe Festucineae. This tribe is characterized by very short styles, protruded stigmas, and the glumes shorter than the lowest flower. The genus Poa has its glumes rather unequal; the outer pair, with 3-4 nerves, membranous below, scarious at the tip, compressed, keeled, unarmed; the styles terminal. The species of this genus are very numerous, constituting the commonest weeds that follow the migration of cattle. Poa has been so sufficiently treated in the families of the Poaceae, and it is employed in the preparation of feed for various animals.

Thirteen species of this genus are described by Babington as natives of the British Isles. Of these the most common are the P. annua and P. pratensis. The former is perhaps the commonest of British plants, springing up on every neglected spot around the habitations of man. The latter is known by the name of the smooth-walked meadow-grass, and is found in most pasture lands. P. meadow-grass, is also a common grass in shady places. Many of the recent genera of Grasses were formerly referred to the genus Poa.

PILLY, FRANCOIS, a distinguished French engraver, was born at St. Malo, in 1695, and died in Paris, June 1, 1770. He was the pupil of M. Daret, and studied some time in Rome. He adopted the somewhat hard style of engraving of Bloemart in direct crosses, in which he was completely successful: his drawings also perfectly answered the desiderata of an accurately and finely executed engravings. Though Poilly's style is very laborious, there are about 400 prints which bear his name, in which however he was of course assisted by his pupils. His master-piece is the print from Mignard's celebrated picture, now lost, of San Carlo Borromeo administering the Sacrament to the Milanese attacked with the Plague. A catalogue of his prints was published by R. Beauge in 1750; it comprises several after Raphael, including the Viaje a Berellus, the Viaje a Llueye, the large Holy Family in the Louvre, and other Holy Families by Raphael. Poilly died at Paris in 1695. His brother Nicolas and nephew Jean Baptiste Poilly were likewise distinguished engravers, the elder in medallions, the latter in portrait medallions, and in engraving busts of great personages. They both died in Paris.

POINING, in the law of Scotland, is a process for enforcing payment of a debt, against the property of the debtor. It is divided into 'personal poining,' and 'pointing of the ground.' The former is the method by which any security of the kind of interest in land is or may be secured, the latter is peculiar to the holders of real rights over estates belonging to others—to be superior entitled to feu duties or the holders of real securities entitled to payment of the interest due thereon by the possessors of the estate, and to pay themselves. Personal pointing is the most usual form—it is of very frequent occurrence, and is a rapid and effective process. The procedure was simplified and regulated, and was brought within the authority of the sheriff's local court, by 1 & 2 Vict. c. 114.

POISONING, SECRET. When the knowledge of the nature of mineral, vegetable, and animal compounds was less known than at present, it was not uncommon for individuals to owe their lives to the death of persons conversed with poisons, and to keep this a secret for the purpose of exercising a control over the lives of their fellow creatures. The entire ignorance that existed of the means of ascertaining the presence of poisons, or of the means of procuring a cure from them, gave persons other diseases, gave to persons who bad accidentally discovered a poison a great power, and offered a temptation to crime. In ancient history many instances are recorded of persons who became known as poisoners, and are supposed to have been secretly poisoned. Beck in his 'Medical Jurisprudence,' says that 'Theophrastus speaks of a poison prepared from aconite which could be moderated in such a manner as to have effect in two or three years, or at the end of a year or two years; and he also relates that Thrasylas had discovered a method of preparing from other plants a poison which, given in small doses, occasioned an easy but certain death without any pain, and which might be kept back for a long time without causing weakness or corruption. This last poison was much used at Rome about two hundred years before the Christian era.' During the middle ages, many similar poisons were used, and they were greatly employed for the purpose of administering poisons whose powers were known to be strong. There was a general belief that death is obtained, it is supposed, from the aconite, hemlock, and poppy. One of their animal poisons is said to have been the acid juice secreted by a species of Tettihannita mollusce, called the sea-hare, and the apodea of Limenius. They did not seem to be acquainted with mineral poisons.

In modern times secret poisoning has often been carried on to a great extent; although the relation of many of the incidents has been exaggerated. Many instances have been reported of persons being killed by supernatural powers, that it is sometimes difficult to distinguish between the true and fictitious. The aid of poisons appears sometimes to have been resorted to obtain for the powers of the witch and the wizard. A singular combination of poisons was discovered at Rome during the pontificate of Alexander VII. in 1659. It was observed that many young married women became widows, and that many husbands died who were known to have become disagreeable to their wives. Great exertions were used to detect the poisons, when at length suspicion fell upon a society of young wives whose president was an old woman who pretended to foretell future events. Their society at that time consisted of a great number of persons. At length the society was detected, arrested, and every member put to torture, and the old pres- ident, by name Spars, with four others were publicly hanged. A large number of women who lived at Palermo and afterwards at Naples. The poison used by Tofana was the name of Aqua Tofana [Aqua Tofana, F. C.], but its composition was never accurately made known.

The practice of secret poisoning was carried to a great extent in France about the year 1670. One of the most distinguished agents in this business was Margaret d'Aubray, wife of the Marquis de Brétvilliers. She formed an improper intimacy with a villain named Sainte Croix, who taught her the art of poisoning, which she put in practice in order to better her circumstances. For the purpose of ascertaining the strength and effect of the poison, she boiled some lard or tallow, shed the poison, and distributed food to the poor, nursed the sick in the Hotel Dieu, and administered to them her poisons. She poisoned her father and brother, but was last discovered. She was publicly beheaded in Paris on the 16th of July 1676. She left behind her a complete catalogue of all her crimes. The principal poison used by herself and accomplices was the corrosive sublimate. The practice was extended so widely in France that the government thought it necessary in 1679 to institute a court under the title of Chambre de Poison, or Chambre Ardente. The powers of this court were extended, and very shortly after its institution it was suppressed.

Wherever evidence has been left sufficiently positive to admit of an inquiry into the nature of these secret poisons, it
has been found that they contain ingredients well-known at the present day. It is only where the sciences of chemistry and medicine are not sufficiently known, or where they are neglected, that the trade of poisons take place.

In this country we have recently seen an instance at Hapsburg in Norfolk, where, from the neglect of inquiry, a man succeeded in poisoning at different times his wife, two grand-daughters, and a number of his neighbours, amounting in all to 16 or 18 people, and eventually himself without discovery till after his death. Secret poisoning is at the present day practised in Turkey. Mr. Maddox says, that whilst residing in that country he witnessed eight cases, in most of which death ensued within twelve hours, and in all within forty-eight hours. It is not uncommon amongst uncivilized nations. Dr. James, in his account of Major Long's Expedition, says, that 'The celebrated chief, Black Bird, of the Omahas, gained great reputation as a medicine man; his adversaries fell rapidly before his potent spells. His medicine was arsenic, furnished him for this purpose by the villany of the traders.'

(Beckmann, History of Inventions; Beck, Medical Jurisprudence; Adams, Edinburgh Medical and Surgical Journal, vol. xx.)

POISSON, SIMEON DENIS. We regret that we are unable, from want of materials, to give any account of the private life of this very eminent mathematician. He was born June 21st, 1781, in a humble station, and was admitted in 1794 as a student of the École Polytechnique. In his history of this school, records the manner in which the young student, at the age of eighteen, attracted the notice of Lagrange by an improvement in the method of demonstrating the theorem, that in which the latter had laboured in the class, and announced his intention of abiding by it for the future.

Poison never held any political situation, or took public share in anything but education. In 1829 he was Baron, officer of the legion of honour, répétiteur-adjoint and permanent examiner of the Polytechnic School, member of the Council of Public Instruction, and of the Academy of Sciences, April 20th, 1852.

As far as so few words can go, it may be said that the labours of Poisson were directed to the introduction of the use of definite integrals into all branches of mathematical physics, and the extension of the various branches by their means. There is nothing out of which to make a popular reputation; the successes of Poisson are all purely mathematical, and none but the mathematician can as much understand the description of them.

The greater part of the writings of Poisson are contained in various periodicals, particularly the Memoirs of the Institute, the Journal of the Polytechnic School, the Annales des Sciences Mathématiques, and the Mémoires de l'Académie des Sciences. There is hardly any subject on which they do not treat, and almost always with decided success; electricity, magnetism, heat, gases, capillary attraction, gravitation, the pendulum, &c. &c. &c. In no branch of science does the mind of a mathematician of our time manifest more of the analytic and synthetic in a well-written paper by Poisson. His object was to leave no branch of physics unexplored by aid of the new and powerful methods of investigation which a school yet more modern than that of Lagrange and Laplace had added to the pure mathematics. Towards the end of his life he began to collect his scattered memoirs into separate works, with the additions which his subsequent researches had necessitated.

Poisson's separate works are—1. 'Traité de Mécanique,' Paris, 1811, 2 vols. 8vo.; second edition, Paris, 1833, 2 vols. 8vo. Perhaps this is the best elementary work on the branch of mathematical physics which exists, considered as an introduction to the use of modern analysis. An English student should read it with some of our own writers, who abound in examples, but have not the analytic and synthetic in the same degree. 2. 'Traité de l'Action Capitale,' Paris, 1831, 4to. The principal distinction between this theory and that of Laplace, physically speaking, is the consideration of the variation of density which takes place at the surface of the capillary column of fluid. 3. 'Théorie Mathématique de la Chaleur,' Paris 1835, 4to. The data from which Poisson starts are derived from the experiments on the nature of heat, made subsequently to the time of Fourier, his pupil; in this branch he is the successor of de l'Action Capitale, Paris, 1831, 4to. This is, in fact, a treatise on the theory of probabilities, with especial reference to its application to matters of evidence, particularly of the judicial kind. With the exception of some partial substitution of definite integrals for series, there is little advance, mathematically speaking, upon Laplace; but the application to questions which he had never met, in a new point of view. Accordingly, Poisson has, with great judgment, made the application the heading of the whole work, though it occupies only the quarter of its space. It is said that Poisson was unable to properly finish this task, and several remarks, 4. 'Polanista' from 1492, many, and vulgar, unequal; stamens numerous and unequal, a genus of plants belonging to the natural order Caryophyllaceae. It has 4, sometimes 5, sepals, 4 petals, a small torus; silique sessile within the calyx or hardly stipitate, terminated by a distinct style. P. leontandra has a stem covered with viscid glandular hairs, 3 to 5 foliaceous leaves, the leaflets oblate, conicus, or oblong subacute, scarcely longer than the petiole. The stamens are about 10 in number. The silique terete striated, rough with glandular horns, sessile and acuminate. It is native of the East Indies, and is used in Cochin China as a counterirritant in the same way as staphisagria in Europe, and as a vesicant. The root is used as a vermifuge in the United States of America. P. flavens is a plant bore with glandular hairs; it has trifoliolate leaves, elliptical oblong leaflets, from 8 to 12 stamens, oblong silique narrowed at the base, glandularly mucronate and pubescent. It is native of North America, and is employed as a mouse poison. 5. 'Polarization,' (Circular Polarization, C.F.C.S. Eclipse, Polarization, P.C.S.)

Polarization, Moveable, is the name given by Biot to a supposed oscillatory movement of the molecules of polarized light in passing through a plate of doubly refracting crystal; and the hypothesis was proposed in order to account for certain variations of tint observed in the coloured images produced by the ordinary and extraordinary pencils of light. This philosopher assumed that, in permanently polarized light which has been transmitted through a doubly refracting medium, the molecules composing the ordinary pencil or ray have their axes at right angles to those of the molecules which compose the extraordinary pencil; and M. Arago having observed that a polarized beam of light is not capable of transmission by a millicolour, he supposed that the application of a magnetic or electric current to the plate would cause a certain depth, depending on the degree of attractive or repulsive power to which the particles are subject in the medium; and he conceived that, previously to being in that state, the axes of the molecules assume, in a series of alternations, first one and then the other of two particular planes of polarization.

Consistent with the phenomena of the colour seen in polarized light are analogous to those of Newton's rings, the ordinary and extraordinary rays giving rise to colours corresponding to those of the rings seen after transmission and reflection in air.

The phenomena of transmission and reflection in glass, and the phenomena of refraction and reflection in other media, are in a way parallel to the effects observed in the passage of light through the plate of sulphate of lime, the alternate polarizations take place at intervals equal to those between the terms in a corresponding progression, these intervals being, however, much greater than those of Newton for the same reason; viz. as the rays are at right angles to the plane of the polarizer. Furthermore, the axis of polarization is not only a depth represented by $e$ in the crystal, the molecules are conceived to be polarized in the original plane of polarization; between the depths represented by $e$ and $2e$ they are supposed to be polarized in a plane making with the original
plane of polarization an angle equal to that which the two axes of the biaxial crystal make with each other; within the next depth, that is between 2' and 3', they appear to be again situated in the plane, and so on.

In the same kind of crystal the values of $\epsilon'$ are supposed to differ for the different kinds of light, but the limits of the oscillation are the same for all particles whose motions are in the same direction and the oscillatory action is supposed to cease when the luminous particles quit the posterior surface of the plate and pass into the air, or enter into any other medium which has not the property of double refraction.

The phenomena presented by mica, beryl, rock-crystal, Iceland spar, and many other crystals, are the same as those presented by sulphate of lime, except with respect to the thicknesses at which the periodical variations of the tints take place. The last of these depend entirely on the laws explained by the hypothesis of a movable polarization: the oscillations, however, do not take place on each side of a line bisecting the angle between the two axes of the biaxial crystal, but on each side of the polar towards which the planes of the pencil ordinarily refracted by the plate would be turned if those particles had acquired a permanent polarization.

Though Biot's hypothesis of movable polarization has been found capable of explaining most of the phenomena of polarized light, both that in which the incident pencil consists of parallel rays and that in which, the rays being convergent, coloured rings (Polarized Rings, P. C. S.) are produced, yet it is known to them in many respects to be inadequate. The necessity of the presence of a definite section of crystal to produce the plane of polarization in plates of crystal may be satisfactorily explained on the principles of the undulatory theory: thus, suppose a polarized ray to be incident perpendicularly on the plate, having its vibration plane inclined to the plane of primitive polarization in a certain angle; that ray will then be resolved into two, the vibrations of the aetherial molecules in which are respectively performed in the principal perpendiculars to it. Now, if the thickness of the plate be such as to render the difference between the lengths of the paths of the rays within the crystal equal to an exact number of vibrations, the rays will emerge from the plate in crystal secundaries; in this case the ordinary and extraordinary rays being exactly equal in thickness, they will not destroy each other, and it will be found that the resultant ray, at emergence, is in respect of intensity and polarization, similar to the incident ray. But if the difference between the lengths of the paths of the rays within the crystal be an exact odd multiple of half an undulation, the waves at their egress will be in discordance, and the resultant ray, at emergence, will be another polarized ray in a plane making an angle with the plane of the incident ray equal to twice at which the principal section of the plate is inclined to the plane of primitive polarization.

POLARIZED RINGS. Between the year 1812 and 1816 several important properties of polarized light were discovered by philosophers in England, France, and Germany, and of these the formation of the coloured rings which are seen when polarized light passes through plates of a doubly refracting crystal, are the most remarkable.

As early as 1811 M. Arago and Biot had observed the variations in the colours of images, which take place when polarized light is transmitted through plates of mica; and in 1812 Dr. (Sir David) Brewster had made similar observations with agate, mica, and topaz. But the British philosopher vastly extended this branch of optics by his discovery of the systems of rings, which may be seen both in bi-axial and uni-axial crystals when conical pencils of polarized light are transmitted through them; and his experiments, with those of Young, Wollaston, and Sir John Herschel, in England, have afforded ample materials for determining the laws of these phenomena. In 1813 Brewster observed circular rings in ruby, emerald, and beryl; in the following year the like were witnessed by Dr. Wollaston in Iceland spar and in 1815 they were seen by M. Biot in France and by Dr. Sebeck at Nürnberg.

In order to understand the manner in which the phenomena may be observed, it will be convenient to imagine that the light is transmitted through a plate MN (Fig. 1) which is made of two plates of glass either parallel or inclined to the horizon; (a plate of obelidian or a pile of glass plates placed one on another may be employed) its posterior surface being blackened; and let ABC be the axis of a slender pencil of light from the clouds or from a lamp surrounded by unpolished glass, and let it fall on MN at an angle of incidence equal to 50° or 45°, the reflected pencil, of which let AB be the axis, will then be polarized in the plane of reflection SAB, which may be called the plane of primitive polarization; and in this state let it fall on PQ at an angle of incidence: from B let it be reflected to the eye of the observer, suppose at C. The plate PQ should be attached, as in the figure, to the surface of the blackened plate, and, for convenience, let the block be a triangular prism of which the plane PD is horizontal and the plane EDQ vertical; the block should be capable of being turned on an axis as BIF in the direction of the ray AB produced.

Agreeably to the hypothesis of Fresnel the vibrations of the aetherial molecules, when light is polarized, take place perpendicularly to the plane of polarization; therefore, if the plates MN and PQ are disposed as in the figure, so that the course SABC of the ray is in one plane (suppose vertical) and no object is placed in the direction of the pencil AB, the vibrations will take place after reflexion from PQ, exactly in the same manner as they take place between the mirrors, and the spectator will have a strong perception of the reflected light. But if PQ be turned on the axis ABF, the perception of the reflected light diminishes; and when the base PD is perpendicular to its first position, in which case the planes SAB and ABC are at right angles to one another, the vibrations are destroyed in consequence of a polarization with respect to the plane ABC', so that the eye at C has no perception of the reflection.

Now, let a thin plate of Iceland spar, ruby, emerald, or other uni-axial crystal cut with parallel surfaces, each perpendicular to the axis of the primitive crystal, be placed as at K in the direction of the pencil AB, the former state of the plate of light will be partially restored; and an eye at C receiving the pencil through a small aperture, there will be seen in the field of view a number of concentric circular rings of a white and greenish hue, of different colours produced by the birefringence of the crystal. The colours in the succeeding rings are arranged in the like order till the rings cease to be perceptible, the cross remaining black.

The phenomena may be observed with equal or greater facility by placing the plate of Iceland spar or other uni-axial crystal between two plates of tourmaline parallel to each other and to the plate of spar, and observing the lights directly through them; the plate of tourmaline which is farthest from the eye polarizes the light transmitted through it as the plate MN (Fig. 1) polarized it by reflection, and the plate nearest to the eye, having its axis perpendicular to that of the former plate, performs the same office as the analyzing plate PQ, when the surface of the latter is perpendicular to MN. The plates of tourmaline should be cut with their surfaces perpendicular to planes passing through, or parallel to, the axis of the natural prism; and what is called the axis of the plate is any line drawn on either of its surfaces parallel to the axis of the prism.

In 1813 Dr. Brewster observed that certain crystals, when polarized light was transmitted through them, exhibited two distinct systems of rings; and his first observations were...
made on blue topaz: a plate of this mineral being placed, as at 1 K (Fig. 1), and the analyzing plate PQ being turned round on BP till PD was at a vertical position, that is, all the plane ABC was at right angles to SAB, there appeared a system of rings, apparently elliptical with a rectilineal band quite dark in the direction of the major axis: the colours of the rings appeared constantly to those of the former series, or, apparently similar to those of Newton’s rings when seen by reflection. But, turning the plate PQ on BF as an axis 90° further, or 180° from the position in the figure, the series of rings appeared with colours seemingly complementary to those of the former series, or, apparently similar to those of Newton’s rings seen by transmission. But, turning the plate PQ on an axis BF perpendicular to BF in the plane SAB of primitive polarization, there was found a position in which, by the reflected ray BC, there was seen a system of oval rings similar to the first. Dr. Brewster observed the like phenomena with plates of mica, nitre, sulphate of lime, &c.; and this led to the discovery that, in such crystals, there are two axes along which there is no double refraction. These are the optic axes of the crystal, or, as they were called by Brewster, axes of no polarization. In different crystals these axes have different inclinations to one another; in mica they make with each other an angle of 45°, in nitre much less; and a plate of crystal cut for the purpose of exhibiting the double system of rings should have its faces cut perpendicularly to a line bisecting the angle formed by the optic axes.

Now, if a plate of any biaxial crystal, as mica, nitre, &c., be placed as at 1 K in the direction of the polarized ray, and be turned so that one of the optic axes is coincident with that ray; the analyzing plate PQ (Fig. 1) being also turned so that the reflected ray BC may be in a plane at right angles to SAB, there will be seen, about a dark point P (Fig. 3), representing that in which the crystal intersects the field of view, a series of oval rings brightly coloured and divided unequally by a dark band MN. A like series of rings about a point corresponding to P, with a dark band like MN passing through that point, will be seen if the plate of crystal be turned so that the other optical axis is in the direction of the polarized ray AB. And when the angle which the optical axes make with one another, or with a perpendicular to the surface of the crystal, is small, as in nitre, both series of rings with their bands may be seen at the same time.

When a plane passing through AB, Fig. 1, and the two optic axes of the crystal is made, by turning the plate of crystal on the ray AB, to coincide with the plane SAB of primitive polarization, the dark curves passing through the two polar points P and P’ (Fig. 3) become one straight line MN; the coloured rings come together as in the figure and are crossed by another dark line as MN passing through B the centre of the light ring of the plate (P. Fig. 3) appearing at every quarter revolution of the crystal plate 1 K (Fig. 1), on the axis AB; and by actual measurement the coloured rings are found to have the form of lemniscates, whose principal property is that two points of a line drawn from the points P and P’ to any point in each curve is constant.

The general equation of Bernoulli’s lemniscate is 
\[(x^2 + y^2)^2 - a^2(x^2 - y^2) = 0\]
in which \(a\) is equal to half the axis \(m\) of the particular curve.
time two lines or bands traversing the coloured field of view at right angles to one another, in which the light vanishes; and thus there produced the appearance of a dark cross, the point of intersection being in the centre of the field, or where the latter is traversed by the ray AB.

When \( \omega = 0 \), or the axes of polarization in AB and BC are coincident, the expression (c) becomes

\[ \alpha^2 = (1 - \sin^2 \theta) \frac{4 \sin^2 \theta}{R} \]

(c) which when \( \omega = 0, 90^\circ, 180^\circ, \) and \( 270^\circ \) becomes \( \alpha^2 \), a maximum: hence the coloured field of view will be traversed by a white cross, twice as long at right angles to one another.

If \( \alpha \) have other values, the expression (b) or the density of light will vanish when \( R = 0, R = \pm A, R = 2A, \) &c. The equivalent of \( B \) containing, as a multiplier, \( \sin^2 \theta \); (1 being the incidence of a ray on the crystal after diverging from A; or the angle which, as above mentioned, a ray from A makes with the axis AB) one giving successively to R the values 0, \( \theta, 2\theta, \) &c., it is found that \( \sin \theta \) has corresponding values propor-
tional to \( R = \frac{2A}{\theta}, \frac{5A}{\theta}, \frac{8A}{\theta}, \) &c.; (T being the thickness of the plate of crystal) and since the expression (b) has the same value, and vanishes or is a maximum, for all rays whose angles \( \phi \) of incidence in the conical pencil diverging from A are the same, it follows, that about the axis of the field of view, there are bands whose radii have the proportions of \( \sqrt{2}, \sqrt{3}, \sqrt{4}, \) &c. The expression (b) is a maximum

\[ R = \frac{1}{3}, \frac{2}{3}, \frac{3}{3}, \frac{4}{3}, \] and when \( \sin \theta \) has values propor-
tional to \( 1, \sqrt{3}, \frac{3}{\sqrt{2}}, \sqrt{4}, \) &c.; and it follows that,

about the axis of the field, there is a series of bright rings whose radii have the proportions of \( \sqrt{1}, \sqrt{3}, \sqrt{4}, \) &c.

The expressions (b) and (c) added together produce \( \alpha^2 \); hence the tints of the several rings formed when the planes of polarization in AB and AC are coincident are complementary to those which are formed when those planes are perpendicular to one another: for the dark rings have radii which are proportional to \( \sqrt{2}, \sqrt{3}, \sqrt{4}, \) &c., while the dark rings have radii proportional to \( 1, \sqrt{3}, \sqrt{4}, \) &c.

For the investigation of the phenomena of the rings seen (as in Fig. 4) when AB is a bi-axial crystal having its surfaces cut perpendicularly to the plane passing through the axis; and also for the phenomena presented when a plate of crystal, uni-axial or bi-axial, is so cut that the surfaces are not perpen-
dicular to the axis, or to the plane passing through the two axes, see Airy’s Tracts (Undulatory Theory). The reader is referred also to Sir David Brewster’s Treatise on Optics in the Edinburgh Encyclopædia, and to Sir John Herschel’s Treatise on the Study of Artificial Starlight.

POLEMONIUM (polémonion of Dioscorides), a genus of plants, the type of the natural order Polemoniaceae. It has a campanulate 5-cleft calyx, a rotatory corolla, and a short tube with a 5-lobed smooth cap. The seeds are at times inserted in the throat of the corolla with filaments dilated at the base, bearded in a continuous ring, and nearly closing the throat, and incumbent anthers; a roundish capsule with membranous crustaceous valves, covered with the permanent calyx and many-seeded seeds; the seeds oblong, trigonal, and filled with albumen; the radicle twice as long as the cotyledons. The species are erect herbaceous plants, with alternate unequally pinnate leaves; the flowers terminal, bracteate, arranged on panicled corymbus, with blue or white corollas. About twelve species have been described, most of them being cultivated and known in our gardens as Greek Valerian.

P. cordatum, common Greek Valerian, Jacob’s Ladder, or Ladder of Heaven, has a glabrous stem, pinnate leaves, ovate lanceolate acuminate lacinias, the segments of the calyx ovato ovato or elliptic, lanceolate, pointed; the panicule downy, glabular. The flowers on one or two feet high, the two ter-
ners, the flowers numerous, bright blue or white, somewhat drooping. It is a native of Europe and America, and is found in Great Britain, but is a rare plant. A great number of varieties have been raised, some of which are of great beauty and useful in our gardens, and will grow in any common garden soil, and may be readily propagated by dividing the root or by seed. Although deriving its generic name from the Polemonium of Dioscorides, the plant so called is not the species described of that plant, and Fras refers it to Hypericum olympicum. Great virtue were attributed to the antient Polemonium, and these were transferred to the modern plant; but neither the antient nor modern plant possesses any active medical properties. Slight astrigency is the only property possessed by any of the species of Polemonium. (Fras, Synopsis Plant. Flor. Class.); Don, Garden’s Dictionary .

POLICE. In the Scottish large towns have separate police statutes, by which the management and control of the system is put into the hands of elected commissioners. The act of 1846, &c. is a general act authorizing the constitution of police districts, or a portion of them, may be adopted, so as to become law, by any royal hurch, hurch of regality, or hurch of bony, at a meeting of a specified number of ten- pound households, or other local associations. The act provides for the election of commissioners with power of management and control, by the same class of persons who are entitled to decide on the adoption of the act. By 2 & 3 Vict. c. 65, called the Rural Police Act, the commissioners of empty or any county are authorised, at a meeting called on requisition by ten of their number, to assess the county for maintaining a const-
estation force. The act directs the commissioners to publish annual accounts of receipt and expenditure. The system is co-operative with the expenditure of an old established fund for rural police purposes, called the ‘Rogue Money.’

POLLAJUOLI, PIETRO ANTONIO, was distinguished Florentine artist and sculptor of the fifteenth century; they were the sons of Jacopo del Pollajulo. Piero was the pupil of Andrea del Castagno; Antonio was the more distinguished of the two. He was summoned to Rome, and assisted him in the celebrated gates of the baptistery of San Giovanni; he became also a famous goldsmith, and was as such without a superior in Florence. Mase Finiguerra was his contemporary, and was greatly assisted by him in his paintings together; the best of them, says Vasari, is the Martyrdom of St. Sebastian, painted in 1475, in the church de' Servi at Florence. St. Sebastian was painted from nature and is one of the best figures that had been painted up to that time; it is engraved in the Etruria Pittrice of Lastrini. Anto

nio is said to have been the first artist who studied the dead subject for the design. Antonio Pollajulo was invited to Rome in 1484, after the death of Sixtus IV., by Innocent VIII., and he made the monuments of Sixtus IV., and of Innocent VIII.; that of Sixtus, in 1493, is now in the chapel of the Sacrament in St. Peter’s; the monument of Innocent is also in St. Peter’s. Antonio was also a medallist, and he engraved three or four plates, which are extremely scarce.

(Vasari, Vite de’ Pottori, &c., and the notes to Schorn’s German translation; Rumohr, Italianische Forschungen; Cicogna, Storia della Scultura; Baldinucci, Notizie dei Professori del Disegno, &c.)

POLLAJUOLO, SIMONE DEL, or Simon Masi, a distinguished artist and sculptor, celebrated for his ability in relating stories, was born at Florence in 1454. He was related to Antonio del Pollajulo, and lived with him some time at Rome. He is chiefly distinguished for the Palazzo Strozzi, one of the noblest works of art of Florence; it was commenced in 1489 by Benedetto da Maiano, but was completed by Cronsacca, and the great corsoic or estalliture and the court in the interior are from the designs of Cronaca. The ironwork and the beautiful lan-
terns are by Niccolo Grosso, commonly called Caparra, a nickname which was given to him by Lorenzo de’ Medici on account of his always persisting in being paid before he deliv-
ered his work; Caparra was a money receiver or deposito of his own money.

Grosso was the most celebrated smith of his time.

Cronsacca built also the great council-hall for the Signoria of Florence, which was afterwards enlarged and embellished by Vasari; the church of San Miniato al Monte, the convent Dei Servi, and the Sacrity of Santo Spirito. He was a fol-
lower of Savonarola; he died in 1569.

(Vasari, Vite de’ Pottori, &c.; Gage, Carteggio Inedito d’Arte. &c.)

POLLOK, ROBERT, a poet and miscellaneous writer, was born at Muirhouse, in the parish of Eglashan, in Ren-
freshire, in 1789. He studied at the university of Glasgow, and afterwards entered the course of natural philosophy necessary to fit him for a charge in the United Secession Church, of which he became a licentiate in 1827. His principal work, which is in some respects auto-biographical, speaks of the solitude of his abode, and describes the simplicities of the scenes in which he passed his youth.
He was a hard student, and appears to have been early en-
dowed with a strong ambition to create for himself a per-
manent name in literature. In his own words—

"The voice be heard, read, thought worth, and
With old heads of honorable name.
Measured his soul severely; and looked
To fame, ambitions of no second place.

Just before he received his licence, he had finished the
poem on which his literary reputation rests, 'The Course of
Time.' A work so ambitious, from the hands of a country
student attached to a small body of dissenters, was not likely
to produce any impression on publishing circles. It was
nevertheless shown to Professor Wilson, of Edinburgh, as a
curiosity, and he was astonished to discover in it great poetic
power. In deference to his recommendation it was published by
Mr. Blackwood, of Edinburgh, and speedily passed through
several editions. Its flight of genius was a novelty in the
class of evangelical religious literature to which it belonged,
and besides pleasing those who are partial to that class of
religious literature, it was a boon to many who are inclined
to read religious books, but are repelled by their general dry-
ness and insipidity, while it was warmly admired by the
literary world at the time. Mr. Pollok is a poet of simple
imagination, for his plan is on a level with Milton. After the novelty
of such a phenomenon had however passed off, the book became
neglected by purely literary readers; and at this day it may be
said that it is highly regarded by religious and too
insipidly by the literary world. It is a work of great
power, but meagre fancy. It has a considerable amount
of sentiment deeply tinged with religious asceticism. Many
sentiments are spun out or repeated, and the interest frequently
flagging. The work exhibits a great command of the English
language and a power of terse rapid melodious diction.
Pollok's mind was evidently imbued with 'Paradise Lost,' and
he follows Milton often too closely in his diction. Before the
publication of his poem this interesting young man
had undertaken his constitution by excessive mental labour,
and he scarcely lived to see its success. On the recommendation
and through the assistance of his friends he was preparing for
a journey to Italy. The simplicity in which his family was
brought up, may be imagined from the circumstance that his
sister, who was to accompany him, obtained a certificate
of good character from the minister and elders of her parish,
believing that such a testimonial was all the more necessary
as they were about to proceed to the land of graven images.

The disease had however made too great progress to admit
of his leaving Scotland, and he died near Southampton on 15th
December, 1897.

POLYCARPON (from σωλή, many, and ἀσπασσός, a seed or
fruit: seeds numerous), a genus of plants belonging to the
natural order Polygonaceae. The sepals of the corolla, attach-
ing at the base, the petals 5 and emarginate. The stamens
from 3 to 5; styles short and 3 in number. The fruit is 1-
celled, 3-valved, and many-seeded capsule.

P. peltatus has numerous bright crimson petals, lanceolate
leaves in fours, and the leaves on the branches
opposite. In young plants the leaves are often all opposite.
It is a native of the coasts of the south-west of England,
of Ireland and the Canaries.

There are two other species of Polygonon: P. dinic-
ides, an inhabitant of Europe, the Cape of Good Hope, and
Holland; and P. pepliods, a native of Styria and France.

The seeds of the annual species require only to be sown in
the open border in spring. The last species, being perennial,
should be grown in a small pot, and placed among other
alpine plants.

P. peltatus (from σωλή, many, and ἀσπασσός, a seed or
fruit: seeds numerous), a genus of plants belonging to the
natural order Polygonaceae. It has a 5-petalled corolla, from 3 to 5
stamens, and from 2 to 3 styles; a 1-seeded trigonous or compressed nut,
inside curved embryo, the cotyledons not contorted. This
is a very extensive genus, containing the knotgrasses, bistortas,
pea-sedges, great duckweeds of our own waysides, fields, and
gardens. They grow in almost any soil, some being aquatic,
and others flourishing in sandy sterile tracts

P. bistorta, Snake-weed, has a dense spike, ovate subcordate
leaves, the radical leaves with winged foot-stalks, the sta-
mous half as long again as the perianth, the nut tritqueotous,
its faces ovate, smooth. The calyx is rose-coloured and
deply five-lobed, obtuse, and spreading. The fruit is black
and shining. This plant is one of the most showy
of our table herbs, its root contains tannin and gallic acid in
abundance; a decoction of it is employed in gleet and
leucorrhoea as an injection, as a gargle in sore-throats, and as a
lotion for the eyes. It is distributed with exceptional abundance.
It has been used combined with gentian in intermitents.
It may also be employed in passive hemorrhages and diarrhcea.

P. sativum has a dense ovate cylindrical spike, stalked
ovate or heart-shaped leaves, a compressed nut, 6 stamens, and a
creeping root. The flowers are of a bright
red colour. It is a native of England in ponds, ditches, and
ponds. It is a fine showy plant, but one of the most
diuretic, and it is distributed from land to
or drained lakes and marshes. The subaquatic stems at
every joint, and extend to a surprising length, rising through
the soil, and bearing some resemblance to sarsaparilla, and
according to Cotta and Willmet they are substituted for this
by the herborists of Nancy; these authors also report
that the apothecaries and druggists of Lorraine give it the
preference.

P. hydropiper, the Water-Pepper, has drooping filiform
interrupted spikes, lanceolate wavy leaves, glandular perianths,
a large compressed nut, its faces ovate, acute, and of a
purplish crimson colour. The black color is a hot acrid plant, and is reputed to be a
powerful diuretic, but it loses its activity by drying,
and therefore requires to be used in a fresh state. It dyes wool
of a yellow colour. The seeds, according to Bulliard, are used
in some of the French medicines instead of pepper. The
leaves are so acrid as to act as aperient. It is native of
England in ditches and wet places.

P. anisoides has from one to three flowers together, axillary
lanceolate leaves, or elliptical plane stalked lanceolate acute
seeds, with few simple simple nerves at length by growth
becoming tor, a tritqueotous nut with raised points shorter
than the perianth. Its numerous seeds supply abundant food for small
birds; they are said to be excellent aphatic. Thomson says
that in Japan a blue dye is prepared from this plant.
There are many other species of Polygonon, natives of Great Britain
and other parts of the world, but too numerous for description here.

P. tincturis is cultivated in France and Flanders on account of
the fine blue dye extracted from it. The seeds of P.
barbatum are used in medicine by the Hindu practitioners,
and are said to ease the pain of piping in the colic. The
leaves of P. hispidum are said by Humboldt to be substituted
in South America for tobacco; and P. anti-haemorrhoidale is esteemed in Brazil on account of its astringency in baths,
poultices, &c. &c. The juice, as well an infusion of the ashes
when burnt, is employed by the Berio in the clarifica-
tion of syrup and the condensation of sugar.

P. Fagopyrum, the Buck-wheat, is now referred to Fagopy-
rum esculentum. [FAGOPYRUM, C. B. S.]

(Linn.) is a scented annual growing in Flanders.'s Manual Brit.
Bot.; Burnett's Outline of Botany; Lindley's Florida Medica.)

POLYPODIUM. [FILICES, P. C. S.]

POLYPODIOGN (from σωλή, many, and ἔπειτος, a beard), a genus
of grains belonging to the tribe Agrostidæ. It has serrous
equal grains, each furnished with a long seta from
just below the emarginate summit. The pappus are shorter
than the grains, the outer ones usually curved from below
the summit.

P. moniales has the setae more than twice as long as
the rather obtuse grains. It has a fl Learning root, a stem
from a foot to foot and a half high, the leaves lobed silky panicle
often two inches long. The grains are linear and hairy. It is a very beautiful grass, and is a native of Great Britain
in salt marshes. It is the Deserbius (fox-tail) of Theophras
tus, Hist. Plant. 7, 17.

P. littoralis has its setae equaling the acute grains.
The root is somewhat creeping, the stem a foot high, the
panicle close lobed and purplish. The grains are linear
and lanceolate. It is a British species and is found in
muddy salt marshes.

(From BAILEY'S Manual of British Botany.)

POLYTECHNIC SCHOOL. This Institution, which
has been established in the ion of pure and physical science, originated, at the time of
the great revolution in France, with one of the representatives
of the people, named Prieur (le Cote d'Or), who being a
member of the Committee of Public Safety, and charged with

Digitized by Google
the duty of superintending the practice of the arts which relate to the service of the country, introduced a plan for the establishment of the school to one of the particular committees which had been appointed by the National Convention. In consequence of a report made by Fourcroy in the name of the committee, addressed to the Directory, under the designation of "École centrale des Travaux publics," was, by a decree of the Convention, dated 21 Ventôse, An II. (Feb. 18, 1794), directed to be formed; and the charge of organizing it was wholly committed to Fourcroy, who carried on a correspondence with the Comte de Moivre: the first, in particular, was appointed to determine the branches of science which were to constitute the course of study.

The school was to consist of 400 pupils, who were to be admitted on undergoing, satisfactorily, an examination respecting their knowledge of the elements of arithmetic, algebra, and geometry; and, after remaining three years at the institution, during which time they were to be instructed in the higher branches of mathematical science, they were to receive appointments for the posts of civil or military engineers.

The course of instruction was divided into two principal branches: the first consisted of mathematical analysis with its applications to geometry and mechanics; and to these were added a course of descriptive geometry [Moxor, P.C.], with applications to statics, anatomy, and fortification; the second branch consisted of chemistry and natural philosophy. A building in the Rue St. Geneviève was chosen, and the school was divided into classes, each consisting of persons who carried on their studies in a separate hall, during the hours of the day; at certain times, however, they attended lectures in the theatre of the institution; and on two days in every ten they were employed in physical or chemical experiments.

They were required to execute all drawings relating to the subjects of their studies, and to perform experiments with their own hands, conformably (as is stated in the programme) to the method followed in the school formerly existing at Mézières, for military engineers; and in the school of chemistry and mining at Schénmitz in Hungary.

Such was the origin of an institution with respect both to the talents of its professors and to the contributions which science has received from so many of its écoles, France may be justly proud; and it is worthy of remark that it was formed at a time when some of the most influential men in the government of the country proposed to put all the learned men to death, and to annihilate science as being injurious to the interests of the new republic.

Outlines of the lectures delivered by the professors during the first year were published in 1796 in a volume forming the first of those which constitute the "Journal de l'École Polytechnique," and among these are one on stereotomy, by Monge, on architecture by Baltars, on fortification by Dobenheim, on chemistry by Neveu, by Fourcroy, and on analysis by Freny.

In the course of the same year, 1796, the National Convention decreed that the "École centrale des Travaux publics" should be called the "École Polytechnique," and that the new regulations were made concerning the subjects in which the candidates for admission were to be examined. In mathematics there was required a knowledge of algebra, as far as the resolution of equations of the first degrees, their application to geometry; the summation of series; trigonometry, and the properties of conic sections. For the convenience of persons residing in the provinces, the examinations for admission to the school were appointed to be held, at the same time, at towns situated in different parts of France; the municipal authorities of the towns were to be present, and the examinations were to be conducted by daily committees of professors, who had served in the armies of the republic during three years should be admissible till they were 26 years of age. The pupils, in general, had then the rank of serjeants of artillery, and their daily pay was 98 centimes (99 pence). The military uniform was continued, and on the margin of the buttons were the words "École polytechnique;" some alterations were made in the mode of conducting the examinations; and a council was appointed for the purpose of attending to the state of the school, and also of suggesting measures for its improvement.

When Bonaparte became emperor, in 1804, the school was again remodelled, and Monge was replaced at its head; it then acquired the name of École centrale des Travaux publics, and it received an organization completely military. While that extraordinary man governed France the institution may be said to have been in its most flourishing state; and the subjects of the course of study were then arranged under the heads, as follow:—Mathematical analysis; mathematical analysis applied to geometry; descriptive geometry; mechanics; machinery; natural philosophy; chemistry; geodesy; geology; by Monge on perspective, topography; the theory of figures and landscapes; grammar and the belles-lettres. At that time also, the following were the subjects a knowledge of which was required for admission to the school:—1. Arithmetic, with an exercise containing the resolution of equations of the two first degrees—indeterminate equations of the first degree; the compi-
tion of equations—demonstration of the binomial theorem—the method of commensurable divisors, and that of equal roots—the resolution of numerical equations by approximations, the elimination of unknown quantities in equations of any degree having two unknown quantities. 3. The theory of proportion—progressions and logarithms. 4. Elementary geometry and plane trigonometry. 5. Part of the conic sections. 6. Distribution of foci and conics, presented by equations of the first and second degrees with two unknown quantities—the principal properties of conic sections. 7. Statics demonstrated synthetically and applied to the treatment of the machinery, the anchor, the balance, the lever, and the axio, etc. The candidates were also required to translate part of a Latin author in prose and give a grammatical analysis of French passages. 9. To come to the compasses and a geometrical figure which the examiner might indicate. 10. To draw and shade, with pencil, a figure from a given model.

In 1814 the students of the school took a share in the defence of Paris, and even assisted in serving the guns directed against the allies. On the restoration of the Bourbon family, the school was for a time suppressed; but it was afterwards revived, and it then received the title of 'Ecole Royale Polytechnique,' which it still retains. Occasionally since, unmindful of the submission due to the government which educates them, the students have, as in 1816 and 1830, demanded to put themselves in opposition to the measures: the acts of insubordination which took place in 1845 appear to have originated merely in a dislike which, for some reason, the students entertained to a person who had been the examiner at the examinations. These acts were of violente that the king, Louis-Philippe, entirely suppressed the institution. It has, however, again been revived, and, except a few of the most culpable, the same students have been readmitted.

The object of the Polytechnic School is still the same as its formation; and the young men are educated for the following branches of the public service: viz., the artillery of the line; gendarmerie, military and le genie maritime; the marine royal and the corps des ingénieurs hydrographes; the ponts et chaussées and the mines; the corps royal de d'etat-major; the poudres et salpêtres, and the administration of the tabacs.

The number of students is now reduced to 200, and the duration of the course of instruction is two years. Each student subscribes annually 1000 francs (411. 13s. 4d.), and the expense of his clothing is, in addition, about half that sum. The commander-in-chief of the French army is the head of the institution, and all the students are subject to military law. A candidate for admission must be a native of France, or a naturalized subject of the kingdom, and he must be between the age of twenty and thirty years of age; he, however, admitted till the age of twenty-five; but they cannot receive leave of absence, to prepare themselves for the examination, till they have been two years with their regiment.

The government does not engage itself to receive in its employ all the young men who have been educated at the school; but such as pass their final examination are allowed, according to the degree of merit which is awarded to them by the jury appointed to decide respecting their qualifications, to enter one of the branches of the public service as far as the vacancies will permit. In the gift of the Ministre de la Marine there are four scholarships, in that of the Ministre de l'Intérieur eight, and in that of the Ministre de la Guerre twelve; and these are for the benefit of youths whose parents or guardians are unable to pay the subscription. They are entitled 'places gratuities,' and each is equivalent to two thousand 'planches demi-gratuites' which the minister may grant to persons who are capable of paying half the amount of the subscription. The programme of the subjects, a knowledge of which is required preparatory to admission, is very nearly the same as that which has been given above. The students rise at 5 A.M., and breakfast at 7 A.M.; their hours of study and recreation for each day are regulated, and they dine at 2 P.M. To be sun at 8, and at 9 P.M. The lights are extinguished at 11. The 'Jour de l'Ecole Royale Polytechnique' continues to be published by the 'Conseil d'Instruction,' and it contains many valuable essays on subjects relating to the highest branches of scientific learning, and a special section contributed by La Grange, Monge, Le Place, Poisson, Prony, and other celebrated men; and those of more recent date are written by the ablest mathematicians of France, several of whom have been pupils of the institution.

**PO'MELE.** A species or sub-order of the natural order of Rosaceae. [Rosaee, P. C.] The following is a synopsis of the genera belonging to this section of plants:

1. *Cydonia* (Cydonia oblonga, 5-cleft; petals orbicular; ovary 2-5-celled; styles 2-5, glabrous; the fruit fleshy, ovate, containing a bony pome. [Cy-

2. *Cydonia reticulata* (from *maje*, a needle, and *Aeric*, a scale). The limb of the calyx funel-shaped, deciduous; the ovary 2-celled, 2-styled; the fruit with a thickened closed disk, and a papery pustule containing 5 gibbous seeds. [Cya-

3. *Crataegus* (gier, ground, and *maje*, an apple). Calyx truncate, with 5 little teeth; the petals small, cross; the stamens 10-15; the ovary 1-celled; the style long; ovaries 2, erect.

4. *Pyrus* (from *pyrus*, shining). Calyx 5-cleft; petals reflexed; ovary villous, 2-celled; styles 2, glabrous; fruit 2-celled inclosed in the fleshy calyx.

5. *Eriobotrya* (from *Eri*, wool, and *botrya*, grape). Calyx woolly, 5-toothed; petals bearded; styles 5, plisse, inclosed; fruit closed, 5-3-celled.

6. *Cotoneaster*. Flowers polygamous; calyx turbinate, bluntly 5-cleft; petals short; stamens of nearly equal length of the calyx- cine teeth; styles glabrous, shorter than the stamens; 2-3 carpels, pterial, inclosed in the calyx with 2 ovules. [Cot-

7. *Sorbus*. Calyx 5-cleft; petals lanceolate; stamens shorter than the calyx; ovary of 10 cells or 5 bipartite ones with a solitary ovule in each partition; styles 5, joined at the base; fruit 3-5-celled; seeds 3-5; the endocarp car-tilaginous, semi-transparent.

8. *Malus*. Calyx 5-cleft; segments foliaceous; petals nearly orbicular; disk large, filled with honey; styles 2-5, glabrous; fruit turbinate, open at the apex, 5-celled; endocarp bearded, and like the petals.

9. *Osculeia* (from *serio*, a bone, and *maje*, an apple). Calyx 5-cleft; petals oblong; styles exerted, the same length as the stamens, bearded below; ovary 5-celled; cells 1-seeded; fruit round, woolly, and red, inclosed.

10. *Pyrus*. Calyx urceolate, 5-lobe; petals roundish; styles usually 5, rarely 2 or 3; fruit closed, 5-celled; cells cartilaginous; seeds 2 in each cell. [Pyrus, P. C.]

11. *Alum.* Calyx 5-cleft; petals orbicular; styles 5; fruit closed, 5-celled; cells cartilaginous, many-seeded; seeds covered with pulp.

The species of the genus Raphilepria are known by the name of Indian Hawthorns. They are natives of various parts of Hindustan and China. There are six species of this genus, four of which have been cultivated in this country, and introduced as species of Crataegus or Measopus. These are—

1. *R. indica*. Tree of Military Order. It is a native of China; *R. indica*, a native of Cochin-China; and *R. salicifolia*, a native of China. All the species are trees in their native climates, with evergreen crenated coriaceous leaves, and flowers in terminal corymbose panicles, followed by small fruit. They require the same treatment as the species of Crataegus, and are eminently ornamental.

2. *P. serrulata* and oblong acutum serrulata, and is a native of Japan and China. It has been long cultivated in Great Britain as a standard in the open air, in warm situations. Where there is too cold a grow it is standard, it may be placed against a wall. *'Fit associates for it against a wall are Pho-

3. *Eriobotrya japonica*. (London.) That species is the only one that could be called a standard, it has been cultivated in this country. There are four or five other species described, natives of Asia, which might probably become with success.

4. *Eriobotrya* are less hardy than those of the
last genus. They are small trees with tomentose branches, broad simply serrated leaves, which are woolly beneath, with silky compound terminal racemes of flowers, and subulate deciduous bracts. *E. japonica* is the common Loquat. It has broad elliptic serrate rather wrinkled leaves, tapering at the base and acuminate at the apex, and the fruit is greenish yellow, globular, with a single seed, enclosed in a fleshy scarlet aril, and surrounded by three leaf-like persistent bases that usually remain on the tree. The plant is a small tree attaining a height of from 10 to 20 feet, and is a native of China and Japan. The fruit is of a mellow size, pear-shaped, yellow, downy, and disposed in large pendulous branched clusters. The seeds are indehiscent, and are set on a thin stalk. In the months of July, August, and September, and kept in a very warm house during the rest of the year. There are four other species of *Loquat* described, but none have been introduced into cultivation in this country.

**Amelanchier** is another genus separated by Lindley from the old genus *Mirabilis*. The species are small trees, natives of Europe and North America, with simple serrated deciduous leaves, white racemose flowers, and linear-lanceolate deciduous bracts. They are cultivated in British gardens on account of their early white showy flowers, their fruit, which ripens in June, and the deep yellow red which their vegetation attains in autumn. *A. vulgaris*, the common Amelanchier, has roundish-oval glabrous leaves, downy beneath, glabrous afterwards; the flowers are white, and appear in May; they are found in rocks in many parts of the continent of Europe. It has been in cultivation in England since the year 1596. *A. betulaefolia*, the Grime-Pear, has oblong-elliptical crowned with a brown down. It has a smooth brown bark, and is a little fragrant when wounded.

The *Pyrus amygdaliformis* of Sir J. E. Smith has been made into the genus *Osbeckia* by Lindley. At present this is the only known species. It is a shrub, native of the Sandwich Islands, with pinnate leaves and a small fruit crowned by the style and calyx.

The species of *Cydonia* yield the fruit called the Quince. *Cydonia vulgaris*, or *Quince*, P.C. F. C. S. No. 141

---

POOR LAWS, SCOTLAND. The foundation of the Old Poor Law of Scotland was the act of parliament, 1579, c. 74, which in reality did away with a poor law. It was so called because it was by the English statute of the fourteenth of Elizabeth, passed a few years earlier, as to have been considered a mere adaptation from it. The Scottish act, however, fell short of the English in the one important particular of not providing for the care of the able-bodied. By this act, a settlement was acquired by birth, and once so established could not be changed unless by a seven years' industrial residence in another parish. By the act of 1672, c. 18, this period was shortened to three years. The method of administering the law, which arose partly out of the terms of the old acts, partly out of custom, and partly through the law-givers' mistaken idea that he was a party by the judgements of the court as follows: In the rural parishes, the 'kirk sessions,' or lowest ecclesiastical judicatures, consisting of the parish clergyman and certain elders, shared the management with the 'tithers,' or rated land proprietors; but it became customary for the latter to interest themselves solely in the voting and levying of the rate, leaving its distribution and the management of the poor to the former. In those munici in the towns, the duty of the assessment and management lay with the corporate authorities. The funds for the relief of the poor were of two kinds. The collections at church doors, along with certain fees and deconchyances being assessed on the properties of the inhabitants. The rates assessed on the parish, or a substitute voluntarily paid instead of an assessment, the other. Of the sums collected at the church doors only a half went to the regular relief of

receiver of an air-pump will, by the pressure of the atmosphere, be forced through the wood and fall from thence in a shower. Liquids also are from being fluid by being pressed into the pores of paper, and in the Florence experiment, for determining whether or not water is compressible, the fluid was by pressure forced through the pores of the paper, and dried in the air. The porosity of bodies is inferred from their elasticity and the sounds which are heard when the molecules are in a state of vibration: also, in transparent bodies the least dense may be more easily shocked into a state of oscillation, and made to vibrate than the denser, for it is inferred from the fact that the particles of light pass through them, or that the vibrations of an external fluid take place among the molecules. It may, therefore, be said that the porosity of bodies is inferred from the fact that they are open to a certain degree of volume by being exposed to cold, and by mechanical compression, since such contractions can only take place in consequence of the particles being forced closer together than they are in the unpressed states of the bodies.

When salt is dissolved in water, the particles of the former seem to introduce themselves between those of the latter, so that the volume of the mixture is less than the sum of the volumes of the separate substances; and the like may be said of the mixture of alcohol with water; in which cases the particles of one of the kinds of substance appear to enter and occupy those of the other which are less capable of being filled up by the space that is left unoccupied. The mutual distances of the particles of gaseous substances are very great; and though, in some cases, the volume of a mixture is equal to the sum of the volumes of the separate gases, yet, in others, it is less than this. The inaccuracy in this case seems to be from the fact that they suffer contractions of volume by being exposed to cold, and by mechanical compression, since such contractions can only take place in consequence of the particles being forced closer together than they are in the unpressed states of the bodies.

All material substances subject to attractive forces, it has been made a question whether the attractions which take place between the molecules of bodies, and which are insensible at all appreciable distances from them, are the same as that general attraction by which bodies are attracted through space; modified, however, by the figures and mutual distances of the molecules, by heat, electricity, and perhaps by powers which are at present unknown to us: but, in order that this hypothesis may be admissible, the dimensions of the molecules of bodies should be extremely small compared with those of the spaces among them; and the densities of the molecules immensely greater than the densities of the bodies themselves. *La Place* estimates ("Système du Monde," ch. xviii. 4th ed.) that a molecule of a spherical form, whose diameter is one millionth part of a metre, ought to have a density more than six million times as great as the mean density of a body of the same size. Their attraction is equal to that of terrestrial gravity; and he observes, that the attractive forces exercised by the molecules of bodies, which are probably only the excesses of the entire attractions of the atoms of which the molecules are composed, must be vastly greater than that of gravity, since the actions of the molecules of a body produce visible effects of the rays of light, which cannot be ascertained concretely by the eye.

**PORTER, SIR ROBERT KER, K.C.H.,** was born at Durham in 1780, but his early boyhood was passed in Edinburgh, whither his mother removed upon the death of her husband, who was an officer in the English army. He was the brother of Anna Maria Porter and Jane Porter. His strong natural disposition for the arts was first called into activity by the celebrated Flora Macdonald. Sir Robert, then a boy of only ten or twenty years of age, was spending the evening with his family in the house of that extraordinary lady, who, perceiving his fixed attention to a certain battle-piece, explained to him that it was one of the battles of 40; and she proceeded to describe the battle in all its details in such glowing terms that the boy's blood kindled, and from that moment he became a painter of battles. From this time he was incessantly sketching battles, and his mother was induced by his evidence of talent to take him to London, in order that he might have the opportunity of instruction in the Royal Academy. His mother took him, in about 1790, to West, the president of the Royal Academy, who is said to have been so pleased with the boy's skilful drawing, that he procured his admission into the academy, and predicted his certain success with confidence. Sir Robert's careful portraiture reminds that of a well-known artist so much as to be easily mistaken for one. In 1793 he had already evinced such extraordinary progress as to receive a commission to paint an altar-piece for Shrorditch church. In 1794 he presented an altar-piece of Christ allaying the Storm to the Roman Catholic chapel at Portsea; and in 1798, another of a storming in the Wilderness, to St. John's College, Cambridge. His most extraordinary productions, however, were his great battles. In the year 1800 he exhibited an immense picture of the Battle of Trafalgar, 20 feet long, in the Great Room at the Royal Academy, presenting the storming of Seringapatam. He is said to have been only six weeks in painting the picture, and yet the execution was in no part neglected. West, after he had seen it, went to some of the academicians to inquire of their impressions, and said, he had just looked what he must consider a wonder in the art: a work of such dimensions, finished throughout, in a brevity of time which any other man would demand even to prepare the ground on which it is painted. Porter, hardly then in his twentieth year, this picture was burnt in the fire which consumed a friend's warehouse where the painter deposited it before he left England to go to Russia; but the sketches exist, and were sold at the sale of Sir Robert's effects in 1843. Another great battle was the Siege of Acre, exhibited also in the Lyceum Room in 1801; he published at the same time a book entitled "The Siege of Acre," chiefly intended as a companion to the great historical picture painted by Robert Ker Porter, now exhibiting at the Lyceum, 1801; it contains spirited etchings of the picture. These were followed by the Battle of Alexandria, 1802, to which he presented to the City of London, and it is still in the possession of the corporation: it was hung up in the Guildhall a few years ago. He painted also pictures of the Battle of Albufera in 1805, and the Battle of the Cape of Good Hope in 1806. In 1804 he went to Russia, and was appointed historical painter to the emperor. While he was in St. Petersburg he gained the affections of the Princess Mary, the daughter of the Prince Theodore de Sherbatoff, of Russia, and the marriage was arranged; but some ministerial differences caused him to leave Russia; in the year 1811, however, the marriage took place, and the princess survived him. He painted at St. Petersburg, on the walls of the walls of the Admiralty, the planning the port of Cronstadt and St. Petersburg. After his return to England, about 1806, he published 'Travelling Sketches in Russia and Sweden.' In 1808 he accompanied Sir John Moore's expedition to the Peninsula, and attended the campaign throughout, up to the closing catastrophe of the battle of Corunna. On his return to England he published some anonymous letters from Spain and Portugal.

After his return from a second visit to Russia, after his marriage, he published, in 1813, 'An Account of the Russian Campaign,' and he was knighted by the Prince Regent in the same year. He executed many sketches of the campaign in Portugal, and in 1817-18-19-20 was in France, 1817 to 1820, occupied in his extensive travels in Asia, of which he published a detailed account in 1821-22—"Travels in Georgia, Persia, Armenia, Ancient Babylonia, &c., during the years 1817-18-19-20." He wrote also "Costumes, Antiquities, &c.," 2 vols. 4to. In this work are many excellent designs in outline from the fine characteristic ancient sculptures of Nakshi Rostam, Nakshi Rajah, Shiraz, and Persepolis. The artist's attention is called to the representations of the basi-litiavi of the steps at Persepolis will show how extremely inaccurate and insufficient are the previous engravings given by Le Brun, Niebuhr, and Chardin. Some of the figures of these sculptures, which in Le Brun's time (1704) were mere headless trunks, are represented by Niebuhr ("Reisebeschreibung," &c., ii. 180), half a century afterwards, with eyes and noses complete, but executed without the least skill whatever; the representations of Sir John Chardin are not much better.

In 1823 Sir Robert Ker Porter was created Knight Commander of the order of Hanover, by William IV.; he was appointed a few years before British consul at Madrid, where he resided at Caracas until 1841, and he painted while there three sacred pictures, which were his last principal works; he also made numerous sketches of scenery in the meanwhile. The first of these three pictures was Christ at the last Supper blessing the Cup, painted as an altar-piece for the chapel of the Protestant burying-ground, of which he had procured the establishment; but he removed it afterwards on account of the representations of the scenes of the Ten Commandments in the native language. The second was our Saviour blessing the Little Child; and the third and last was an Ecce Homo, of which he presented as portraits of General Bolivar. In 1841 he sold his last visit to St. Petersburg, and the cold winter appears to have been too...
match a his is he a concave bractlets the the a sometimes now 4-flowered. 3rd from tish swans, by tions to the tish which on opening the 25 of the carriage, perceived that his master was holding himself in, and that he moved to the door with much difficulty; but before he could descend the steps he fell down from the effects of an apoplexy which was caused by his having taken a little water, soon after which consciousness ceased, and he expired at eight o'clock this morning (May 4, 1842), in his sixty-second year. His effects were publicly sold in London, in March, 1843.

(Athenæum, 1842-48, and the Artist's Works.)

PORTFIRE is a composition consisting of saltpetre, sulphur, and mixed gunpowder, mixed together by being rubbed between the hands, and, after being passed through hair-skeins, moistened with spirits of wine: the mixture is then rammed or driven into a paper case of a cylindrical or conical form, and less than an inch in diameter. A piece of portfire sixteen inches long will burn from twelve to fifteen minutes.

It is sometimes used as a match for firing artillery, in which case the saltpetre, sulphur, and powder are in the proportion of 6, 2, and 1, respectively; but it is frequently employed for the purpose of lighting rapid-firing guns, when the equations of the like ingredients are 7, 2, and 8, respectively. For these last purposes the portfire is attached at the extremity of the train, or is inserted in the shaft bored in the rock or object to be blasted; and the fire thus applied to it by a match.

POTIDONOMYA [Poston, P. C.]
POSSESSION FRATIS. [Dacret, P. C.]
POST HORSES. [Postig, P. C.]
POTAMOGETON (from ἄποκτας, a river, and the termination ὑγων, which probably means 'produced'), a genus of plants belonging to the Endogenous class, and the natural order Potamaceae. It has a perfect flower, a 4-carpellate perianth, 4 sepaline anthems opposite to the divisions of the perianth, 4 ovaries, and 4 drupes or nuts. The species are water-plants.

P. natans is a British plant, with floating oval stalked leaves, the peddles plano-concave above, the nuts large, rounded on the back when fresh keeled; when dry the peddles are equal. There is a creeping rhiza at the bottom of the water. The roots are sometimes eaten in the wilds of Siberia by men, but in more temperate regions are fed on only by swans, who devour them with avidity.

P. crispus has a compressed stem, peddiluc oblong linear leaves, sessile and wavy, the nuts with long beaks, keeled on the lower and then dry the peddiles are equal. It is a native of Great Britain.

P. denus has its leaves all opposite, peddiluc, clasping, elliptical-lanceolate or lanceolate; the spikes shortly stalked, ultimately reduced; the spike is 4-flowered. For it is famed in ditches and ponds of water in England. Ducks feed on the seeds and leaves of both these species, but they serve a more important purpose in giving out oxygen, and rendering the water respirable for fish and other aquatic animals. There are twenty British species of Potamogoton, and Haller says that in the Swiss lakes P. serratum grows to the length of from 10 to 20 fathoms, forming extensive subaqueous forests. (Burnet's Outlines of Botany; Barbington's Manual of British Botany.)

POTAIOMYIA, a genus of Conchifera from the fresh-water strait of Beacon Hill, in the Isle of Wight. (Sowerby.)

POTATAVILLA (potatis, powerful, from the supposed medical qualities of some of the species), a genus of plants belonging to the natural order Rosaceae. It has a conceve calyx from 4 to 5-parted, with 4 or 5 bractelets; there are from 4 to 5 petals in the perianth, 5 stamens, a larger, round, or nearly terminal style. The fruit consists of numerous small nuts placed on a flattish dry receptacle; the seeds pendulous or ascending, the radicle superior, the flowers white or yellow, rarely red. It is divided into the following species:—it is found likewise in other parts of Europe. The stem is filiform, procumbent, and creeping; the leaves quinate and stalked; the leaflets obovate, serrated; the peddiles solitary; carpelline above 4, ovum; the fruit sessile; style short; the seeds very small.

POTATOMON + PLANTS. When plants are placed to grow in a small earthen vessel, like a garden-pot, their condition is very different from that to which they are naturally exposed. The roots have not liberty to extend themselves as they choose; nor can they go out of themselves or round the vessel in which they are confined; they are likewise exposed to great varieties of temperature and depend on an uncertain supply of moisture. It is therefore the business of all who undertake these experiments to secure the advance of their plants.
tages derived from the operation itself. These advantages consist mainly in the facility with which it enables the gardener to change the arrangement and position of his plants; it also, by cramping the roots, diminishes the tendency to form leaves, and increases the disposition to flower. It secures a constant and effective drainage from the roots, and renders it more easy to expose them to a favourable amount of bottom heat. For the raising and nourishment of young seedlings it is also an advantageous process. Exhaustion of the soil is one of the inconveniences which result from this system. In order to remedy it liquid manure should be applied; or the plants placed in pans-feeders, shallow earthen vessels containing a drainage, to which the roots are admitted through holes in the bottom of the pot. It is however to shifting more particularly that recourse should be had for renovating the soil; and this, if skilfully performed without injuring the plant, is most successful. It is not alone for the purpose of improving the soil that shifting is desirable; the roots if allowed to remain long in a confined space form a hard knotted mass, which is very unfavourable to the retention of moisture and the growth of the plant. All the earth therefore which clings to the roots should be carefully separated before the plant is placed in the fresh soil. The roots of a plant are always found to be in contact with the sides of the pot and this, being generally composed of a highly absorbent substance, is subject to great variations of temperature. The practice of planting greenhouse plants into the earth during the summer to obviate this is very undesirable, as when they are again taken up the roots are generally found to have taken advantage of the earth around them and to have fastened themselves in it. The best mode of counteracting the injurious effects of unequal temperatures is by the use of double pots, as recommended in "The Gardener's Magazine," iv. 576, the space between the two pots being filled with moss or some other substance retentive of moisture. The drainage of potted plants is of great importance, and in all cases a quantity of broken pieces of tiles and earthenware should be placed at the bottom of the pot to prevent the stagnation of water about the roots. To be managed perfectly a young plant should be placed in as small a pot as will grow in, and gradually and successively transferred to large pots as it advances. Dr. Lindley says: 'It is by paying constant attention to the shifting of the growing plant, by the employment of a very rich stimulating soil, and by a thorough knowledge of the kind of atmosphere which suits them best, that have been obtained those magnificent pelargoniums, cockscombs, and balansa, &c. that have so often and so justly excited the admiration of even the most experienced gardeners.' (Lindley's, "Theory of Horticulture.")

POUNDAGE. [Summit, P. C.]

POWER. We find that the article Power, P. C., does not answer the reference made from Powers, P. C. We briefly supply the defect here, and take the opportunity of describing some important suggestions which have been recently made as to the manner of conducting algebraical operations.

In fact, the manner in which the term power was introduced into arithmetic is seen. By definition, the fourth power of a, the product of the four a's, or \(a \times a \times a \times a\); and the same of other powers. But it is far more symmetrical to begin from unity; and to say that the fourth power of a is the result of four multiplications by a, unity being understood as the commencement. Thus the successive powers of \(x, x^2, x^3, \text{etc.} \) are \(1 \times x, 1 \times x \times x, 1 \times x \times x \times x, \text{etc.}\) denoted by \(x, x^2, x^3, \text{etc.}\). And the term root is the inverse of power, as follows:—If \(A\) be the nth power of \(B, B\) is the nth root of \(A\), denoted by \(\sqrt[n]{A}\). The peculiar algebraical character of the root is explained in Powers, P. C.

It is thus easily proved that when a and \(n\) are any two integers, \(a^m = n\); when \(m\) is greater than \(n\), \(a^m = a^n \times a^{m-n} \times a^{m-n} \times \cdots \times a^{m-n} \times a^n\). Also that, \(x^{m} \times x^{n} = x^{m+n}\), and that \(1/x^n = x^{-n}\), whenever \(m\) is divisible by \(n\) without remainder. These rules, if applied in defiance of the restrictions first mentioned, lead to such results which are unintelligible as far as the definitions have yet been stated. Their proper interpretations [Interpretation, P. C.] are as follows:—First, \(x^m\) must be allowed to stand for unity, whatever \(m\) may be; secondly, \(x^n\) must be understood to be \(1 \times x^n\); thirdly, \(x, m\) and \(n\) being positive integers, must stand for \(x^n\). When these new definitions are added, all the rules remain true, whether \(m\) and \(n\) be positive or negative, integral or fractional: and the system of algebraic powers is complete.

An algebraic expression is said to be arranged in powers of a letter, say \(x\), when the powers of that letter which enter are made to enter in ascending or descending order of algebraic magnitude. Thus \(a^2 + bx^3 - a^4 \times x^4\) is not at present arranged at all. To arrange in ascending or descending powers of \(x\), we must write it thus—

\[ bx - x + a^4 - a^2 - 1 \]

But even yet it is incomplete for many algebraical purposes, having no written indication of the fact that the ascent or descent is interrupted. Completely written in ascending powers, it should be

\[ bx^2 - a^4 - a^2 - a^3 - 1 \]

Written in this form, which may remind us of the use of a cipher in writing ordinary numbers, it is clear that we hardly need the expression less casually, and write it much more briefly, if we omit \(x\) and its powers altogether, and make some distinctive mark, analogous to the decimal point, between the parts which belong to the positive and negative powers. Thus the above might be written—

\[ bx^2 + a - 1 + a + 4 - 1 \]

Written in this form, which is analogous to the decimal notation of the positive and negative powers. Thus the above might be written—

\[ bx^2 - a^4 - a^2 - a^3 - 1 \]

Accordingly the answer is \(x^2 + 2x + 1\); and every stroke of the pen which the usual method contains, more than is in the preceding, is mere waste, and risk of error is bargained. Instead, let it be proposed to divide \(x^2 + 2x + 1\) into \(a^2 - 2a + 1\), or \(a + 1\). Now let us propose to divide \(x^2 + 2x + 1\) into \(a^2 - 2a + 1\), or \(a + 1\). The late Mr. Horner [Isleworth, etc., P. C. and P. C. S.] was the first who suggested the systematic rejection of the ascending or descending powers. An example of multiplication and division will sufficiently explain it. Suppose it to require to multiply \(2x^2 - 2x - 3\) and \(2x + 4\);—

\[ 2x + 4 + 1 - 5 \]

Accordingly the quotient is \(4x^2 - 11x + 27\) and the remainder is 772 + 33x - 45x^2. Mr. Horner himself did not live to publish this suggestion, which, simple as it is, seems never have been made before him. This paper is contained in "The Ladies' Diary" for 1839; having previously introduced the simplification into the 11th edition of Hutton's Course. Since that time a paper on "Algebraical Transformation," sent by Mr. Horner to the Royal Society, but not printed in the "Philosophical Transactions," has been pub-
POW

POZ

listed in the first and second volume of the *Mathematician*. Details and examples are given in Mr. Davies' *Solutions of Questions contained in Hutton's Course*, 1840, and in the 12th edition of that course, 1841.

But the greatest improvement in the operation of division, and one which contains the principle of a class of improvements, is one which Horner called the *synthetic method*, which amounts to deferring the actual steps of subtraction until they are wanted. If we were to proceed one step farther with the preceding division, -44 in the quotient would be followed by +77. This +77, if we look at all its components from the beginning, arises from +0 -11 +0 +68. In like manner -44 arises from +4 +4 +4 -0. Now arrange the process as follows:

\[
\begin{align*}
14 & + 3 & + 2 & + 0 & + 0 & -11 & -1 \\
-2 & + 8 & + 0 & + 4 & + 11 & + 24 & + 44 \\
+0 & + 22 & + 1 & + 0 & + 0 & + 0 & -4 \\
+1 & -4 & -4 & -8 & -8
\end{align*}
\]

4 -11 +24 -64 +77 +13 -45

Write the coefficients of the dividend horizontally, \(a, b, c, \ldots\), and of the divisor vertically \(p, q, r, \ldots\), taking care to change the sign of every term of the divisor except the first.

\[
\begin{align*}
\frac{a}{p} & + \frac{b}{q} & + \frac{c}{r} & + \ldots \\
\frac{q}{w} & + \frac{r}{v} & + \frac{s}{u} & + \ldots \\
\frac{t}{y} & + \frac{u}{x} & + \frac{v}{w} & + \ldots \\
\frac{w}{z} & + \frac{x}{u} & + \frac{y}{v} & + \ldots \\
\frac{z}{y} & + \frac{y}{x} & + \frac{x}{u} & + \ldots
\end{align*}
\]

Divide \(a\) by \(p\), giving \(w\), and then write \(w, v, u, \ldots\) and \(f\) in the successive columns which follow that of \(u\). Make up \(b+p-wq,\) the second column, and divide by \(q\), giving \(v\); write \(w, v, \ldots\) in the successive columns which follow that of \(v\). Make up \(c+q-vr\) and divide by \(r\), giving \(w\); write \(v, w, \ldots\) in the columns which follow that of \(w\), and so on.

Then \(w+v+r+\ldots,\) will give the coefficients of the quotient, and \(u+v+r+\ldots,\) made from the columns which have not been used to find quotient terms, will give the coefficients of the remainder. For example, we want to find some terms of the quotient of \(x^3 + 1\) divided by \(x^2 - 3x - 2:

\[
\begin{align*}
\frac{1}{1} & + 0 & + 0 & + 1 \\
-1 & -1 & + 0 & + 0 & + 0 \\
+0 & + 3 & + 1 & + 2 & + 0 \\
+0 & + 1 & + 0 & -20 & + 0 \\
1 & + 4 & + 7 & + 20 & + 41 & + 60 & + 9
\end{align*}
\]

Hence the quotient is \(x^2 + 4x + 11\), remainder \(-41 + 40x + 2x^2 = 40x^2 + 4x - 41\).

When the first coefficient is anything but unity, fractions are introduced into the quotient. To avoid this, proceed as follows: Let \(a\) be the coefficient of the first term of the divisor, multiply the successive coefficients of the dividend by \(1, a, a^2, \ldots\), turn the first coefficient of the divisor into 1, and multiply the second, third, fourth, \(\ldots\), by \(1, a, a^2, \ldots\). Proceed as above with the coefficients thus altered, and suppose that in the last line the quotient terms become \(u+v+r+\ldots,\) and those \(w, v, \ldots\) for the remainder \(u+v+r+\ldots\).

To find the true quotient terms write

\[
\begin{align*}
\frac{a}{w} & + \frac{a}{v} & + \frac{a}{r} & + \ldots \\
\frac{w}{z} & + \frac{v}{x} & + \frac{r}{u} & + \ldots
\end{align*}
\]

and for the true remainder terms write

\[
\begin{align*}
\frac{w}{z} & + \frac{w}{x} & + \frac{w}{u} & + \ldots \\
\frac{w}{z} & + \frac{w}{x} & + \frac{w}{u} & + \ldots
\end{align*}
\]

where \(am\) is the last power used in the quotient terms, *repeated*, not the next on to it. Suppose for example, we are to divide \(x^4 + 2x^3 + 3x^2 + 5x + 6\) by \(x^2 + 3x - 2\). Here, since \(x^4\) descends and \(m\) seconds regularly, we throw out \(x\) and \(m\), and the abridged dividend and divisor become

\[
\begin{align*}
1 & + 1 & + 1 & + 2 & + 4 & + 4 \\
2 & + 4 & + 8 & + 1 & + 0 & + 0 \\
3 & + 0 & + 4 & + 1 & + 0 & + 0 \\
3 & + 0 & + 0 & + 4 & + 2 & + 0 \\
+3 & + 4 & + 0 & + 0 & + 0 & + 0
\end{align*}
\]

Hence the quotient is

\[
\begin{align*}
1 & + 1 & + 2 & + 36 & + 20 & + 24 & + 48 & + 864
\end{align*}
\]

and the remainder is

\[
\begin{align*}
20 & m^2 & + 24 m^2 & + 48 m^2 & + 864 m^2 & + 16 m^2 & + 32 m^2 & + 4 m^2 & + 182 m^2
\end{align*}
\]

One of the easiest modifications of this rule is the division of \(ax^m + bx^n + \ldots\), by \(x - p\) or \(x - p,\) as explained in *Fractions, Decomposition of, P. C. S.*

**POZZO DI BORGO** (sometimes BARGO), CARLO ANDREOLI, a distinguished diplomatist, was one of that considerable number of remarkable men produced by the island of Corse in the earlier part and middle of the last century. His family had ranked among the nobility of the island ever since the twelfth century; and he was born on the 8th of March, 1764, at Ajaccio, also the native place of Napoleon Bonaparte. The latter was the younger by five years, but they were in early life intimate friends. After having received a careful education in his own country, Pozzo di Borgo went to finish his studies at Pisa; whence he had not long returned when Corse, now under the dominion of France, was excited and shaken, like all the rest of that kingdom, by the outbreak of the Revolution of 1789. He there attached himself to General Paoli; and, under the patronage of that venerable head of the patriots, he was appointed, along with General Gentilii, to proceed to Paris with the thanks of Corse to the Constituent Assembly for having declared the island an integral portion of the French territory. This mission led to his being nominated a member of the Legislative Assembly, which commenced its sittings in October, 1791. While in Paris, staying in this position, he was able to have attracted considerable notice by the knowledge and talent he showed in the diplomatic committee. When the Legislative Assembly was dissolved, in September, 1792, he returned to Corse, and there joined Paoli in those efforts by which he accomplished the liberation of his country for a season from France, and the restoration of a native government under the protection of England. When the new constitution was established, in the summer of 1794, Pozzo, who had previously acted as one of the Secretaries of the General Consult at Corte, by which the constitution was drawn up, was appointed, according to his biographer M. Capéfigue, President of the Council of State, that is, we suppose, the Board of Council, nominated by the King of England to assist the Vicerey. When the English abandoned Corse in 1797, he came to this country with the Vice-Admiral Elliot, (afterwards Earl of Minto); and he remained here for about a year and a half. While in England Pozzo was considered as the principal adviser and agent of the French refugees; and it is from this period of his life that we must date the real rise of his name, if not the formal, commencement of his diplomatic career. In 1799 he proceeded to Vienna, where he attempted unsuccessfully to bring about a coalition between Austria and Russia.

He continued to reside at Vienna during the war, and was sent as a minister of embassy to the several Courts of Europe. After the battle of Austerlitz and the peace of Friedburg (December, 1805) he returned to Vienna, and thence proceeded to Petersburg. When Prussia rose against Napoleon in October of the year following, and was about to be joined by Russia, Pozzo received the military rank of colonel, and was to have accompanied the emperor as one of his suite, when the scheme of the confederates was struck to the ground and annihilated by the fatal battle of Jena (14th October, 1806). He now proceeded once more to Vienna, where he endeavoured, without success, to induce Austria again to take up arms. Meanwhile war had, at the instigation of France, been declared against Russia by the Porte (30th December, 1806) and in the beginning of the year 1807 Pozzo joined the English fleet which was sent, under Sir Thomas Duckworth, to force the passage of the Dardanelles. He was present in the battle fought between the Russian and Turkish fleets under the command of Tchernoff on the 7th of July, when the Turks were signsly defeated. But on the 7th of the same month Russia made peace with France by the treaty of Tilsit, one of the articles of which provided for an armistice between
Russia and the Forte, which was accordingly concluded on the 24th of August following. Pozzo, all whose feelings were vehemently anti-Gallienian, now obtained Alexander’s permission to travel; upon which he proceeded to Vienna, and he continued to reside there until the destruction of the fifth Anglo-Austrian coalition against France by the peace of Vienna (14th October, 1809).

He now betook himself to Constantinople, whence he proceeded on the 24th of December to St. Petersburg. There he remained till the expulsion of the French from Russia in the winter of 1812, when he was recalled by Alexander; and, passing through Sweden, he met the emperor, who, as a prince of the blood in the crown of Sweden, had already engaged to join the combination against France by the treaty of Petersburg (27th March, 1812); but he still hesitated to commit himself by any actual movement. Pozzo, who had had an interview with him on his way to Kaliut, was now sent therefore to urge him, at the same time that other negotiations were opened with Moreau, and with Murat and Eugene Beauharnais; and he at last succeeded in overcoming his scruples. After the Congress of Prague (July, 1813), Pozzo, now raised to the rank of major-general, was sent to Bernadotte at Berlin; and it is said to have been by his representations that the Swedish prince-imperial was prevailed on to take part in the battle of Leipzig (18th October, 1813). Meanwhile, immediately after the previous affair of Gross-berlin (23rd August), Pozzo had been despatched to Frankfort, to take part in the military conventions; it was decreed in the council that, on the beginning of January, 1814, he proceeded to London, charged with a request from the allied sovereigns that Lord Castlereagh might be sent over to join their deliberations. He soon arrived in London, and was received by the minister, with whom he proceeded to Ruden, where the allied sovereigns were now assembled. He continued in close attendance upon the Emperor Alexander at the Congress of Chaumont, where he strenuously opposed the recognition of the offers made by Bonaparte, and throughout the rest of the campaign of the first months of 1814, till they had the satisfaction of entering Paris together on the memorable 31st of March, 1814. Indeed, as the possession of France was now confirmed by the restoration of the Bourbons, he was now nominated Russian commissioner to the provisional government, and was soon after despatched to England to bring over Louis XVIII., with whom he returned to Paris on the 3rd of May. He remained in the French capital till the meeting of the Congress of Vienna in the beginning of November. At the conferences there he advised that the dethroned emperor should be sent out of Europe; and he is said to have produced some coldness towards him for a time on the part of Alexander, but by his representations he procured the project thus suggested to be adopted. The congress of Vienna, however, had continued its session during this time, and, having thus joined the allied army as Russian commissioner, he was present in that character at the battle of Waterloo, where he received a wound. He now returned to Paris, and, declining Talleyrand’s invitation to take office in the French ministry, resumed his former functions of Russian ambassador, and in that capacity he signed the Treaty of Paris of the 20th November. Soon after the Duke of Richelieu, now head of the ministry, conferred upon him the rank of a count and peer of France. He does not appear to have again left Paris till he was sent, after the Spanish campaign of the Duke of Wellington, to England to discuss the claims, from which, however, he soon returned to the French capital. The death of the Emperor Alexander and the accession of Nicholas (31st March, 1825) did not alter his position; and he received with equal cautiousness the news of the outbreak of the Revolution of 1830; but he at last revisited St. Petersburgh in 1834. Passing on his journey thither through Vienna and Berlin, he had the Order of the Red Eagle conferred upon him by the emperor of Germany, whom he had not seen since the breaking out of the War of the East in 1835 he was sent on a mission to London; after a stay of only a few months he returned to his former post at Paris; but he was soon back sent to England to treat with the king and government of Great Britain. According to M. Capefigue, he died at this appointment as both a mortification and a disgrace, and it affected him greatly: but M. de Nesselrode considered him with the promise that as soon as they should have turned the Duke of Wellington from his inclination to join with Austria (de se rapprocher de l’Autriche) in the Eastern question, and should have supported the Tories in an effective manner, then M. Pozzo would return to Paris to follow his tastes and accustomed pursuits. M. Capefigue, as is largely in all his writings in information of this sort, of which no other writer has had the luck to hear, and which we must state to be true, says that Count Pozzo, however, got back to Paris ere long; and all that there is further to be told of him is that he died in that capital on the 15th of February, 1842.

(Extracted, with the permission of M. Capefigue, from his Correspondance; and with the permission of the publishers of the Biographie Universelle, vol. 77 (Supplement), pp. 497-507, by M. Capefigue, which has also been published separately.)

PRELATE. (Busson, P. C.)

PRESCRIPTION has, by the law of Scotland, a much wider operation than either by the civil law or the law of England, supplying the place of the Statute of Limitations in the latter system. It not only protects individuals from adverse proceedings which other parties might have conducted if the lapse of time had not taken place, but it in some instances creates a positive title to property. The prescription of a right of property can be established to be of a period of thirty or forty years—a period probably borrowed from the Præscriptio quadraginta annorum of the Romans. Whatever adverse right is not cut off by the other special prescriptions of shorter periods must be extinguished by prescription in thirty years. It is said generally to preclude the right of exacting performance of any claim, as to which no judicial attempt has been made to exact performance for forty years from the time when it was due. Hence, where the cause of redress is non-existent, the prescription must be both positive and negative. The party holding the property must, by himself or those through whom he holds, have been forty years in unchallenged possession of the property on a fair face of the thing it may be said, has no right, and is not charged by law, to real property, the long prescription is not applicable. It is usually stated in the Scottish law-books that it is interrupted by the minority of any person who could challenge the opposing right; but it would be more correct to apply in this case the phraseology of the French lawyers, who say it suspends prescription, as the years of minority are merely not counted in making up the period of forty years, while, when there is a judicial interruption, a new period of forty years commences to run. When the prescription applies to a pecuniary obligation, payment of interest or an acknowledgment of the obligation will interrupt it. It may be observed that there is an act, by a sort of prescription, which bars all claims on such a debt. When there is in Scotland any judicial inquiry as to the antiquity of a custom, it is usual to limit the period of the inquiry to forty years, as sufficient to establish its having existed from time immemorial. The government of Edinburgh with the proprietors of land to irrigate fields with the contents of the city sewer—the system increasing until it became offensive to the neighbourhood—these proprietors produced evidence of their having continued the practice for forty years; and although it had during that time increased from an evil felt only by the individuals immediately concerned with the practice, to the extent of a public nuisance, those proprietors have, so far as the dispute has hitherto gone, been able to defend themselves on the ground of prescription.

The other two other prescriptions cut off particular descriptions of claims or methods of supporting them. By the vicennial or twenty years' prescription, holograph writings, not attested with the usual solemnities of Scottish writs, cease to be "bear faith in" the hands of the writer: the suretyship is limited to seven years. Bills of exchange and promissory notes cease to have force after six years; but the debts which they represent, if they do represent debts, may be recovered by other actions. Theunkenial prescription cuts off all right of action, after the lapse of five years, on bargains provable by witnesses. It also protects agricultural tenants from a demand for rent after they have been five years removed from the land to which the demand is directed: the quarter's or three years' prescription, is very important. It cuts off claims on account of goods or services, the three years running from the date of the last item of the account; and also
of Scotland. His employment was merely that of copying old records, and his salary was barely sufficient for his humble wants.

In 1811 Pringle and a friend published a poem called ‘The Institute of Edinburgh’. The poem seemed to have been written in a fit of inspiration, and not in single words, but rather in a continuous flow, as if inspired by a sudden burst of creativity. It was widely appreciated and earned them some praise but no profit. In 1816 he was a contributor to ‘Albyn’s Anthology’, and the author of a poem in the ‘Poetic Mirror’, called ‘The Autumnal Excursion’, which was praised by Scott, and was the origin of Pringle’s acquaintance with him. About the same time he was busy with the project of establishing a magazine as a rival to the ‘Scott Magazine’, and when his plan was fairly well advanced he resigned his post in the Register Office, which he could resume if his project was unsuccessful. Among his coeditors were Lockhart, Wilson, Clogborn, Dr. Brewer, and Hogg. Early in 1817 the ‘Edinburgh Monthly Magazine’ appeared, of which Pringle was the editor. His most important contribution to the first number was an article on the Gipsies, the chief materials for which were furnished by Scott, unasked for and gratuitously, and which Scott had himself intended to work up into an article for the ‘Quarterly Review’. About the same time Pringle became editor of the ‘Edinburgh Star’ newspaper. The magazine soon fell into the hands of other proprietors, and changed its title to that of ‘Blackwood’s Magazine’. Pringle was editor, at the same time that he became joint editor of ‘Constable’s Magazine’, but disputes between Pringle and Blackwood led in a short time to a separation. Before this unwelcome change, he had married. Soon after, he published ‘The Excursion, and other Poems’, with little or no profit. The editorship of ‘The Star’ newspaper was unprofitable, and he resigned it; and probably derived little comfort from it. Sometime in 1819, he was again on his former seat in the Register Office, performing the laborious drudgery of a copying clerk to the Record Commission.

Meet four brothers, all of whom were farmers, had become more or less prosperous, and he proposed that they should avail themselves of the government scheme of colonizing the unoccupied territory at the Cape of Good Hope. The farmers had previously expressed an interest in the scheme, and in January, 1829, he was once again in the Register Office, and Pringle undertook the management of his farm till his arrival.

The party of twenty-four persons, consisting of twelve men, six women, and six children, having set sail, arrived at the Cape of Good Hope in April, 1829. On the 31st of June they reached Roodeval, on the Great Fish River, and after a toilsome march of some days arrived at their place of settlement, in the upper part of the valley of the Bavina’s River, or Riviere of Lambos, one of the smaller tributaries of the Great Fish River.

The small colony, having surmounted the first difficulties, became tolerably prosperous, and Pringle’s brother having arrived at the Cape at the end of 1832, resigned his seat, and was appointed to the post of government. His employment at Cape Town, as had been his original intention. Scott, Sir John Macpherson, and others, had exerted their influence with the colonial secretary, and Pringle was offered and accepted the situation of librarian to the government library. The salary was only 75l. a year, but afforded a fair ground-work of income to a working literary man. He at first received pupils for private instruction, and then, in conjunction with the Rev. Mr. Fairburn, a Dutch clergyman of the town, made arrangements for the publication of a periodical in English and Dutch. Lord Charles Somerset, however, who was the governor, would not permit any journal to be published except the Government Gazette. Pringle was obliged to submit, and wait the arrival of commissioners, who had been sent out by the British government to examine into the condition of the colony. The commissioners, when they arrived, approved of his plan; but their powers did not extend beyond that of making a report to the home government.

Meanwhile, he had followed him from Scotland, organized a private academy on an extensive scale, which was prosperous beyond their expectations. While occupied with this new business, he was surprised to receive a letter from the governor authorizing him to commence his periodical, the plan of which, it seems, had met with the approbation of Lord Bathurst, who was then colonial secretary.
The 'South African Journal' forthwith appeared, one edition in English and one in Dutch. Soon afterwards, Mr. Greig, a printer, commenced the 'South African Commercial Advertiser,' a weekly newspaper, of which Pringle became editor, as well as of the 'Journal.' The two works were continued without interruption, and the press was ordered to proceed to the printing-office, and assume the office of censor of the press. Pringle states that everything likely to be personally offensive to the governor had been carefully expunged; that the printers employed had taken all arbitrary powers, and having no legal means of resistance, threw up his editorship. Greig discontinued the publication of the newspaper, announcing to his readers his intention of appealing to the British government. Greig's press was immediately ordered to be scaled up, and himself commanded by warrant to leave the colony within a month. The Fasal at the same time assumed the censorship of the Magazine also, stating that if he had been aware of certain paragraphs in the second number he would have expunged them or suppressed the numbers. Pringle disclaimed his right of censorship, and on the 9th May, 1824, announced the immediate continuance of the work in his own hands. The society to which the king in council was got up by the respectable inhabitants, and the governor became alarmed. He summoned Pringle to appear before himself and Sir John Truter, the chief justice. He at first attempted to explain away the whole subscrip-

tion, and, failing in that, tried to cajole him, and bring him over by flattery; Pringle, however, resolutely refused to re-

consider his conduct. Magistrate received a promise that the press should not be interfered with except by legal process.

To this the governor would not agree, and Pringle retired, and immediately resigned his appointment as librarian. The result was that the governor's resentment pursued him till, finding himself ruined in circumstances of life, he moved to London, and in June, 1826, arrived in London. He applied to the government for compensation for his losses, which he estimated at 1000L., but in vain. Meanwhile he was engaged as secretary to the Anti-Slavery Society, a situation which he held till slavery was abolished; he became the editor of 'Friendship's Offering,' wrote and published a 'Narrative of a Residence in South Africa,' and contributed to the chief periodical works of the day.

In June, 1834, Pringle wrote to his doctor, to say, that in taking supper a crumb of bread passed down the windpipe, and brought on a violent fit of coughing; that a little blood flowed, which however soon ceased; but in his declining he felt a sensation as if there had been some slight abrasion of the part. This slight abrasion seems to have produced con-
sumption, and his medical advisers informed him that removal to a warmer climate afforded the best hope of his life. He was preparing to return to the Cape, and had actu-

ally engaged a passage for himself, his wife, and her sister, when an attack of consumption, operating upon his weak state of body, occasioned his death, July 23rd, 1834.

The greater part of Pringle's works probably consist of fugitive pieces written during the time when he was secretary to the Anti-Slavery Society; but his reputation as an author depends mainly on his 'Narrative' and his 'Poems.' His 'Narrative' is very entertaining; somewhat diffuse perhaps, but simple, distinct, and effective, interspersed with passages of picturesque power and beauty, and characterized throughout by the appearance of truth. He published also an 'Account of English Settlers in Albany, South Africa,' 12mo. His poetry has great merit. It is distinguished by elegance rather than strength, but he has many forcible passages. The verisimilitude is sweet, the style simple and free from all superfluous epithets, and the descriptions are the result of his own observations. His 'Afrikaner Sketches,' which consist of personal exhibitions of the country, the character-

istic habits of African, and the modes of native life in South Africa, are alone sufficient to entitle him to mean rank as a poet.

(From the General Works of Thomas Pringle, with a Sketch of his Life, by Leitch Ritchie.)

PRINOS (πρίνος is the Greek name of the Holly, which the present genus much resembles), a genus of plants belonging to the family Rosaceae, has been described. The flowers, a permanent half 6-leaf calyx; a 6-parted pericarp, 6 subulate erect filaments, a short style with an obtuse stigma, and a berry with 6 stones. The species are shrubs with alternate deciduous or permanent leaves.

P. verticillatus has oval deciduous acuminate leaves, serrated, pubescent beneath; small white flowers in little imperfect axillary umbels, which are nearly sessile. The calyx is small, 6-cleft, and persistent; the ovary monopetalous, spreading, without a tube, the border divided into 6 oblong segments. The fruit is a bright scarlet, rounded, supported by the persistent calyx and crowned with the stigma, 6-celled, with seeds red. A well-marked plant, with its outer borders and its cases of gangrene. The berries are said to be tonic, and Bigelow asserts that they are emetic.

P. glaber, Glabrous Winter Berry, has rather pubescent branches, evergreen crenate lanceolate coriaceous smooth shining leaves, a little toothed at the apex; the pedicels are axillary, usually solitary, for the most part 3-flowered. It is native of North America from Canada to Florida. The berries are black, and are called in Jersey 'Madder Berries.' It is a low handsome shrub, and is said to be one of the plants the leaves of which are sometimes used instead of Paraguay Tea. The hard sense of this genus is well suited for shrubberies, and will thrive well in any soil, but they prefer peat. They are readily propagated by laying down the shoots or by seeds. The stave species will grow well in a mixture of loams and peat, and ripened cuttings will root in sand under a band-glass in modern greenhouses.

PRINTS AND DRAWINGS. [COPYRIGHT, P.C.] PRISMATIC TELESCOPE AND SEXTANT. Instruments bearing these names were invented by Professor Amici, at Modena, and the former is briefly described by Sir John Herschel in his Treatise on Light in the 'Encyclopaedia Metropolitana.' In its simplest form it consists of two pairs of triangular prisms of glass, each pair being such that an object seen through the two shall be free from colour.

In order to understand its construction, let ABC, DEF, in

the plane of the paper, be the principal sections of the prisms, and PQ be one side of a square object having its surfaces per-

pendicular to the paper, so that the sides while passing through the prisms and PQ perpendicularly to the paper may be parallel to the refracting edges of the prisms; also let the eye of the spec-

tator be situated at II; then the light proceeding from the surface of the square will, after reflection in the prisms, pro-

duce in the eye an image of a rectangular form, having the breadth in the direction of PQ greater than PQ, the length perpendicular to the paper being unaltered. If now the rays emergent from the second prism be made to pass through two others similar to ABC and DEF, but having the plane of their principal sections perpendicular to that of the former prisms, the visible image of the square on PQ will have the length perpendicular to the paper increased as much as PQ was before increased while PQ retains the magnitude which it had acquired. Thus, after refraction through four such prisms, the image of the object is equally magnified in every direction, and is quite free from colour: and it is easy to per-

ceive that by suffering the rays of light to pass through other systems of prisms, similarly formed and disposed, any required degree of magnification may be had.

Sir John Herschel conceives that a telescope of this nature might be used with advantage for viewing bright objects, as the sun, since it would require no darkening glasses, and would be exempt from the inconvenience introduced by the use of telescopes of the usual construction when applied to this particular purpose.

An optical instrument, which is also called a prismatic telescope, is produced by the prisms PQ, PQ, the first two of which have the same length perpendicular to the paper, and its focus two prisms of a doubly refracting medium; thus producing two images of an object, which being, by moving...
The prisms, made to approach to or recede from one another, permit the instrument to be used as a micrometer. It was invented or improved by M. Bouchon, and is sometimes employed for the purpose of ascertaining the magnitudes of terrestrial objects, or their distances from an observer. It has also been used in measuring small angular distances in the heavens.

The two prisms may be of Iceland spar, or rock crystal, and may be placed in the form of a wedge whose principal section is a right angled triangle, as ABC or A'B'C', and the two are applied in contact with each other as in the figure. The prism on ABC is cut so that, AB being the axis of the natural crystal, the face passing through AC perpendicularly to the paper may be perpendicular to that axis; and the prism on A'B'C' so that the edge passing through B perpendicularly to the paper may be the axis.

Now, if rays of light fall perpendicularly on the surface which passes through AC perpendicularly to the paper, those which, as abc, suffer the ordinary refraction, will preserve their direction on passing through the double prism and also on emerging from thence at the surface passing through A'B', the same direction as if they had at their incidence on the opposite face; while the rays which, as c'd', suffer the extraordinary refraction, will, on arriving at the surface passing through BC, be turned from the original direction and take some other as ef to pass through the prism. According as the prism is of the kind called attractive or that which is called repulsive (suppose the former); then, on emerging from the surface standing on A'B', the rays will proceed in the same direction as fe, as if they came from points corresponding to k in the rays of produced, and will cross the ordinary rays in points corresponding to z. An eye placed near o so as to receive the rays of both kinds will perceive two images of the object from whence they proceeded before they fell on the prism. The constant angle at which the rays are inclined to another is measured by ach, k being in the direction of ef produced; and when the prism is of Iceland spar the angle ach may exceed 43 degrees; when of rock crystal it may amount to 10 degrees.

Let the double prism be placed between the object-glass O of a telescope and its focus, the face standing on AC being towards the former and perpendicular to the optical axis; and for simplicity, let the object be a straight line XY in a vertical plane having one extremity X in the axis OE; then x and y being the focus of pencils diverging from X and Y, after being refracted through the object-glass O, the line xy may represent the image of XY formed as usual by the ordinary rays in the pencil of light, and x'y', in a vertical line passing through xy, the image produced by the extraordinary rays; the angle x′z′x or y'y′ being that which was denoted by ach above. Therefore, if the angular deviation of the images formed by the two kinds of rays is small enough to permit the rays to enter the eye near E, after passing through the eye-glasses of the telescope (the angular deviation not being altered by the refractions in those eye-glasses) corresponding to the images of the two rays an angle will be subtended some angle at the eye. If the points k and k' in the prism are at the foci x and y of the object-glass, the two images of XY will evidently coincide; but, on moving the prism O the images will separate progressively from one another, the angular deviations being proportional to the distance of k from x.

Now, on the exterior of the telescope in a direction parallel to its axis, there may be formed a scale which, by means of an index moveable with the prisms, will serve to measure any subtended angles; thus:—The angle subtended at the naked eye of the observer by any object as XY, which may represent a straight line or the diameter of a circular disk, being less than the constant angle x′z′x, there will be found a certain position of the prisms at which one extremity Y of the line or diameter seen by the ordinarily refracted rays will pass through a point O, and the other extremity X through a point O', and an index placed at O will serve to measure the line or diameter seen by the extraordinarily refracted rays.

Then, the angle which the same object subtends at the eye, in that position being determined trigonometrically or otherwise, the point at which the index stands should be numbered so as to express that angle. The like operation being performed for an object subtending a different angle at the eye, if the interval between the points at which the index stands be divided by the number of equal parts by which the difference between those angles, and the divisions be continued in opposite directions, there will be constituted the required scale, by which the angle subtended when the images of any other line or disk are placed in contact, by moving the prisms, may be measured.

The prismatic sextant, invented by Professor Amici, is described in Zach's 'Correspondance Astronomique,' tom. vi. p. 584. It has no mirror, but, nearly at the place where the index-mirror is situated on a common sextant, there are two triangular prisms of glass whose parallel edges are perpendicular to the face of the instrument. One of these is fixed, and the other turns on one of its edges by the motion of the index-bar, the broadest faces being parallel to each other, and nearly in contact when the index is at the zero of the arc: the telescope also turns on a pivot near the prisms. The rays of light passing through the exterior faces of the prisms will, after two refractions and one reflexion, and after passing through the telescope, enter the eye of the observer, so that, by moving the index-bar, the images of the objects from whence the rays proceed may be made to appear in an interval with each other; when the angle subtended between the objects will be rather greater than twice that which is described by the movement of the index. If the prisms are of common glass, and the broader faces of the prisms make with each other an angle of 90 degrees, the angle between the objects will be about 204 degrees.

Then, the points of this sextant are that double altitudes of the sun, when on the meridian, may be observed by it, even at the equator, and that at sea the anterior and posterior horizon may be brought in contact, and thus the amount of the horizontal refraction may be determined. It may be added that very little light is lost by reflexion, and that there is no parallax for near objects.

PRISTACANTHUS, a genus of fossil placoid fishes, from the beds of Stonesfield. (Agassiz.)

PRISTIS. Three species of this genus of fishes are mentioned as fossil in the tertiary strata of England. (Morris's Catalogue.)

PRIVY SEAL. [Signet, Seal, P. C.] The Lord Keeper of the Privy Seal is a member of the Cabinet, and has a salary of £2000 per annum. By an Act of 2 William IV. c. 4 the Commissioners of the Treasury may abolish any of the offices of Clerks of the Signet and Privy Seal when they become vacant, and direct the duties to be performed by the remaining clerks.

PRIZE MONEY. [Prize-Money, P. C.] Apprenticeships and sales of prize and capture are made by agents appointed by the commanders and other commissioned officers. A certified list of the persons entitled to the capture is transmitted to Chelsea Hospital by the commanding officer. There is a penalty of 500l. for altering names. At the end of three months from the receipt of prize-money, the treasurer of Chelsea Hospital is bound to notify the 'Lord Keeper of the Privy Seal' and in two London morning papers that distribution will be made at the end of one month. In this notification the share of an individual in each class must be declared. Shares of the prize money of a non-military vessel, united in one 12th of the prize-money, paid to a master or soldier, will be paid only upon personal application, or to his wife, or child, father or mother, brother or sister, or to the agent of his regiment, or to any other regimental agent. A warrant of appointment, signed by the clergyman and one of the churchwardens or overseers. Personating or falsely assuming the name and character of a person entitled to prize-money with fraudulent intent is punished by transport for life, or to serve within theIncarceration, signed by the clergyman and one of the churchwardens or overseers. Personating or falsely assuming the name and character of a person entitled to prize-money with fraudulent intent is punished by transport for life, or to serve within the

The Prize Council may refer to the High Court of Admiralty matters concerning booty of war (property captured by land forces). The Prize Council may refer to the High Court of Admiralty matters concerning booty of war (property captured by land forces).
PROBATE AND LEGACY DUTIES. These duties yield a sum exceeding two millions a year. The legacy duty is charged on legacies of the value of 20l. and upwards out of persons, marriages, and settlements, also on the death duties of any uncle or aunt or their descendants, 6d. per cent.; to a great uncle or great aunt or their descendants, 8d. per cent.; to any other relation or any stranger in blood, 10d. per cent. The present duty is expressed in silver, as it is in the Act of 1825. For sums above 20l. and not exceeding 100l. the duty is 10s.; if there is a will; and if there is no will the duty of 10s. is chargeable on sums of 20l. and not exceeding 50l. The duties continue to increase according to a certain scale up to 1,000,000.

The following tables show the operation of the legacy and probate duties for nearly half a century; and in Porter's 'Progress of the Nation,' vol. iii. pp. 125-133, will be found some useful and interesting considerations on these duties as indications of the progress of national wealth:—

PRO/CULUS, a distinguished Roman jurist, the successor of Nerva the father. He belonged to the school of Laboe, and was a follower of that school's defendant named Proculian from him. [Lafr. Bntics., P. C. S.] It is generally stated that his name was Sempronius Proculus, but Pomponius (Dig. 1, tit. 2, s. 2, § 47) calls him simply Proculus. The passage of the Digest (31, s. 47) which is cited to prove that his name was Sempronius does not prove that it was. In this passage Sempronius Proculus sends greeting to his grandson, and asks him his opinion about a legacy. ' Proculus respondent,' Proculus gave his opinion, and therefore the grandson and Proculus are the same person; and as Zimmern remarks, Proculus the jurist might be the son of the daughter of Sempronius the grandfather, in which case his name would not be the true one. It has been conjectured that Proculus the jurist is the Licinianus Proculus whom Otho made Praefectus praetorio (Tacitus, Hist. i. 46, 82, 87, ii. 39, 40, 44, 50). Proclus is often cited in the Digest, and he is especially mentioned in a Descript of the Div. Fines as one of the eminent authorities (Dig. 37, tit. 14, s. 17). There are thirty-seven excerpta in the Digest from a work of Proclus, entitled Epitome, of which there were at least eleven books (Porson). If Proclus the jurist is the Licinianus, this is an only eight. One of the excerpts (Dig. 33, tit. 6, s. 16) has the title 'Proclus, libro iii. ex Posterioribus Lebonici,' which appears to be a separate work or commentary on the Posterioribus Lebonici. It is possible that Proclus is the same as Proculus Laboe (Dig. 33, tit. 7, s. 4), it is conjectured that the title of s. 16 (Dig. 33, tit. 6) should be 'Javolemus.'

PROCURUS, the original name given by Sorcery to a large group of fossil Brachiopods, most frequently found in the mountain-limestone series. Productus and, for part of the group, Leptura and synonymously.

PROMULGATION. Promulgation is from the Latin Promulgo, which is equivalent to Promulgo, and means 'to make public.' The modern sense of Promulgation of a Law is the making of it public by bringing it before the house of parliament in some way or other. Blackstone observes (Comm. i. 45), 'It may be notified by universal tradition and long practice, which supposes a previous publication, and is the case of the common law of England which being not to be notified, may be notified and read for that purpose, as is done with regard to resolutions, and such acts of parliament as are appointed to be publicly read in churches and other assemblies. It may hastily be notified by printing, printing, or the like, which is the general course taken with all our acts of parliament.' A law is a command from a political superior to a political inferior to do or not to do something, with a penalty attached to the violation of the command, and it is assumed by Blackstone that the command is made known in some way to all who are bound to obey it; or it is presumed that it is known to all. But as to 'a universal tradition and long usage,' it is a mistake to say that it supposes a previous publication. A law does not make itself make law: the usage must be pronounced to be law by some competent authority, and that is the only promulgation which it has. Promulgation by proclamation is very ineffectual: it only reaches those who hear it. Furthermore, a law cannot hear an act of parliament which is read in churches, for the churches would not hold one-fourth of the people if they all went to hear it read; and if they heard it read, very few would understand it. Proclaiming is at present the least efficient means of promulgating a new statute; but to all those who cannot read it is inefficaciously, and also to those who cannot understand it.

No remedy can be provided for these difficulties, and it is simply a positive rule of law that a new statute is binding on all persons who are under the authority of the power which makes the statute, from the moment that the statute is made and completed in due form. It is a foolish way of speaking to say that a person is presumed to know a law, when it may be very easy to show in many cases that he did not know it and could not know it. One kind of legal presumption consists in the assumption of a fact, which presumption may be disproved by evidence. But the presumption that a man knows the law is not an assumption which a man is permitted to disprove even if he can, and this presumption should be struck out of the list of presumptions and placed among positive rules of law.

If a man were allowed to urge ignorance of law as an excuse, it might be urged by a great majority of the parties to contract and in other cases too; and the trial of the fact of ignorance of law would give ample room for fraud. The positive rule that all the members of a state are bound by its laws, causes less evil than the admission of the excuse would.

Promulgation of a law among the Romans meant the placing of the bill (ruggia) in some public place where it could be read before it was voted upon in the Comitia. The Roman rule was that ignorance of law (ignorantia juris) was no excuse. (Paulus, Dig. 22, tit. 6, s. 3.)

PROPERTIES OF IRON, MEDICAL. Iron, in a purely metallic state, does not exert any appreciable influence over the human system. Nevertheless metallic iron is recommended as an antidote to poisoning by the salts of copper. Iron filings have been administered with a view to precipitate the copper in a solution of sulphuric acid, and to give the patient an easy mode of passing the passage of the bowels. A white of egg is a more prompt and generally more accessible antidote. The employment of iron filings to absorb fortior exhalations from the feet is less beneficial than that of recently prepared and freshly powdered charcoal put every morning into the shoes of those afflicted with this annoyance. Iron filings are sometimes prescribed, but before any marked effect can be produced by them, the metal must become an oxide or a salt; that is, here stated, and in the alimentary canal promotes this change, while alkalis retard it. This form has been adopted in the treatment of worms, chiefly from the notion that the worms would be annoyed and dislodged by the nitrogenous propensities of the iron. This is an erroneous view. (Antichymisty, P. C. T.) Tincture of sesquichloride of iron in infusion of quassia is extremely...
beneficial in all cases of worms, but its efficiency depends on its tonic and astringent properties.

A few only of the preparations and uses of iron can be given here. Sesquioxide of iron (rust, or the subcarbonate of sesquioxide of iron), has been given at times in doses so large as to be dangerous, and this dose is inadvisable.

The black oxide is not so liable to objection, as it is more soluble in the fluids of the alimentary canal.

Ammonio-chloride of iron possesses no advantage over the simple chloride; the tincture of which, called tincture of sesquioxide of iron, is extremely valuable, as an emmenagogue; it is likewise very beneficial in checking menstruation, proceeding from relaxation of the uterus. It checks hematuria from relaxation of the tissue of the kidneys. In frequently repeated small doses it relaxes spasmodic stricture of the urethra. But the sense of nausea and sinking which it causes, renders patients averse to its repetition. It acts as a potentiating agent when employed externally or to mucous membranes as an injection.

The dose can be given in small doses, in pills or otherwise. Its powers are often much heightened by combination with sulphate of quinia. In nervous debility and indigestion this form is valuable.

Feo ferri, which has less unpleasantness of taste than most of the other preparations of iron, and is therefore more acceptable to children, to whom also the viennin ferri is much preferred. Both these are nearly superseded by the citrate or ammonium citrate of iron, which is more acceptable.

The latter given in warm water or lemonade is relished by most children.

Indo of iron is a preparation of great value in strumous disorders.

The same may be said of the phosphate of iron, a preparation formerly in the London Pharmacopoeia, and now most unjustly excluded from it. In the phosphtic diastases of fecal subjects, with a tendency to rickets, it is invaluable.

The dose for children is a very few grains, cautiously increased.

The numerous preparations of iron recently introduced by chemists have not been sufficiently tried to permit them to be spoken of with certainty; but in many cases their utility is obvious. Of these the chief are citrate of iron, Potassio-citrate, Soda-citrate, Zinco-citrate, Magnesio-citrate, Ferro-citrate, and Citrate of quinine and iron; this last is of great service in tie doloureux.

Chalybeate waters often furnish the best medium for administering iron; especially when the iron is associated with a carbonic acid. When no free-carbonic acid is present, and in some instances even where it exists, the water of the springs should be received in and drunk out of 14 day.

This often prevents the spasm which is apt to occur when water is suddenly taken in the stomach.

Besides being reputed an antidote to the poisonous salts of copper, iron is asserted to prove an antidote to other violent poisons.

Hydrate of peroxide of iron, called also hydetared peroxide of iron, is considered a trustworthy antidote against arsenic, if administered promptly, while the arsenic is yet in the stomach, and not absorbed. Prussie acid may be decomposed or combined, so as to be rendered innocuous, by giving promptly, first, solution of carbonate of potass, followed by a very diluted solution of the proto-persulphate of iron; the other to be followed by a ferro-persulphate of potass in the stomach.

(See London 5th October, 1844, or 'Pharmaceutical Journ.' vol. iv. p. 373.)

Physiological Effects and Therapeutic Employment of Iron.

—Iron exists both in plants and many animals, as the manganiferous and birds, constituting an essential part of their fluids and solids: but, incorporated as it is thoroughly with them, it gives rise to none of those phenomena which it occasions when taken into the stomach. Upon the living tissues iron has tonic influence; and as its preparations greatly promote digestion, they excite the appetite and render more easy the elaboration of the aliment. The vitality of the digestive organs becomes thereby increased from the incorporation of these principles, and thereby furnish a greater quantity fit to be assimilated.

These beneficial effects are best seen when the medicine is given in small and long-continued doses, or in the greatly diluted state in which iron occurs in the mineral waters or chalybeate springs. On the other hand, chalybeate occasion at times, especially if in large doses, pain of the epigastrium, nausea, fulness and eructations, and great anxiety; consequently referring to the injurious action, which the preparations of iron make or exercise when they reach the stomach, upon its internal surface, and the nerves which are distributed upon it. The unpleasant effects may generally be counteracted by the substitution of tepid or cold, in place of hot, water, or by increasing the doses, gradually increased, or by diluting it with some vegetable substance of little activity.

Iron given in large doses, when it reaches the intestines, produces excitation, accompanied with a sense of heat in the lower belly; in others it occasions colics and frequent alvine defecations; while with a third set of persons none of these effects follow its administration.

During the use of iron the fauces invariably become blackened, which is caused by the tannin of our food acting upon the iron.
man edifice and colonnades within the court, and giving the exterior the aspect of a fortress—the propylaea of the Greeks were detached structures placed in advance of the sacred edifice itself, so as to mark very conspicuously the approach to it. Like the Athenian propylaea, those at Athens and the Acropolis have been intended in some degree to prefigure the temple itself, to which they conducted, their general appearance in front being almost identically the same as that of the frontispiece to the temple of Athens. The order of the propylaea repeats, by the by, and sameness of design do not say much for invention on the part of the architects, or for the capability of the style employed by them to impress distinct characteristic marks on each front, is a question, and the gateway conducting to it; unless we would rather suppose that the kind of prefiguration above hinted at was aimed at directly and studiously.

The general arrangement and character of a Greek propylæum may be described as similar to those of an amphistyle temple [Temple, P. C.], shorter however on its sides than the width in front, and without any cells, yet not entirely open to both fronts, but divided by an inner wall across it from side to side, into two portions, the outer one of which, answering to the pronaoς of a temple, was larger than the other; so that the whole may be more freely, if not more entirely, understood by the phrase the pronaoς and opisthodomus of an amphistyle temple, put together without any intervening cells, being separated only by the wall whose two sides, in which were as many open doorways as there were intercolumniations in the important façade.

Such was the disposition of the propylæa both of the Pantheon at Athens and of the temple of Eleusis, the only two examples of Greek temples at Athens which have been preserved, that is, so only by the drawings of it in the restituted antiquities of Athens: there were: indeed, as we learn from Pausanias (ii, 3) propylæum at Corinth, but of their architectural design we know nothing. The Athenian structure stands on the west side of the Acropolis, as may be seen by the cut in Pausanias, P. C. (vol. xvii. page 288, col. 2), which shows its relative position to the temple itself—an irregular one, the two buildings not being, by the by, in the same plane. This propylæum, which was begun by the architect Mnesicles in the 4th year of the 85th olympiad, and completed in five years, is of the Doric order, and hexastyle on both fronts; and the outer or western one was greatly extended by two flanking wings projecting forward at right angles, so as to enclose the platform on which an ascent of steps led up from below, and above which the porico and the two lesser colonnades forming the sides of the wings were raised upon three other steps. Thus the platform (78 feet from north to south, by 40 east and west) became an elevated open fore-court, presenting a principal portico in front crowned by a pediment, and two colon- nades on the sides, the first (of 19 feet 6 inches high, and the others 28 feet high) gave greater importance to the former; and a degree of scenic effect—combination, contrast, and variety was produced, very unusual in Greek architecture. The arrangement of the steps above is much more irregular, the lower flight of steps existing of which however there now exists no trace, they having been destroyed to make way for a Turkish battery to defend the approach to the Acropolis. In the second century of the Christian era that first ascent was flanked on each side by an equestrian statue (one of them conjectured by Chioslzer, from an inscription, to have been that of Agrippa, therefore it is probable that the other was that of Augustus), which, though later additions to the struc- ture, must have greatly enhanced the general appearance of the architectural ensemble.

Another of the remarkable circumstances which served to distinguish the Propylæum from a portico is that in the western or outer division there were two rows of inner columns placed not parallel with, but at right angles to the columns in front, and in a line with the two middle ones, thereby dividing the plan naturally into three distinct consid- erations, the centre one narrower than the other two, and forming an avenue to the principal doorway, which was the largest and longest of the five openings in the transept, and the two end ones the smallest. These inner columns, too, in the case of being of the same order as the exterior, were Ionic,—a very remarkable peculiarity, inasmuch as it evidences an intention to introduce the Doric order of architecture. The licence—so to call it was, however, fully justi- fied by the circumstances of the case, because columns of lesser diameter than the external ones were required, and also of such height as to reach the architrave solitio of the internal ceiling, which are in line with the top of the architrave of the external order.

The Eleusian propylæum resembled that of the Acropolis in nearly all particulars, except that it had no wings attached to it, like the Athenian. The space occupied by the Doric order had the style on both fronts, and had six Ionic columns within, similarly in two rows.

As modern structures partaking of the ancient Greek propylæum character the Capitoline Temple of Cæsarean-Roman date at Teicneæa at Milan [Cagnola, P. C. S.], and the London Terminus of the London and Birmingham Railway, in Euston-square, which, though only a distyle in antis is of both fronts, is a suggestive imitation of the Greek form of extraordinary magnitude. Both the modern examples, however, differ from the ancient ones in being entirely open, without any internal transverse wall; and the Italian has, moreover, a large open portico on each side, forming a passage through it in that direction.

PROTOCOCCUS. [Snow, Red, P. C.]

PROPTOAPERIUS, a genus of fossil plants, from the coal formation, includes Sigillaria punctata of Droniniati. (Prel.)

PROVIDENCE, O. I. D., is an island in the Caroline Sea, about 205 miles from the Mosquito Coast, and between 18° 19' and 18° 29' N. lat. and 81° 29' and 81° 28' W. long.

This island is nearly four miles and a quarter long, and two and a half in its breadth, that is, of an irregular oval shape.

The highest ground near the centre of the island rises to 1190 feet above the level of the sea, so that it can be seen from the shore.

From this point other hills, mostly wooded to their summits, rise to a height of a half a mile, and terminate in a bold coast. Separated from its northern end by a cut or channel of from forty to sixty yards wide, is the island of Santa Catalina, 1800 yards long by 1800 in its greatest breadth, forming the northern boundary of a harbour in Old Providence which affords secure anchorage in two to three and a half fathoms.

These islands are surrounded by an extensive bank of coral and coarse sand, which stretches to the northward a distance of ten miles and a half. The larger part of the island is unfit for cultivation, owing to its being extremely hilly. But the soil is very productive, and affords rich crops with very little cultivation. Cotton is the chief object of cultivation, and is annually exported to the amount of 30,000 pounds; the sugar-cane and coffee are also grown, but only in sufficient quantities for the consumption of the inhabitants.

Of various kinds, such as sapodillas, mangoes, oranges, tamarinds, plums, and limes are plentiful, and also coconuts. Yams and plantains are extensively grown, and afford the principal food. Seabirds and sea-fowl are prolific in number, and the shore is supplied with sea-fowl, which are paid for by the traders from Jamaica with calicoes, cloth, and a few articles of cutlery.

It is not well known when this island was discovered and taken possession of by the Spaniards. In 1664 it was taken from them by the famous buccaneer Manantel, who considered it well adapted to be the head-quarters of the lawless band of which he was the leader. After his death Morgan kept it, and fortified the island of Santa Catalina, but he left it when he was appointed deputy governor of Jamaica (1672).

After that time it appears only to have been visited occasionally, and remained uninhabited until 1795, when a few families from the New World settled there by the permis- sion of the Spaniards. From this time to 1817 it remained quite tranquil, when General Avery, a bold and energetic man, who had become a pirate, took possession of it and repaired the principal buildings of the bay, collected for his predatory excursions, was brought to this island, where a con- siderable trade was established. At his death (1822) the pirates dispersed, and the island returned to the dominion of the republic of I. D., and the population amounted to only 324 persons, about one-half of whom were slaves. They employ themselves principally in catching turtle, and they visit with their three vessels, from ten to fifteen ton burden, the bay of Old Providence, and speak the English language.

PRUNELLA, a genus of plants belonging to the natural order Labiate. It has two inferior stamens. The filaments bifid, one branch barren. The anthers all 2-celled. The ovary 3-celled, with 3 styles and 3 fruits; the fruit is a capsule, plump and inflated, the calyx is immediately closed and compressed, the upper lip flat, truncate, 3-toothed, the lower lip bifid.

*P. vulgaris*, Self-heal, is a native of Europe and Asia, very plentiful about dry sandy tracts in England. The leaves are stalked, ovate or oblong, toothed or deeply pinnatifid, the upper lip of the calyx with short truncate mucronate teeth, the lower lip with ovate-lanceolate mucronate teeth, the two lower lobes being set apart with a straight spine-like root at their apex. The flowers are purple, white, or nearly red. In the British specimens the leaves are nearly entire. This plant is considered astrigent, and was formerly used in our medicinal systems for astringence and inflammation of the fauces. Its repuse is now merely in name.

*P. grandiflora* has petiolar ovate leaves, quite entire or toothed, the lateral teeth of the upper lip of the corolla lanceolate, the corolla large, more than twice as long as the calyx. It is native throughout Europe in woods and shady places; the flowers are of a purple or violet colour, seldom white. All the species of *Prunella* are showy when in blossom, and are therefore worth cultivation in flower gardens and rock-work. They grow in any common garden soil, but thrive best in a damp moist situation. They are readily propagated by seed or division.

*P. montana* var. *hybrida* is a British species, New British Botany; Lindley, Vegetable Kingdom.)

PRUSSIC ACID—Medical Properties of. This acid, termed also hydrocyanic acid, has been described according to its behaviour in the human organism and its connection with medical jurisprudence, from the frequent use of it in cases of death, accidental or intentional, merit the most attentive consideration. But these are unsuited for present discussion. A few important rules and cautions can alone be furnished here.

Much variation in strength exists in the acid (that is, the dilute acid, for the enhydris is always of definite strength), over which, in general, the methods of preparation does a difference of strength exist in the acid as it is enjoined to be prepared by the Edinburgh and London colleges, but even in England two preparations are commonly met with, that enjoined by the London Pharmacopoeia, which contains 2 per cent. of real acid, and that which has been long known as Scheele’s, containing 4 per cent. The substitution of the one for the other in preparing a prescription might lead to serious if not fatal consequences. A still greater difference exists in the strength of the preparations met with in different countries of the Continent. No one in travelling should ever prescribe prussic acid, unless he has previously ascertained with what preparation will be employed in compounding the prescription.

As it undergoes decomposition by time, especially if exposed to the light, and is readily volatilised at a high temperature, it is kept in the dark in a cool place.

As it is specifically lighter than water, it rises to the surface in watery fluids. The fluid in which it is kept should be well shaken before pouring it out. When employed externally as a lotion, in which case it is used in larger doses than when meant for internal employment, great care should be observed to distinguish it, lest it should be accidentally taken internally. Even its external employment demands great care, for when the cuticle is abraded or cracked, it is readily absorbed, and may prove fatal. The cuticle, even when in a state of integrity, is not proof against the vapour of prussic acid. All bottles containing the acid should be kept well corked, as the vapour is the most potent form which can influence the human frame.

When first introduced into medical practice, high expectations were formed upon the utility of Prussic acid. Subsequent experience has moderated these expectations; but there is no doubt that it might be found useful in many instances where it is not employed, the dread of accidents deterring many medical practitioners.

Such is the case with those who know its properties should furnish a salutary caution to all persons against employing it on their own responsibility. The diseases in which it has been most regularly employed are, however, the production of the local inflammation, after the active stage is passed, or those of irritation. Among the former, hooping-cough is unquestionably benefited by it. But here great caution is necessary. Its premature employment, by checking the cough, induces inflammation, often of a very alarming kind. The dose should at first be very small, and most slowly increased. In some works, even emanating from medical men, large doses are recommended, and the caustic nature of the vapour, extracted from Conium than from this acid. Some affections of the stomach receive signal relief; others derive not the least benefit from it. The explanation of this appears to be that prevention of the aggravation of the disorder, as well as its seat, are in the stomach itself; while in the latter the pain is felt chiefly in the stomach, but the cause is in the spinal chord. Treatment directed to the spine will in general quickly and often permanently relieve it (Tuttle’s *Treatise on Neuralgic Diseases*). Cutaneous diseases are alleviated by lotions and ointments containing hydrocyanic acid. But the cautions above given must be carefully observed during their employment.

The most useful hints which can be here given relate to the treatment of poisoning by prussic acid. So soon as it is ascertained or suspected that any one has taken an over or poisonous dose, cold water should be dashed over the head and back. The vapour of ammonia (common smelling salts) or of chlorine should be applied to the nostrils; or very dilute liquor ammonium may be blown into the stomach. While these things are doing, other persons may prepare a weak solution of carbonate of potash (common pearlash will answer); and some sulphate of iron (coppers) is to be dissolved in a large quantity of water. Some of the solution of the carbonate of potash is to be poured over the patient followed immediately by some of the solution of coppers. This, if done promptly, will save the patient. Artificial respiration, if specifically resorted to, is useful, as is likewise bleeding from the arm. If possible, give a purge.

*PSALIODUS*, a genus of fossil fishes, from Sheppy, (Erseston.)

*PSAMMOMUS*, a genus of fossil shelled animals, from the mountain-lime stones of Bristol and Arungho (Arund.)

PSEUDOLIVYA, a genus of Gasteropoda, which includes one fossil species from the London clay. (Sowerby.)

PSI/DSIUM (from φυσ, the Greek name for a pomegranate), a genus of plants, common to Egypt. It has not been observed to cause symptoms of poisoning. The tube of the calyx is ellipsoid or obovate, usually contracted at the apex; the limb oval, undivided, but afterwards to 1- to 5-cleft. There are five petals and numerous free stamens inserted in a broad circle, almost through the whole undivided part of the limb; the style is filiform, the stigma capitulate: the ovules are numerous, horizontal, and fixed to the margin of the placenta; the berry is many-seeded, cordate by the tube of the calyx, and crowned by a large calyx. The seeds imbedded in the pulp in the mature fruit with a bovy testa. The species are trees or shrubs, natives of America within the tropics. The fruit is edible, and is known by the name of Malpighia. It has a fragrant and very sweet, very rapid taste, and is eaten both raw and when made into jelly.

P. pomifera, Apple-bearing or common Red Guava has tetragonal branches, oval or oblong lanceolate leaves, unscented beneath, from 3 to 8 peduncles or many-flowered. The fruit is globose, yellow, and somewhat astrigent, with an agreeable odour; the root and young leaves are astrigent, and are esteemed strengthening to the stomach. It is native of the West Indies, Mexico, and South America.

P. montana, has tetragonal branches, oval oblong leaves, acuminate and quite glabrous; the peduncles many-flowered, and the fruit roundish. It is native of Jamaica on the mountains. The fruit is small, acid, and smells strongly like bitter almonds, hence it is called *Ambrodon*. The wood is very hard and of a fine colour and grain. It works well, takes a fine polish, and is much esteemed for ornamental purposes. The species of *Guava* grow freely in a mixture of loam and peat. Cuttings will strike root in sand with a hand-glass over them. Some of the species bear fruit in the stoves of this country, but they are hardly worth the trouble of growing for this purpose.

(Don, Gardener’s Dictionary; Burnett, *Outlines of Botany*.)

PSYCHODRAGMARIA (from *γυναίκη*, woman, life, and *δρακός*, a dragon) the powerful medicinal properties of one of the species of a genus of plants belonging to the natural order Chironiaceae and the tribe Coffee. The limb of the calyx is 5-lobed, 3-toothed, or nearly 5-toothed, with a single tooth situated near the limb spreading or recurved, the throat bearded or gla- trous. There are 5 stamens, the anthers exserted or en- closed. The berry is drupaceous, crowned by the limb of the calyx, furnished with 10 blunt ribs in the dried state. The
species are small trees or shrubs, natives within the tropics; they are very numerous and intractable.

P. aquilinum has the leaves of the host in a broad, shallow, and branched root with a slender axis, and a thick friable back. It is an erect simple

hairy under-shrub, with oblong lanceolate leaves narrowed at the base, membranous or elate, rather plane beneath; stipules are small and very short. The pedicels are axillary and few, flowered somewhat racemose and white. It is the psevechana supplied by South America, and is the stunted psevechana of some authors. The root possesses similar effects on the brain, and is much used in the treatment of hysteria, and contains, according to M. Pelletier, 9 per cent, of cinantnine.

P. nozii is a native of Brazil, with compressed branched

furnished with two rows of hairs; the leaves are lanceolate, acuminate, and recurved. The stipules are short, bipartite, the flowers 2-4 in a fascicle, sessile, bracteate, terminal, and axillary. This species is accounted poisonous in Brazil; it is known by the name of Erva de rata, and is used for the destruction of rats and mice.

P. speciosa is employed in Brazil in the same diseases as

marapanda; and P. tintoria forms a fine red dye much valued in Peru. All the species of Psychotria are of most easy culture and propagation. They grow best in a mixture of peat, sand, and cuttings will strike root readily if planted in sand underneath a hand-glass. Some of them bear handsome foliage, but the flowers of all are insignificant.

(Don, Gardner’s Dictionary; Lindley, Flora Medic. Lindley, Vegetable Kingdom.)

PSYTHIRUS, a genus of Hypnumcicous insects of the family Anipida and division Sociales. It includes certain humble-bees structurally incapable of forming their own nests, and considered parasitic by St. Fargeau, the entomologist who established this genus.

PTARMICA, a genus of plants belonging to the natural order Astereace. It has a campanulate involucre with the scales brown and scoriaceous at the edge. The receptacle is flat or scarcely convex, broad, and paleaceous. The ligules from 5 to 20, flat, extended, much longer than the involucre. The achenia are bald, echiniform, the outer often somewhat winged at the edge.

PTEROCARPUS is a genus of plants widely creeping, root very difficult to extract, when the soil is moist. Upright stems about two feet high, angular, smooth, hollow, leafy, with small axillary rudiments of branches corymbose at the top. The leaves are sessile, linear, or slightly lanceolate acute, very minutely verrucous but with little teeth. Smooth on both sides and of a dark green. The flowers are millimetre, larger than most others of the same genus. The whole plant is pungent, and probably to one minute minutizes they become almost smothering; but this is thought to be owing to their little sharp marginal teeth; the root is aromatic. The heads of P. nova, atrata, and moschata are used in the Swiss Alps as a substitute for tea. Moschata is the basis of the aromatic liqueur called Esprit d’Eva.

(Lindley, Veget. Kingdom; Lindley, Flora Medic.)

PTERIDACANTHUS, a singular genus of fossil ganoine faunites from the old red-sandstone of Scotland and Orkney. (Agassiz.)

PTERID/MEA, a fossil genus of Cochlicers, allied to Avicula, and hitherto confined to the Palaeozoic, and chiefly found in the Devonian strata. (Goldfuss.)

PTERIS (from pteron, a wing), a genus of plants belonging to the natural order Filicae. The thecae arise from the points of veins placed on a nerve-like receptacle running along the edge of the leaf, forming an uninterrupted marginal sorus; the involucres are continuous with the edge of the leaf, scarios, and opening inwards.

P. aquilina, common Fern, or Braken, is the most abundant of the species. It has a long tapering creeping rhizome, externally black. The leaves are erect, from one to six feet high, repeatedly compound with horizontally spreading divisions, whose ribs are smooth; the primary leaves are nearly 1 inch, and pinnate; the secondary divisions oblong, obtuse. They are all a light bright green color, slightly brown at the edge, which is revolute and crisped, or wavy, shielding the dense linear masses of tawny scales below. The root is tough, rough, and very strong, but simply scarios. This tree is thought by Roxburgh to be the one yielding gum kino, a well known astrangent,—the juice hardening into a dark red and very brittle gum resin, which, on being powdered, changes to a light brown, very astrangent, the powder being somewhat strong, but simply astrangent. The red kino-tree however appears to be the next species.

P. arborescens is a tree 40 to 50 feet in height. It has un-equally pinnate leaves, 9 to 11 in each leaf, beginning 1 to 11 to 15 leaflets, alternate, distant, on short stalks, ovate, oblong, obtuse, or emarginate, warty at the edge; lanceolate stipules, solitary or clustered rhacemes, downy from the old wood below, the flowers in the leafy axils. The flowers are yellow, the foliage stipulate, compressed, membranous, velvety, serrate, and undulate, prickly on the centre. When the branches are wounded, a clear bright gum exudes from the中断, the root is known to the native as gummer, and is mentioned as such by Mr. Mango. It is

indicative of poor soil, but it is more probable that its

absence from cultivated ground is to be attributed to the effects of the heat and the alkaline character of the

soil. The geographical range of this species is very extensive; it is included in every European list, and is found also in Asia and Africa. It is used in many parts of England for keeping people in health, and in the islands of Ireland and Scotland, and persons who live in those countries gain considerable profit by collecting the leaves, and selling the ashes to soap and glass makers, on account of the large quantities of alkali contained in them. As a litter for rats and other vermin, and as a substitute for the

mass, this species is used for polishing leather. It is highly esteemed in South America for the manufacture of the root with luxury.

(Steele, British Ferns; Babington, Manual of British Botany; Lindley, Flora Medic.)

PTEROCARPA, from wop, a wing, and adma, a fruit, in reference to the pods being girdled with a broad wing. It has a 5-cleft calyx, a corolla with 5 petals, disposed into a papilionaceous form; 10 monadelphous or diadelphous stamens, an irregular indesiguin legumen, somewhat orbicular, surrounded by a wing, woody, and often rugose, in the middle 1-3-celled. The leaves are unequally pinnate. The racemes axillary, or forming terminal panicles. The species are unarmed trees or shrubs.

P. Draco, Dragon’s-blood, and Psychotria, is a tree nearly 30 feet high, with alternate shining leaves, about 5 on each side, and an odd one, rather obtuse, entire, veined, smooth, pale green below; the leaves nearly smooth. The wood of this tree is white and heavy, the bark thick and of a very grey colour. When first cut it presents no marks of redness, but in a little time red drops of juice begin to collect and exude from the wood. If left in the sun for about ten hours, it is rare and clear, and the wood is used in the middle 1-3-celled. The leaves are unequally pinnate. The racemes axillary, or forming terminal panicles. The species are unarmed trees or shrubs.

a very powerful remedy in obstinate chronic diarrhoea and dysenteries, and in all diseases arising from laxity of faeces. Externally it is applied to those parts to check hemorrhages from wounds and ulcers, and to diminish discharges.

_P. sanctius_ is a lofty tree having alternate stalked ternate leaves, petiolate alternate leaflets smooth above, hoary beneath. The flowers are yellow, simple, and oblong in perfect. The legume roundish, stalked, falcate upwards, compressed, smooth, keeled on the lower edge, the keel being prominent and unrolled. From this name is obtained the Red Sallee. The timber is chiefly consumed by dyers and colour manufacturers of the present day, but which is also used to colour several official preparations, such as compound tincture of lavender. Its colouring matter forms beautiful coloured powders for dying silk and other metallic substances.

_P. flavus_ is the yellow _sandal-tree_, and is used for dyeing yellow. Its bark is very bitter.

The species of this genus thrive best in a loamy soil, and young cuttings not deprived of their leaves root readily in sand under a hand-glass in heat.

(Don, _Gardener's Dictionary_; Lindley, _Flora Medica_; Burnett, _Outlines of Botany_.)

_PTEROPHYLLUM_, a genus of fossil Cycadea plants from the siltite of Yorkshire and beds of the same age in Scania. (Brockman.)

_Acanthoceras_, a genus of fossil corals from the Silurian strata of South, Westmorland, and Tyrone. (Lonsdale.)

_PTYXACanthus_, a genus of fossil placoid fishes from the old red and mountain limestone strata. (Agassiz.)

_P. temate_, a 320 genus of _Cephalopoda_ from the fault of Folkstone. (D'Orbigny.)

_PTYCHOUS_, a genus of fossil fishes from the Cre-taceous system of England. (Agassiz.)

_PTYCHOLEPSIS_, a genus of fossil ganoid fishes from the _flora_ of England, &c. (Agassiz.)

PUBLIC HEALTH. On the 14th May, 1838, the Poor Law Commissioners presented to Lord John Russell, then Secretary of State for Home Affairs, a Report by Dr. Arnot and Dr. Kay, and two Reports by Dr. Southwood Smith, relative to the prevalence of disease among the labouring classes in certain districts of the metropolis. The House of Lords having, on the 19th of August, 1839, presented an address to her Majesty requesting her to direct an inquiry to be made as to the extent of the causes of disease mentioned in those Reports, the Poor Law Commissioners received a letter from Lord John Russell, in which he stated that her Majesty required them to make such inquiry, not only as to the metropolis, but as to other parts of England and Wales, and to prepare a Report stating the result of such inquiry.

In 1840 the subject was investigated by a Committee of the House of Commons, the result of which was a Report 'On the Health of Large Towns and Populous Districts.' In July, 1842, the Report of the Poor Law Commissioners was laid before Parliament by the House of Commons. A 'Report on the Sanitary Condition of the Labouring Population of Great Britain,' by Edwin Chadwick, Esq. 'Local Reports on the Sanitary Condition of the Labouring Population of England and Wales,' prepared at the same time. Of these Local Reports there were twenty-six, some of which relate to certain counties and others to particular towns. At the same time these were presented 'Reports on the Sanitary Condition of the Labouring Population of Scotland.' In 1843 a 'Supplementary Report on the Results of a Special Inquiry into the Practice of Intemperance in Towns,' by Edwin Chadwick, Esq., was presented.

On the 9th of May, 1843, Commissioners were appointed by the Queen for the purpose of 'inquiring into the present state of the large towns and populous districts in England and Wales, with reference to the causes of disease among the inhabitants, and into the best means of promoting and securing the public health, under the operation of the laws and regulations for the preservation of health, and the usages at present prevailing with regard to the drainage of lands, the erection, drainage, and ventilation of buildings, and the supply of water, in such towns and districts, whether for purposes of health, or for the better protection of property from fire; and how for the public health and general good the sanitary condition of the population of the people of this realm, and the salubrity and safety of their dwellings, may be promoted by the amendment of such laws, regulations, and practices.'

The first Report of the Commissioners was presented to both Houses of Parliament at the end of June, 1844. The Report is accompanied by 437 folio pages of evidence on which the Report is founded, an Appendix of Special Reports on the sanitary condition of several districts, among the important of which are—Liverpool, by W. H. Duncan, M.D.; Ashton-under-Lyne, by John Ross Coulthart, Esq.; the City of York, by Thomas Laycock, M.D., and Nottingham, by Thomas Playfair, M.D., and Thomas Slaney, Esq., and the reports of the Commissioners of the Supply and Filtration of Water, on the Obstacles to Improvement in the Structure of Buildings, on the Cleansing of Streets and Buildings, and on the application of Reforms. The Second Report of the Commissioners, was presented to Parliament in February, 1845. It treats briefly of the Causes of Disease, and at considerable length of Remedial Measures. It is followed by a Report on the State of Birmingham and other towns, by E. A. Slaney, Esq., Commissioner of Bristol and other Towns, by Sir Henry T. de la Beche; a Report on the State of Large Towns in Lancashire, by Dr. Lyon Playfair; and a Supplement containing information on sewers, lodging-houses, and other matters connected with the inquiries of the Commissioners.

We have thus briefly stated the origin and progress of this important investigation into the sanitary condition of the population of Great Britain, chiefly indeed of the labouring and poorer inhabitants, but extending indirectly to all classes.

Other agencies for improving the physical condition of the labouring classes, and of the poor are among those the 'Health of Towns' Association, of which the Committee includes noblemen, dignitaries of the church, members of parliament, and other gentlemen. They have published various Reports on the Unhealthy Towns, their Causes and Remedies, delivered at Crosby Hall, London, by William Augustus Guy, M.B., Physician to King's College Hospital; a Lecture on the Unhealthy Towns, its Causes and Remedies, delivered Dec. 10, 1845, at the Mechanics' Institute at Plymouth, by Vicecorm Ebrington, M.P.; and a 'Report of the Committee to the Members of the Association, on Lord Lincoln's Bill.' (Lord Lincoln's Bill was introduced into Parliament at the close of the session of 1845.)

These important inquiries have proved by undeniable evidence, that the districts inhabited by the labouring classes, and often by tradesmen, in large towns, in many small towns, and in several parts of the country, are in a very noxious state, from want of drainage, want of cleanliness, imperfect ventilation, deficiency of water, and density of population; the consequences of which are great frequency of sickness, and excessive destruction of human life. Typhus fever, cholera, consumption, scrofulous and other chronic complaints, mostly arising from causes which might have been prevented, are found to exist to an extent which it is difficult to comprehend. The causes of sickness are generally most numerous and most intense in the crowded districts, and the mortality is found to be, with few exceptions, in proportion to the density of popula-

The average annual mortality in England is 3 per cent. in Whitechapel, but only 2 per cent in St. George's, Hanover Square. In the district of Bethnal-Green, 57 houses, on an average, were found to contain 580 persons; and in some of them the population reached 600 or more.

Of fifty towns which were visited by direction of the Commissioners, only eight were found to be in a tolerable state as to drainage and cleansing; and as to the supply of water the reports were still more unfavourable.

The annual average mortality in England is 2.07 per cent., or 1 in 45. In healthy districts it is 2 per cent., or 1 in 50. In the metropolis the deaths are 1 in 39; in Birmingham and Leeds 1 in 37; in Sheffield 1 in 32; in Bristol 1 in 32; in Manchester, 1 in 30; in Liverpool 1 in 29. In Brussels they have been found to be 1 in 34. The mortality was found to be greatest in cities than in any other town in England. By the return made to the Town Council of Liverpool in 1841, by their surveyors, it appears that there were then 2398 courts, which contained a population of 63,345 persons. In these courts 1300 were occupied by persons, whose persons were crowded in the same manner as in the metropolis.

The average of the whole country is 3 per cent., and in any city, town or village it is only 2.3 per cent. The sanitary condition of the metropolis for 1824, the age at death of the city, the tradesmen, and the working classes, who died at the age of 15 and upwards, Mr. Guy ascertained that the average lived 39.8 years, and the working classes 48. In 1844 the deaths in the metropolis were 50,423. If the rate of mortality had been 1 in 60.
instead of 1 in 39, the deaths would have been only 40,146, thus giving a saving of 10,278 lives in one year. From a Report of the Registrar-General it appears that out of every million of inhabitants 27,000 die every year in the large towns, and almost 3,000,000 in the smaller towns.

The large towns have already begun to make improvements. The improved drainage in twenty streets of Manchester has been found to diminish the annual number of deaths by more than 20 in every 110: and similar results of structural improvement have followed in other instances.

The loss of life, and the pecuniary charges consequent upon it to individuals and the community, are not the only considerations to be adverted to. Not only the sickness which precedes death, but the sickness which is cured, renders the suf-ferers incapable of following their usual occupations, and obliges them and their families to seek relief from the parish, and from public charity. It has been shown that pecuniary saving would result from sanitary improvements to such an amount as to justify the action of the legislature, if it were only from motives of public economy.

The power vested in courts-levy by ancient usage is resorted to in a few towns for the abatement of minor nuisances. Mr. Coulthart gives a detailed description of the various matters which have been taken cognizance of by the leet jurys at Ashton-under-Lyne, Rochdale, and Wigan. But the only practicable body to deal with them are the local authorities. In most places, however, the exercise of these powers has fallen into desuetude, even where the courts still continue to be held.

The measures necessary to be adopted in order to improve the sanitary condition of the inhabitants of the southern and central populous districts are comprised under the following heads:—

1. Drainage, including house and street drainage, and the drainage of any place not covered with houses, yet influencing the health of the inhabitants.

2. The paving of streets, courts, and alleys.

3. Cleansing, comprising the removal of all refuse matter not carried off by drainage, and the removal of nuisances.

4. A distinct supply of water for public purposes and domestic use.

5. The construction and ventilation of buildings in such a manner as to promote rather than injure the health of the inhabitants.

The Second Report of the Commissioners gives Thirty Recommendations to the legislature, each of which is preceded by the reason on which the recommendation is founded. We can only afford space for a summary of these recommendations which follow:

No. 1 recommends that in all cases the local administrative body shall have the special charge and direction of all works required for sanitary purposes, but that the crown shall possess a general power of supervision.

No. 2 to 11 relate to Drainage: surveys and plans; definition of area for drainage by the crown; appointment of surveyors; investigations by authority of the crown, on report; assessment of lands; priorities; no sale of full or half interest in the entire area by one body; purchase of rights of mill-owners and others; construction of sewers, branch sewers, and house-drains; rating of lands when house is let in separate apartments, or otherwise, for income or rate; and no more than once a quarter, or when the yearly rent is less than 10l.; providing of funds by the local administrative body, distribution of cost among the owners of the properties benefited, and charge of house-drains on owners of which they belong; power to raise money, and provision for gradual liquidation of debt incurred.

No. 12 recommends that the Paving be under the same management as the draining; but that it be performed by the local public officers.

No. 13, 14, and 15, relate to the Cleansing of all privies and cess-pools at proper times and on due notice; removal of large collections of dung; and abatement of nuisances arising from noxious exhalations from factories.

No. 17 to 21 relate to the supply of Water, in sufficient quantities not only for the domestic wants of the inhabitants, but also for cleansing the streets, securing the sewers and drains, and the extinction of fires; purchase of the interests of water-companies, and placing the management of the supply of water under the local administrative body; the establishment of water-meters, the making of the rate according to the water used, and especially recommending that the supply of water in the mains be not only constant, but as high a pressure as circumstances will permit.

No. 22 recommends Regulations for Buildings, including power to raise money for the purchase of property, for the purpose of opening thoroughfares, and widening streets, courts, and alleys; prohibition of use of cellars as dwellings, except when they are of certain dimensions and properly ventilated; provision for building all new houses with proper privies, and for a good system of ventilation in all offices for public assembling and reposing especially in churches.

Nos. 27 and 28 recommend that power be given to the local administrative body to compel landlords to cleanse houses duly reported to be in a nuisance state from filthiness—and that power be given to the magistrates to license and issue rules for regulation of lodging-houses for the reception of vagrants, trampers, and persons of similar wayfaring habits.

No 29 recommends the appointment of a medical officer in each town or district, who shall report periodically on the sanitary condition of such town or district.

No. 30 establishes the establishment of Public Walks, and that the local administrative body be empowered to raise the necessary funds for the management and care of the walks when established.

A large portion of the Report of the Committee on Lord Lincoln's Bill, before mentioned, is occupied with showing that the supply of water, wherever practicable, should be constant, not only in the main pipes, but in the branch-pipes, thus doing entirely away with the water-buts; and contending that in most cases such a constant supply is not only more economical, and the water runs away but in the highest degree to the cleanliness of houses in crowded districts, and consequently to the health of the inhabitants.

PUBLIC POLICY. This expression sometimes occurs in the reports of these inquiries, and signifies nothing more than that the law should be consistently carried into effect. An example will best explain how they are applied. One man may agree with another for a certain sum of money, that the man is to carry up to any premises in which he carried on some trade, art, or business, and agree that he will not carry on the same within the limits of England. The object of the bargain is to secure to him who pays his money, all the benefit which might otherwise result from it. But he who has received the money may happen to break his contract by commencing the same trade, art, or business in a distant part of the realm, as at the Land's End or Newcastle-on-Tyne, or in the original place, or in another business being supposed to be in London. Now if an action were brought on such a contract, it could not be maintained, and the reason would be that the contract was against public policy, which would be explained to mean that the public ought not to be deprived of a man's services by such an unreasonable contract. Yet it would be said that if the contract were that the man who received the money should not exercise his trade, art, or business within a certain limited distance of London, the contract would be valid. This would imply that the public of a given district may be deprived of a man's services in order that another individual may have an advantage which it did not possess before. It would be a more consistent conclusion to declare the contract altogether invalid, if reasons of public policy, as they are called, are to be taken into the account in forming a judgment of the validity of the contract, or, by a libel, to be taken into the account in forming a judgment of the validity of the contract, or, by a libel, to be taken into the account in forming a judgment of the validity of the contract. It would be a more consistent conclusion to declare the contract altogether invalid, if reasons of public policy, as they are called, are to be taken into the account in forming a judgment of the validity of the contract, or, by a libel, to be taken into the account in forming a judgment of the validity of the contract. It would be a more consistent conclusion to declare the contract altogether invalid, if reasons of public policy, as they are called, are to be taken into the account in forming a judgment of the validity of the contract, or, by a libel, to be taken into the account in forming a judgment of the validity of the contract.

Still it may be said that there are contracts which ought to be declared void for reasons of public policy, or, to use a more correct expression of Lord Hardwicke, reasons of public utility (Earl of Chesterfield, &c., versus Sir Abraham Jannsen, 2 Ves. 155). Lord Hardwicke observes, 'Particular persons in contracts shall not only transtact bond fide between themselves, but shall not transact mold fide in respect of other persons, who stand in such a relation to either as to be affected by the contract or the consequences of it; and as the rest of mankind besides the parties contracting are concerned, it is properly said to be their interest to have the contract prohibited. A merchant is sued for a spiritium contracted to be given for preferring or recommending to public office or employment; none of the parties are defrauded, but the persons having the legal appointment of those offices are thereby prevented from receiving the benefit; if the case be one in which the person recommended is a fit person, and no damage is caused by the bargain to give a premium.'

P. C. S. No. 143

VOL. II.—A N
But though it may be urged, as Lord Hardwicke would argue, that damage to the public service may be caused by such bargains, and we may admit that generally it would be so. it cannot be completely ascribed to the public, because perhaps not the best ground on which to assume the invalidity of such bargains. If the person who has the appointment to a place in the public service receives the power of appointment, and if it is not clear that he is not entitled to profit from the appointment, any premium that be might bargain for would clearly make the bargain illegal; because the thing is not a subject of bargain or sale. The same reasoning applies to any other person whose recommendation may help another to an office, by the supposition the office is not a thing that can be the subject of bargain and sale. (Comparo Inst. tit. 10, 2.)

PULICA RIA, a genus of plants belonging to the natural order Asterolaeae. It has an involucre late imbricated in few rows. The pappus in two rows, the outer one short, cupulate, membranous, and toothed, the inner one plume.

P. lindleyi, is found in the average of the autumn. It is a slender, yellowish plant, with a slender stem. The leaves are linear, and the flower-heads are small, and the flowers are white. The flowers are numerous, and the fruit is a small, round, black, ribbed, and spiny. It is found in moist sandy banks in Great Britain.

PULMONA RIA (so named from its being supposed efficacious in disorders of the lungs, or from the spots on the leaves resembling those on some diseased lungs), a genus of plants with the natural order Cynoglossae. It is a small genus of herbs found in the north of Europe. The flowers are white, and the leaves are linear. The plant is found in damp places in Great Britain.

PULMONA RIA, by its depress.

PULMONA RIA (so named from its being supposed efficacious in disorders of the lungs, or from the spots on the leaves resembling those on some diseased lungs), a genus of plants with the natural order Cynoglossae. It is a small genus of herbs found in the north of Europe. The flowers are white, and the leaves are linear. The plant is found in damp places in Great Britain.

PURCHASE, which is corrupted from the Latin word Perquisatio, is defined by Littleton (1:12) to be the possession of things, where the person that buys them is an agreement, unto which possession he cometh not by title of descent from any of his ancestors, or of his cousins (consanguine), but by his own deed. Purchase as thus defined comprehends the purchase of land by deed or agreement, and not by descent; it is not a complete description of purchase, as now understood, for it omits the mode of acquisition by will or testament, which however, is comprehended when land is bought by title. This species is a herbaceous plant with spotted leaves and terminal corymbous racemes of flowers.

P. officinalis, Langwort, has ovate leaves, roundish or cordate, the upper leaves oblong. The root is thick and black. The corollas are red before expansion and then purplish. The whole plant is more or less hispid. It is found in the woods and thickets of England, and is native of Europe and the Caspian. The leaves, which are the parts of the plant recommended in medicine, have no peculiar smell, but in their recent state manifest a slightly astrigent and mucilaginous taste,—hence they are supposed to be demulcent and pectoral, and to have a cathartic effect in consumption. All these plants contain nitre in considerable quantities, and when burnt this species yields one-seventh of its weight in nitre. In the north of Europe it is eaten as a potherb, and according to How it was brought to table in Scotland.

P. angustifolia has all lanceolate leaves. It is difficult to distinguish from the former species, but is more pubescent, and has narrower spotless leaves. The corolla is purple, and the flowers are white. The leaves are linear. All the species of Pulmonaria are pretty plants when in blossom, and are desirable for gardens on account of their early flowering. They are very easily cultivated, and will grow in any common garden soil; they are readily propagable by division. Most of these species grow well under the drip of trees and in moist situations.

(Don, Gardiner's Dictionary, Babington, Manual of Brit. Flora, and Dictionary of Botany.)

PUNCTUM CAECUM, in the eye, is the part of the surface of the retina which is immediately adjacent to the optic nerve. At this point the optic nerve leaves the eyeball and receives impressions from the rays of light which, coming from external objects and converging there, should form images of those objects: consequently the part contributes nothing to the perception of images. Its existence in each eye is proved by a well-known experiment, which was first made by Marriotte — on a dark ground, as a black board, in a vertical position, place on a level with the eye a white paper, and at such a distance that it is against public policy might be determined on some legal principle, which should not require the introduction of the principle of determining that a contract shall be void because it is prejudicial to the public. (Mailan v. May, M. & W. L. 662.) If the validity of a contract is to be determined on this principle, it is very difficult to say what limits must be set to its application.

PYRANE, a genus of Gasteropods, which includes two species, lived near Hadrian Bridge. (Brown. Man. Geol. Trans.)

PYRETHRUM (from πυρ, fire, because of the hot taste of the root), a genus of Composite plants belonging to the tribe Asteraceae. It has a hemispherical involucre, the receptacle flat or convex. The fruit angular and winged. The papus is an elevated membranous border.

P. Parthenium, Feverfew, has stalked pinnate leaves, with ovate or oblong segments, the base of a hoary green, the leaflets inflexed to ovate decurrent and cut. The flower-heads are erect, about half an inch broad, with a convex yellow disk, and numerous short broad abort 2-ribbed white rays, often wanting, sometimes multiplied, and the disk being obliterated constituting a double flower. The whole plant is bitter and strong scented, reckoned tonic, stimulating, and anti-hysteric. It was once a popular remedy in ague. It is said that the odour is peculiarly disagreeable to bees, and that these insects may be easily kept at a distance by carrying a handful of the flower-heads. It is common in many parts of Europe and in England.

P. vulgaris has pinnate leaves, in numerous apical pointed segments. A branched stem, solitary head, the involucral scales lanceolate obtuse; the fruit rugose with two round glandular dots on the external face just below the beak of the nut-like seed. It is found in fields and waste places in Great Britain.

P. argyranthemum has sessile doubly pinnate leaves, with fleshy segments, convex above, keeled beneath. The stem differs from the others. Sulphur is deposited on the root, and this is followed by 2 elongated glandular spots on the external face, just below the elevated lobed border. It is found on sea-shores in Great Britain.

Plant. See the botany of Spain, once much esteemed as a salve and resort to it for relief in toothache. Grew says that when the root of pyrethrum is chewed, it makes a sensible impression on the tips, which continues like the fumes of brandy. It possesses more powerful effects on the stomach. When extracted, the scirr oil contained in the root is said to be serviceable in cases of palsy, and when cutaneous action is required, as a liniment. Ainslie says it is administered in typhus fever by the Indian practitioners. (Burnett. Outlines of Botany. Lindley. Flora Medica. Brevignon. Manual of British Botany.)

PYRNA, a fossil genus of Echinodermata proposed by De Moulina for the Echinoidea degrassi of the green-sand.

PYROGEN is a term very recently applied to the electric fluid, derived from the Greek word πυρ, fire. The views of Mr. Lake, who first proposed it a short time since, are novel, and certainly deserve attention. He maintains that there is no name because there appears to be a degree of indeterminate ness in the terms electricity, electric fluid, &c., and hoping that he has produced sufficient evidence in support of its maintenance. He considers that the term 'pyrogen' might be advantageous. If this or some similar name were adopted. Electric might have been used, but as the fluid has no more connection with water (aqueous) than many other substances possessing like properties, he has chosen to propose an entirely new name; and as it bears the greatest resemblance to fire, and seems to have a most intimate connection with that element, the word 'pyrogen' is submitted.

He maintains, in the first place, that as electricity produces mechanical effects upon matter (for instance, reduces the strongest oak to splinters, and some substances into powder, removes large blocks of stone out of their places, drills holes in metal vessels, and occasion earthquakes), it must be matter, as nothing of an immaterial nature can produce mechanical effects upon material bodies.

He also says, to declare the material nature of electricity from the above considerations, and a simple experiment with a galvanic arrangement, consisting of a pair of plates 2 inches by 4 inches, in a half-pint drinking-glass, in which was placed, at the bottom, a solution of copper, joined together and insulated by non-conducting materials. From this arrangement and the wires being insulated, the fluid could not have proceeded from without, and he considers that it was developed on meeting the polar plates, which could not have been from a new chemical arrangement of the liquid matter, and, as the water the only ingredient actually decomposed, the fluid must enter into the composition of it together with oxygen and hydrogen; which view receives much support from the fact that water is formed on the combustion of these gases by the electric spark.

A difficulty however arises on this point, for those gases may be exploded, and the fluid rendered visible whilst effecting the decomposition of air, and the union of the oxygen obtained from it with the hydrogen of the burning body; and in proof of this theory advances the facts, that in all the various methods adopted to obtain fire, it is generated by electric excitation (except when obtained by the combustion of a burning glass) and in damp weather, when the atmosphere is deprived of the electric fluid, held in suspension by it at other times to a very considerable extent. fires and lights burn very dull.

In further support of this theory he offers the following explanation of the ingeneous experiments of Messrs. Tyllock, Gann, and Mackrell on the ignition of metals in acid solutions. It may be well to premise that the acid solution through which the electric currents were passed was composed of one part sulphuric acid and ten parts distilled water, in a common drinking-glass that held about a pint.

1. Experiment 1. Fine iron wires (No. 26) were attached to the terminal wires of the battery. The positive wire was first immersed in the solution, and the circuit was completed by the immersion of the negative wire. The latter burned with a beautiful reddish flame. This would seem to result from the decomposition of the hydrogen, which, when released at the negative pole, on the decomposition of the water, and the oxygen of the acid having a greater affinity for these than for sulphur, the acid is decomposed, the oxygen then on the negative electrode, and the released gas combining with the hydrogen and pyrogen, combustion (ignition) takes place. When the experiment is reversed, and the negative wire first brought into the solution, the circuit being completed by the positive wire, the latter becomes red-hot to the extent of an inch and a half under the solution. This resulted from the accumulation, as it is called, at the pole of the unconnected piles, rendering the pyrogenic current from first to last minute during its continuation. No flame appeared at the positive pole, there being no hydrogen present, all that obtained having escaped at the negative electrode.

2. Experiment 2. A platinum plate, an inch long by half an inch wide, being attached to the negative wire, and a small iron wire at the positive, the platinum being first immersed in the solution, and the circuit completely completed, the positive wire, it became red-hot; an inch and half under the solution, as in the last experiment, and from the same cause; but when it was only brought into contact with the surface of the solution it fused, which was prevented when it was immersed.

3. Experiment 3. When the iron wire was placed at the negative end of the battery and the platinum at the positive, the platinum being first put into the solution and the circuit completely completed by the positive wire, it became red-hot; an inch and half under the solution. This resulted from both oxygen and hydrogen being present at the negative pole, as in the first experiment.

4. Experiment 4. A fine copper wire was attached to the positive terminal, and a platinum wire to the negative. The platinum being as usual first immersed, and the circuit completed by the insertion of the copper wire, the latter was heated an inch under the water. The cause of there being no flame is the same as in the former experiments, for the copper wire being at the positive electrode, no hydrogen was present to produce it. But when the experiment was reversed, and the copper wire placed at the negative termination and the platinum at the positive, the latter being first immersed and the circuit completed by the former, the copper or negative wire burned with a bluish flame, oxygen and hydrogen being, as before, present that problem.

5. Experiment 5. A slip of zinc was used instead of copper wire, and with the same result; for when placed at the positive termination, and the platinum at the negative, and the latter being first immersed, the zinc was heated to a suffusion of the liquid, but the water was placed at the negative, the platinum at the positive, and the latter first immersed, the zinc at the negative burned with a purple flame, hydrogen being present, as before, at that pole.

6. Experiment 6. With platinum at the positive and sulphur of antimony at the negative, the platinum being first
impressed, the antimony or negative electrode fused and inflammation, depositing on the glass and surface of the solution an orange-coloured powder resembling Kernes' mineral. When the sulphur was at the positive, the platinum at the negative and the first mixture of the solution, when further iron was added, were given off by the sulphur, but it was not ignited, for, as in the preceding experiments, there was not any hydrogen at the positive point.

"Experiments. 7. When an iron wire was fixed to the positive, and a charcoal point at the negative, the iron wire being first immersed, immediately the charcoal touched the solution it became very brilliant. But when the experiment was reversed this did not occur; for when chemical charcoal was at the negative hydrogen was present, but not when at the positive." Mr. Lake considers that in these experiments the ignition could only have resulted from the presence of electricity and the power it possesses of causing matter to vary its form; and that they particularly evince its property of ready combination with oxygen and hydrogen and formation of flame.

This discovery will produce an important revolution in chemical science; for if electricity enters into the composition of water it must also be a constituent part of every body into the formation of which water enters. Mr. Lake also asserts that the fluid is a component part of oxides; that, in fact, it is the medium by which the union of oxygen with its bases is brought about, and that it was by its abstraction Sir H. Davy reduced potash, magnesia, and other substances. Mr. Lake also believes that it is a most important ingredient in acids, and that it forms ozone by combining with oxygen. [O'zone, P. C. S.]

"Water," he says, "is the medium by which many chemical substances amalgamate, and the decomposed oxygen of matter produced. Many bodies may be placed together, ground together, and every device adopted to produce chemical action among them in vain; but let only a little water be introduced, and immediately the desired effect is produced; the substances are in part, or entirely, decomposed, and the matter of which they consisted assumes altogether different forms, and acquires different properties.

"Pyrogen acts in a similar manner, and by its abstraction or combination, matter enters into the place. Thus it is found that by discharges of it in common air nitric acid is produced; and when mercury is placed in contact with a solution of ammonia, and negatively electrified,—that is, the pyrogen drawn from it,—it expands in volume and becomes a soft solid. But the presence of pyrogen, which returns to it on breaking communication with the galvanic battery, destroys the affinity between the mercury and ammonia. Therefore, when the product of this experiment is exposed to water, the latter is decomposed by it, giving out hydrogen, whilst the former absorbs oxygen and pyrogen, leaving mercury and a solution of ammonia. If exposed to air this is also decomposed, and oxygen and pyrogen are absorbed.

Potassium, sodium, calcium, barium, strontium, and many other bodies, are obtained by the abstraction of pyrogen from their solutions, which means the affinity between them oxygen is destroyed, and they separate. But, as in the case of the amalgam of mercury and ammonia, and from the same cause, as soon as they are exposed to air or water, they absorb oxygen and pyrogen, and return to oxides.

The chemical affinity of pyrogen and oxygen appears to be less with ammonia than potassium, sodium, calcium, barium, strontium, and some others; for when any of these are united as an amalgam with mercury, and exhibited in this state to ammonia, an amalgam of mercury and the bases of ammonia is formed, and the fixed alkalies or earths are reproduced, the first amalgam having absorbed the pyrogen and oxygen of the second.

In the experiments of Messrs. Schönhobel and Gnaux with ozone, Mr. Lake deduces that zinc, nitrogen, and hydrogen, to perhaps iron and copper, are not simple bodies. He draws this conclusion as regards the metals from the different colours of the flames in the experiments of Messrs. Pollack and others on the ignition of metals in acid solutions, and, in respect to zinc, the additional singularity of the smell produced by it when used as an electrode in obtaining ozone. As to the opinion concerning the gases, he arrives at it from ozone (which he considers to be a compound of oxygen and the electric fluid) being obtained from them. [Ozone, P. C. S.]

One other point remains to be noticed, namely, the connection of the electric fluid with the acids. Concerning this our author says,—"Pyrogen enters into the composition of carbonic acid, which may be generated by the passage of a current of the former from charcoal (that is, carbon) points. By this means the oxygen of the atmosphere unites with the carbon, which has the greatest possible affinity for it when pyrogen is present in motion." Again, "Carbonic acid can be dissolved by the abstraction of pyrogen from it, by exhibiting to it other substances which have a greater affinity for the latter.

"When water decomposes ammonia, the oxygen of the amalgam of the bases of ammonia and mercury, there is a most decided decomposition of this acid and formation of carbonaceous matter."

"Pyrogen also enters into the composition of nitric acid, which is produced on passing sparks or discharges of it through atmospheric air. . . . . By analysis, pyrogen may be obtained from nitric acid by using a solution of the latter in the experiments of the igniting solutions in acid solutions. [Ozone, P. C. S.] In a similar manner it may be procured from muriatic, phosphoric, and many other acids.

These views of this subject certainly explain many phenomena going on around us, the causes of which have hitherto been inexplicable. Thus, in one of his papers Mr. Lake says that the development of carbonic acid by plants results from the electric fluid, which is in a constant state of circulation, uniting with the carbon of the plants and oxygen of the air. He might have gone farther, and shown, upon his own theory, that plants not only make use of the fluid in this manner, but that they actually produce it from the water with which they are supplied, as is proved by Pouillet's experiments with insulated corn-plants.

The subject being new, we will not enter into further details; but the above is the substance of what has appeared concerning it.

PYROLA. [WITTK.-GREEN, F. C.] PYXIDIFULCA, an obscure genus of fossil Inversoria. (Ehrenberg.)

QUADRATURE. Not thinking of this Supplement, we inserted in the article Trisection, P. C., the extension given to the approximate arithmetical quadrature by Mr. Rutherford (Phil. Trans., 1641). With this reference, we take the opportunity of saying that we have re-examined the numbers, and find them correctly printed.

Strange as it may seem, this problem of the quadrature of the circle still engages attention: and persons are found to believe that they have attained even the arithmetical quadrature. It has been stated in foreign newspapers within these few years that the British government does offer, and always has offered, a large reward for the solution of this problem. This, we need hardly say, is a complete mistake: the government never at any time offered one farthing for the quadrature of the circle. The only problem for the solution of which any reward was at any time offered, was the practical mode of finding longitude: and even this offer is now retracted; rewards having been, in fact, received by several persons. Should this article fall into the hands of any, at home or abroad, who are working at any mathematical or astronomical difficulty under the impression that our government is pledged to remunerate them in case of success, they may rest assured that their information is incorrect, and that they will find it to be so on inquiry.

QUEEN CONSORT. [Queens, P. C.]
QUICKSANDS are those masses of loose or moving sand which are formed on many sea-coasts and generally at the mouths of rivers: those of the Nile and Senegal are among the most remarkable for these accumulations. The sands are generally conveyed by the rivers from the interior of the country, and being at first arrested by the waters of the ocean, they become, by the action of the wind and tides, moveable bars, which are very dangerous to shipping. The loose sands on the coasts are, when dry, driven by winds over the land, which they then cover often to a considerable depth, overlying the fertile ground and occasionally entombing whole villages: the coasts of Cornwall in England and of Jutland in Denmark are particularly subject to these encroachments; and it is stated that, in the latter country, there are vast beds of sand so loose as to be incapable of supporting the weight of a man. In Greenland there is a chain of ice-hills between two promontories of moving sand, which is driven by the winds far out to sea.

The sand of Bagshot Heath, which rests on London clay, is in many places, at a few feet below the surface, saturated with water so as to constitute a perfect quicksand: and, on the borders of Oman, in Arabia, there was discovered by Baron von Wrede a remarkable quicksand, which is said to be more than 60 feet deep.

RADIATA. [RATED OR RADIATED ANIMALS, P. C.]

RADIOLAS (from radiana, little ray, in allusion to the rayed capsules), a genus of plants belonging to the natural order 100, is of 4 species, placed beneath the Family 100, deeply tridif. There are 4 petals, 4 stamens, 4 capsules, with 8 cells and 8 valves.

R. radiata is the only species of this genus. It is the Radiolaria is well known to botanists, and is a British plant. The stem is from one to two feet high, repeatedly forked, with solitary flowers in the axils as well as at the extremities of the branches. The flowers are small and white; the capsules light brown and slightly depressed; the sepals deeply and acutely 3-angled, connected below into a tube. The seeds of this very small plant should be sown in a moist situation where they may afterwards be scattered to their advantage.

(Balhington, Manual of British Botany; Don, Gardener's Dictionary.)

RAIA, a genus of cardinalline fishes, established by Linnaeus, and since much subdivided by ichthyologists. The rays differ from the sharks in being horizontally flattened so that their bodies with their broad and flabby pectoral fins resemble large expanded disks. The eyes and spiracles are placed above the mouth, nostrils and bronchial apertures below. The dorsal fins spring from the tail. The common skate and the ray are familiar examples.

The following are the principal sub-genera into which this genus has been divided:

1. RAIA has been divided into two sub-genera:

   1. RAIA has been divided into two sub-genera:

   a. Rays with short and rather thick tails, and having the disk of their bodies nearly circular. Their teeth are small and sharp. The torpedos are remarkable for the electrical apparatus with which they are provided; it is seated in the region between the pectorals, head, and branchia. Fishes of this genus are rare in the British seas, but common on the coasts of Southern Europe.

   b. RAIA. The tail of the typical Ray is slender, and bears two small dorsal fins towards the extremity, with sometimes an imperfect caudal fin. The disk of the body is rhomboidal; the mouth is armed with slender fleshy-set teeth arranged in quinquelocular rows.

   2. The Sting-rays, which have a slender fan-like tail armed with a sharp serrated spine by which the fish can inflict severe wounds; hence its popular name. The head is enveloped in the pectorals; and the teeth are slender and arranged as in RAIA proper.

   3. Myliobatis. Tail very long, armed and bearing a small dorsal fin; head projecting from between the pectorals, which are very broad, and the head and arranged like stones in a pavement. The Whip-ray belongs to this sub-genus.

   4. Cephaloptera. Tail also armed, and bearing a small dorsal fin, but the head is curiously truncated, and is placed between two horn-like processes of the broad pectoral fins, giving the creature a somewhat unprepossessing and incompleat aspect. The teeth are small and very slender.

RAILWAYS. [TRANSIT, RAILWAY, P. C. S.]

RAIMBAULT, ABRAHAM, one of the most distinguished English line engravers, was born in London in 1776; his father was a Swiss by birth, but he settled in England at the early age of twelve, and never afterwards quitted it; his mother was the daughter of an English farmer in Warwickshire. When an infant, Raimbach escaped from one of those rare but awful accidents which occasionally happen through the negligence of nurses; he fell from the arms of his nurse from a second-floor window; but his life was saved, partly by the influence of his long clothes, and partly by the fall being broken by some leads below. The girl from whose arms he fell seized with such a panic that she rushed out of the window, and was never heard of by any of the Rainbuchs afterwards.

Raimbach was educated in Archbishop Tenison's library-school, where he was the fellow-pupil of the late Charles Mansion; he was also apprenticed in a shop of 4 years' standing, and was engaged for a long period in the arts, and his father apprenticed him in 1789 to a Hall, the engraver; Sharp and J. Heath had both declined to take him. The first work engraved by the young apprentice was a project upon the anatomy key to Copley's Death of Chatham in the National Gallery, where the print also is now hanging, framed and glazed, beneath the picture. After his term of apprenticeship was over he entered as a student in the Royal Academy, anxious to qualify himself in every way for his art; he at the same time did what work he could for the booksellers; but he then devoted himself to painting with great assiduity in earning as much as thirty shillings a week. His first patron was a bookseller of the name of Stockdale. But, by his general attention and assiduity, he was enabled to unite the profession of a miniature painter and portrait painter, and he prospered in a short period so well in both, that he was under inofficious of giving one of them up, and confining himself to the other. According to his own account, he was influenced not a little in his choice by the uniform difficulties he met with in satisfying his sitters with his miniatures. All had opinions of their own about their looks, which it was necessary to attend to; he therefore gave up portrait painting, as he found engraving a much more independent art.

In 1802, through some prints he executed for Smirke and Forster's illustrated edition of the Arabian Nights, he was in such circumstances as enabled him to take advantage of the temporary peace, and he paid a visit to Paris to view the great galaxy of works of art which the victories of Napoleon had collected together in the Louvre. He has himself given a long account of this tour in his autobiography, published by his son. In 1805 he married and established himself in a house of his own in Warren-Street, Fitzroy-Square, in which he lived twenty-five years, and executed all his great works; the house was given to him by his wife, and his father died in the same year; in 1807 he lost his mother also. In this year he made the acquaintance of Wilkie, and soon became that painter's most intimate friend. In 1812 he became Wilkie's engraver, supplanting Burnet, who had already engraved some of Wilkie's pictures in an admirable manner. The chief reason of Wilkie's breaking with Burnet appears to have been what he considered the smallness of his interest in the prints—one-third of the profits. Burnet would not allow more than this, and Wilkie left him for Raimbach, with whom, however, he was contented with the same arrangement; and, indeed, he himself afterwards voluntarily reduced his share to one-fourth of the profits. The first fruit of this partnership was the celebrated print of the 'Village Politicians.' This print however, owing, it appears, to the indifference of print-sellers to anything out of the ordinary way of business, at first went off slowly; but eventually the sale was large and steady, and a proof, of which there were 274, has sometimes been sold at auction for fourteen or fifteen pounds. The first print was published in 1816; after which Wilkie and Raimbach made a tour together in the Netherlands. The rest appeared in the following order: 'The Cut Finger,' 'The Errand-Boy,' 'The blindman's Run,' 'The Winning of the Child,' 'The Beadle,' and in 1836, 'The Spanish Mother and Child.' The last prints, compared with the 'The Village Politicians' and 'The Rent-Day,' were very unsuccessful speculations, and Raimbach thus accounts for the fact in his autobiography: For the long terms of more than twenty years the prints from Wilkie's pictures had enjoyed an almost unprecedented popularity; and it can scarcely be held as a matter of reproach to the public if, after so long a period of favour in one direction, the desire of some sort of change of object should be entertained. The great talents of Edwin Landseer had been already well appreciated, when his picture of the Monks of Bolton Abbey appeared, and placed his reputation on a still higher elevation. Secured by Cousin's admirable mezzotinto from it, there followed a rush in the track thus so auspiciously commenced, and the new lights (as in Alahdin's lamp) were preferred to the old. Raimbach an assistant, executed the whole of the plate himself. 'The Rent-Day' cost him two years and a half of incessant labour. His prints are very masterly works, and possess every quality but that of being held in the highest estimation in very easy circumstances. His autobiography was published by his son in the same year, under the following title:— Memoirs and Recollections of the late Abraham Raimbach; including a Memoir of the late Mr. Jean-Philippe Rameau, a very celebrated musician, equally distinguished by his compositions and by his art.
numerous writings on the science, was born at Dijon, in 1683. It may be presumed that he inherited a taste for music, for his father was so passionately fond of the art that he had his son educated at a very early age for the church profession, and obtained the organist's chair in the Sainte-Chapelle of the above-named city. He taught his children to play from notes before they could read from letters, and the success and rapid advance of his pupils, as far as relates to musical education, is manifested in the instance of his eldest son, the subject of the present notice, who when only seven years of age was thought an able performer on the harpsichord. He pursued the usual studies at college, where his knowledge was acquired without reluctance and readily; but an invincible desire, or instinct, as his biographer calls it, led him to music, to which he at length wholly devoted himself. At eighteen he set out for Italy, in order to complete his knowledge of the art to which his future life was to be dedicated, but proceeded no farther than Milan, where he became acquainted with a professor with whom he returned to France, and together they visited several of the principal cities, exercising their talents at each with pecuniary views. Soon, however, tired of a wandering life, that allowed him no opportunity for indulging in those speculative inquiries to which he was prone, he went to Paris, and there added largely to his stock of information. Afterwards he became organist of the cathedral of Clermont, in Auvergne, and continued long in that city, in which he wrote his 'Traité de l'Harmonie'; but not finding the taste for church music in proportion to his spirit in that town, he proceeded to the capital of France, where in 1722 he published his great work, and finally fixed himself. He was soon appointed organist of Sainte Croix de la Brestanerie, and in a very short time in writing numerous theoretical works, in compounding his harpsichord lessons, and in teaching. He did not distinguish himself in that line in which he was destined to excel till the year 1735, when, at fifty years of age, he published the opera of 'Hippolyte et Aricie,' the drama by the Abbé Pellegrin. The success of this provoked much professional envy, if not national discord, and a feud was raised among the admirers of Lulli (LOLL, P.C.) and Rameau, similar to that which in after times was caused by Gluck and Piccinni. [GLUCK, P. C.; PICCI, P. C.] The Prince de Conti asked Campra, the celebrated Maître de Musique of Notre-Dame, what he thought of the new work? He replied, 'There is enough of music in it to make six operas.' Till the production of Hippolyte, Voltaire alone had discovered Rameau's genius for composition. He previously gave him his tragedy of 'Samson' to set, and discerned the beauty of the music; but its performance was prohibited under the pretext that it was prostituted a sacred subject.

Of the many operas by Rameau, his 'Castor et Pollux,' produced at the Académie Royale de Musique in 1767, is the best known. Great success attended it; there were parts desired elsewhere, and it must always excite the admiration of true connoisseurs. A chorus in this, of Spartacus, 'Que tout genieus,' has but few rivals, in either ancient or modern theatrical music. Even M. Grimm, in his 'Histoire de la Musique,' gives it as an example of the merit of this composition. His 'Durandus,' his 'Zoroaster,' and other pieces, were equally successful. From 1738 to 1750 he produced twenty-one operas and ballets, besides harpsichord and other compositions; together with many theoretical and controversial works. His merit, long contested by envious rivals, was at length generally acknowledged. The king created for him the office of cabinet composer. Afterwards he granted him letters of nobility, and named him 'Chevalier de Saint-Michel.' The Academy of Dijon had previously received him among their members, and the city of Dijon, by act of its council and at the expense of its folly, the tax called 'La Taille.' He died in 1764, leaving a son and a daughter, and was interred with every mark of respect and distinction.

But passed his thirty-sixth year he commenced the employment in best known by his large and laboured work on the basso fondamentale, which he and his associates treat as a discovery. [Fundamental Bass, P. C.] But under other names the inversions of the perfect chord, or triads, became known long before, as far as relates to the invention of the basso continuo, the lowest part being called basso, or sonus fundamentales; and afterwards remarks that among the three sources from which rose the triode Harmonic, the lowest was called basses, or sonus fundamentales. But our limits do not allow us to go further into a subject which, to explain clearly, would fill many pages with arguments and examples. It is well considered by Dr. Burney, in his 'History of Music,' and by the same in Rees's 'Cyclopedia.' Rameau's style of writing is not remarkable for perspicuity. This was felt and acknowledged by his most zealous partisan, D'Alembert, who placed the first edition of his 'Principes de l'Harmonie,' 1742, in his produce, but was in the second edition, 1756, a great improvement. In the third, 1764, D'Alembert's work was introduced. In later editions the article has been omitted, and a much better one substituted. [Biographie Universelle; De Laborde, tome iii; Burney, vol. iv.]

RAMENGHI, BARTOLOMEO, called L. BAGNACAVALLO, from the place of his birth, Bagnacavallo, on the road from Ravenna to Lugo, where he was born in 1684. He was a pupil of Raphael, and one of his principal assistants in the Vatican; and after the death of his great master he carried the principles of his style to Bologna, and assisted to enlarge the character of that school. Raphael was his model and test of excellence, and he did not attempt to look beyond him, presuming that little was to be acquired by ordinary abilities from nature compared with what the works of Raphael afforded for imitation. Though possessing less vigour than Giulio Romano or Perino del Vaga, Bagnacavallo acquired more of the peculiar grace of Raphael's style, especially in his infants, and his works were much studied by the followers of Raphael. He made several copies of the works by Bagnacavallo in San Michele in Bosco, San Martino, Santa Maria Maggiore, and Sant' Agostino agli Sco- pettini, in Bologna. He died in Bologna in 1642, according to Scclari. He was a son of Bagnacavallo, who assisted Vasari in Rome, and Primitico at Fontainebleau, was the son of Bartolomeo Ramenghi.

(Berufflingli, Le Vite de' più insigni Pittori e Scultori Ferrare, this excellent work by Lanzi in MS, but it has been recently (1846) published for the first time at Ferrara by Domenico Taddei, after lying in MS. for nearly a century. Lanzi, Storia Pittori, &c.)

RAMMohan Roy was born about 1774, in the district of Burman, in Bengal, Hindustan. His paternal ancestors were Brahmins of a high order, and were devoted to the religious duties of their race, till about the beginning of the seventeenth century, when they gave up spiritual exercises for worldly pursuits. His maternal ancestors, also of high Brahminical rank, and priests by profession as well as by birth, uniformly adhered to a life of religious observances. Rammohan Roy was taught Persian under his father's roof, was sent to Patna to be instructed in Arabic, and afterwards, at the request of his maternal relations, went to Benares, in order to acquire the Sanscrit.

Rammohan Roy was a Brahmin by birth, and was trained by his father in the doctrines and observances of his sect; but his opinions seem to have become heretical at an early age. When about the age of sixteen, he wrote a manuscript called 'The Idealisation of the Vedas,' a work which, if not a manuscript containing the realisation of the idealism of the Ilius, this, together with my own sentiments on that subject, having produced a coolness between me and my immediate kindred, I proceeded on my travels, and passed through various countries, chiefly in Europe, but some beyond the limits of Hindustan. When I had reached the age of twenty my father recalled me, and restored me to his favour. Afterwards he says, 'My continued controversies with the Brahmins on the subject of their idolatry and superstition, and my interference with their custom of burning widows, and other pernicious practices, revived and increased their animosity against me; and my father, against the wishes of his family, left me again obliged to withdraw my countenance openly, though his limited pecuniary support was still continued to me.' His father died in 1803, and he then published various books a vindication of his conduct against the arm of the Brahmins in the native and foreign languages. 'The ground which I took in all my controversies was not that of opposition to Brahminism, but to a perversion of it; and I endeavoured to show that the tenets of Hindustan are long before the others of their ancestors, and to the principles of the ancient books and authorities which they profess to revere and obey.' In order to deprive him of caste, the Brahmins commenced a prosecution against him, which, after many years of litigation, was decided in his favour.

Of the body of Hindu theology comprised in the Vedas (VEDA, P.C.), there is an antient abstract called the 'Vedant, or the Resolution of all the Vedas,' written in Sanscrit.
Rammohun Roy translated it into Bengalee and Hindustanee; and afterwards published an abridgment of it for gratuitous circulation. Of this abridgment he prepared an English translation in 1816, the title of which states that the 'Vedant is the most celebrated and revered work of Brahminical theology, establishing the unity of the Supreme Being, and the law of propagation of the universe,' and that the movements of the defendants and the conveyance of the ammunition. The exterior and interior sides of the rampart are formed with sloping faces of earth raised in different degrees with that of the horizon: or they are retained by revetments of brick or stone, nearly upright, the exterior face of the rampart constituting the escarp of the ditch in front. The rampart is a flat place, this is divided into its length, into parts making salient or re-entering angles with one another; and these parts constitute the faces and flanks of the bastions, and the curtains which connect the latter together. Not more than 30 feet are allowed for the breadth of the terrepleins of the ramparts of outworks, measured from the foot of the parapets, in order that the enemy may not be able to form batteries for artillery upon these terrepleins. The terrepleins of all ramparts should have a small slope down, towards the interior, in order that the rain-water may not lodge on them, and that the defenders near the interior edge of the rampart may be effectually covered by the parapets.

The terreplein and the interior slope of a rampart, as well as the surface of the parapet, are generally covered with turf. A rampart whose exterior side is of earth, or without a revetment of brick or stone, might be easily ascended by an enemy at the time of an assault, and the parapet broken down in that case, would be planted in it for the purpose of impeding the progress of the enemy, might be easily destroyed by artillery, so that the place would be liable to be carried by a sudden assault.

The relief, or height, of a rampart is regulated by the occasional necessity of employing a fire of artillery from the rampart, and, at the same time, a fire of musketry made over the glacis by men stationed at the parapet, destroying the enemy's retiring in the ditch in front of the rampart: for this purpose a line of fire from the rampart should pass three or four feet above the crest of the glacis in its front, in order that the wind of the shot may not injure the defenders. The height of the parapet with its parapet may, therefore, be thus determined:—On a drawing representing a vertical section of the works let a line be drawn from the foot of the glacis, through a point taken at 3 or 4 feet above the crest of that work, and let it be produced till it cuts the interior slope of the parapet on the rampart: this intersection will give a point in the axis of a gun placed on the rampart, or a point a few inches above the sole of the embrasure, that is, about 34 feet above the terreplein of the rampart; and, because the artillery and the gunners are to be protected by the parapet, if 7 feet be added to the height of the terreplein of the rampart above the ground, the sum will be the required height of the crest of the parapet.

RAMPOUR, a town of Hindustan, in the district of Bara, province of Bengalee, and presidency of the N. Bengal, on the east bank of the Goolia river, in 28° 48' N. lat., and 79° E. long., 106 miles E. by N. from Delhi, direct distance. The town, at the time of the death of Fyzool Khan, a Rohilla chief to whom it had been secured by the peace of Lallading in 1774, was four miles in circumference and the centre of a flourishing district, but has since been greatly reduced. The district was granted to the nawab of Oude on the termination of the Rohilla war, and the town was ceded to the British in 1801, by whom it was transferred to the nawab of Rampoor, together with a small territory.

Rampoor is chiefly remarkable for the curious kind of fortification by which it is defended. A high thick hedge of bamboos faced on the outside by a prickly underwood of cactus and balsam. The entrances are by narrow passages, defended by strong wooden barriers. It is said to be an extremely effectual system against infantry, as neither cavalry nor infantry can be brought to act against an enemy whom they cannot see, and who is hiding from them among the close stems of the bamboos, and under cover of the almost impenetrable barriers. The town was almost totally destroyed in the summer of 1824, upon the retirement of the troops in the province. [Hamiton's 'East India Gazetteer'; Hieber's Narrative of a Journey through the Upper Provinces of India (1824 and 1825).]

Ramsay, Andrew Michael, generally known as the Chevalier Ramsay, was born at Ayr, in Scotland, the year 1686. He was educated at Edinburgh, where
chiby devoted himself to the study of mathematics and theology; the distinction he obtained as a scholar procured for him the appointment of tutor to the son of the Earl of Wemyss, at the University of St. Andrew's. Having entered into society among the teetotals of the Protestant faith, he went to Holland for the purpose of visiting a Protestant divine of the name of Poiret, who had obtained a certain celebrity as one of the leaders of the Quietist party. We are informed, in a recent controversy, of the fruits of which were an increase of his doubts and even an inclination to general scepticism on the great doctrines of the Christian religion. In this state of mind he determined on leaving France, and in 1749, he was exiled to the same, and was thus freed from the necessity of renouncing his faith. He went to London, where he was received into the society of the physician and political writer, the late Samuel Hume, who was his landlord, and whose house, afterwards, at 17, Millbank, was the birth-place of his son Ramsay, the well-known politician. He resided in London, with some of his disciples, and, at the end of the reign of the elder George, and the beginning of that of the younger, he returned to France, and was received into the number of the greatest courtiers. He remained there, however, only a short time, and left it in disgust with the petty intrigues which he found to form the principal occupation of the miniature court of the son of the exiled king. The next year he revisited Scotland, where he remained a considerable time, which he employed in literary labour. On visiting England, he obtained, through the influence of Dr. King, the degree of doctor of civil law in the University of Oxford. He was also admitted a member of the Royal Society of London. After his return to France he was appointed intendant to the town of Turenne, where he afterwards became Duke of Bouillon; he held this situation till the year 1741.

The writings of the Chevalier Ramsay are more remarkable for the purity of their style and the perfect knowledge which they manifest of the French language, than for their depth or originality of thought. As a theologian he was visionary in the extreme, and his orthodoxy, even according to the principles of the church he had adopted, is open to considerable doubt. His reputation as a historian is chiefly founded on a religious reputation that he did not live to publish some philosophical works which he was preparing, such as his answer to Spinosus, and a treatise on the Progress of Human Understanding, in which, says a writer of that time, he intended to divide the world into several sects that would be said to him, and to separate him from all his own in his own. (Spence's Anecdotes, p. 84.) The work which he best known, is his Voyages de Cyrus, an account of the travels of a Frenchman, but, according to Vautier, a very feeble one. The character of Zara gave considerable offence to the Princess of Conti, one of the most esteemed ladies of the age, who imagined that she was portrayed in it. There is an excellent translation of that work, by Hooke, though said to have been accomplished in the short space of twenty days [Hooke, Nathaniel, P. C.] it was at the same time mistaken for an imposture respecting his it being that Ramsay had written the Voyages of Cyrus in English as well as in French. The best edition of the French is that of Paris et Londres, 1727, 2 vol. 8vo. The work, however, for which posterity is most indebted to him is that entitled 'L'Histoire de la Vie de Francois de Salignac de la Motte Fenelon.' Hugues, 1728; published also in London the same year. His great intimacy with Fenelon has made it as visible and received many interesting facts of his private life, and it contains a valuable record of his opinions. His other published writings are 1°, 'Discours sur le Poéme Etoile,' originally forming the preface of his edication of that poem, 1727, 8vo. 2°, 'Essai de Politique,' 1730; it was afterwards reprinted under the title 'Essai de Politique.' 3°, 'Histoire de Turenne.' Paris, 1734, 3 vols. in 8vo. and 4 vols. 12mo. With some affection in the style and a redundancy of reflection this history possesses much merit from the precision of its facts and the lively portraiture of its characters. 4°, 'Le Psychométrie, ou Réflexions sur les différentes Caractères de l'Esprit,' par un Mylord Anglais.' A posthumous work published at Glasgow, 1749, 4 vol. 12mo., in English, entitled 'Philosophical Principles of Natural and Revealed Religion explained and unfolded in a Geometrical Order.'

(Dictionnaire Historique, 4 vols., Amsterdam, 1763; Dictionnaire Historique et Chronologique, Paris, 1735; Steele's Dictionaries of Books and Men, London, 1826. The details of his conversion to the Roman Church will be found in the life of Fénélon by le Père Querebeuf, appended to his edition of his works."

RAMSAY, ALLAN, an eminent portrait painter in his time, and the son of Allan Ramsay the poet, was born in 1713, in Edinburgh, the birth-place of his father also; the circumstances is alluded to by Churchill, in his satire of the "Prophecy of Famine."

'Then came the Ramsays, men of worthy note, 
Of one particular; as the other whores.

'And Ramsay,' says Edwards, 'may be called self-taught; but he studied a short time in Italy with Solimena, and F. Bernardi, called Imperialis. After practising a short time in England, he settled in London, where he was introduced by Lord Boile to George III. when Prince of Wales. He painted two portraits of the Prince, which were engraved, one by Ryland, and the other by Wollcot. At the death of Mr. Shelburne, in 1767, Ramsay succeeded to the place of painter to the king; he retained the place until his death, when he was succeeded by Sir Joshua Reynolds. He died at Dover in 1784, on his return from a visit to Rome; he had already been a pensioner at the Academy of St. Luke. He was not an excellent portrait painter, was superior to the generality of the painters of his time; he was Walpole's contemporary, and is noticed in somewhat flattering terms by that universal critic, considering with whom he is coupled: he says, 'Reynolds and Ramsay have wanted subjects, not genius.' Edwards says that Ramsay was not devoted to his art: he allowed literature to divide much of his time with it. He was married twice: his second wife was a daughter of Sir David Lindsay. His son and daughter survived him: the son became a general in the British army, the daughter was married to Sir Archibald Campbell.

(Edward's, Anecdotes of Painters; Cunningham, Lives of the British Painters, &c.)

RANDIA (nominated after Isaac Rand, M.D., once a demonstrator of botany at the Chelsea botanic gardens), a genus of plants belonging to the natural order

R. digitata, Bog-Randia, is a thorny branching small, shrub or tree, with oval leaves, rather blunt, cuneate at the base and smooth. The flowers are very sweet-scented, sessile, solitary, mostly two-celled. The calyx has about six teeth, rather smaller than the villous corolla. The fruit is smooth, yellow, resembling a small crab-apple, firm and fleshy. The seeds are oval, numerous, and lying in mucus. The fruit when bruised and thrown into water, causes a great atonement or even kills fish, having the same effect as the Coccus indica, which is not, however, known in the East Indies, where this plant grows. In the form of powder it is a powerful emetic. An infusion of the bark of the root is employed to nauseate in bowel complaints.

R. wilsoniana, Bog-Randia, has almost terminal opposite thorns, tetragonal branches, oblong leaves somewhat cuneate, glabrous; the flowers solitary, sessile, almost terminal. It is a native of the British Isles, and in this it resembles the last plant. The flowers are large, white, and fragrant, and in two or three at the top of the branches. The berry is about the size of a pullet's egg, ash-coloured or olive-grey, and 2-celled. The seeds are small, brown, pointed, and winged. The flowers of this species render it deserving of a conspicuous place in the hothouse. The uncommon appearance of this plant is also in its favour. There are 39 species of Randia, none of which, however, are applied to the true Randia. The flowers of these species render it deserving of a conspicuous place in the hothouse. The uncommon appearance of this plant is also in its favour. There are 39 species of Randia, none of which, however, are applied to the true Randia. The flowers of these species render it deserving of a conspicuous place in the hothouse.
RANGONE, a noble family of Modena, which became illustrious in the middle ages, not only for the part which it took in the political and military vicissitudes of Italy, but more particularly for the patronage which it gave to learning and to the learned. Count Nicolò Rangone, who lived in the latter part of the 13th century, was the father of eight sons and two daughters, whom he caused to be instructed with great care, and all of whom became distinguished for their love of science and literature. The learned Visdomini, who was preceptor to several of them, has left an interesting memorial of the care bestowed on their education in his Dialogues entitled 'Antoni Marie Visdomini de Ocio et Sybillis.' One of his pupils, Count Guido Rangone, figured as a distinguished gentleman in the learned service of the court of King Francis I. Filélio, in his book 'de Optima Hominum Felicitate,' which he addressed to Count Guido, enumerates the feats he had performed in his military career, and praises him likewise for the liberal encouragement which he afforded to the learned. Bernardo Tasso, father of the great poet, was for a long time secretary to Count Guido. Guido died at Venice in 1537, his brother, Cardinal Ercole Rangone, who died young during the pillage of Rome in 1527, is likewise extolled for his love of learning by Giglio Giraldì, and also by Vida in his second book 'de Arte Poetica.'

Curtius Rangone, a historian, took for his second husband Cesare Fregoso, a well-known Genoese emigrant in the service of Francis I, who was murdered in 1541 by the emissaries of the Marquis del Vasto. Governor of Modena in 1528, he was closely connected with Benedello, the celebrated novelist, who wrote many of his tales for her entertainment. Ginerva Rangone, sister of Costanza, married first a nobleman of the Correggio family, and then, in the 17th century, together with Count Brugnoni and Benedicto, the celebrated novelist, who wrote many of his tales for her entertainment. Ginerva Rangone, sister of Costanza, married first a nobleman of the Correggio family, and then, in the 17th century, together with Count Brugnoni and Benedicto, the celebrated novelist, who wrote many of his tales for her entertainment. RANULCULUS (from rana, a frog, because many of the species inhabit humid places frequented by that reptile), a genus of plants, the type of the natural order Ranunculales. It has 5 sepals, occasionally 10, with a nectariferous excurrent acorn; its ovary is hemispherical, and the axis is slightly straight, the achenia ovate, somewhat compressed, mucronate, arranged on globose or cylindrical receptacles. The species are mostly annual, and if applied when fresh to the skin will produce blisters; this quality is destroyed by drying or by heat.

A. aquatilis, Water-Crowfoot, has a floating stem and submerged leaves divided into numerous capillary segments spreading on all sides. The floating leaves are reniform, from 3- to 6-parted, the lobes wedge-shaped, toothed at the top, the petal obovate, larger than the calyx, the flowers white. It is native throughout Europe, Western Asia, North Africa, and also in America and England, in pools and stagnant waters. It is the Baradak vrifying of Dioscorides, 2, 206. Sometimes it produces very large flowers, and makes a handsome show in ponds and ditches; the curious variety in the flower, the leaves thinner and more nearly round, is greatly prized for its beauty. Dr. Pulteney contradicts the assertion of its deleterious qualities, and says that it is not merely harmless but nutritious to cattle, and tells us that on the borders of the Avon it is said to be carried 3 miles in a cart. A plant entirely new to England is the Linnæus, as used in gardens, the same species which, under the name of Scrophula elata, is used in the treatment of many diseases in Sweden. A notion that the root is efficacious in the cure of piles gives it its common English name. We usually find the flower closed from five to nine in the evening, and in wet weather. It is the χλευδον of Theophrastus, Hist. Plant, 7, 14, and the χλευδον μερυ of Dioscorides, 2, 212, and of Pliny, Hist. Nat. 258.

A.acamptus, Curly-Crowfoot, has a fibrous root, the radical leaves 3-cleft, dentate, the stem-leaves once or twice ternate, with linear lanceolate segments, the calyx exerto-petal, the carpels margined, beaked, and spinous; the flowers are pale yellow. It is more hardy than the Burdocks, and is found in England and Great Britain. It is very acrid and dangerous to cattle, though they are said to eat it greedily.

M. Broughon, who has given a particular account of its qualities, relates that three ounces of the juice killed a dog in four minutes. Several sheep were killed by eating this herb at Turin, which first led to an investigation of the matter.

A. bulbosus, like other of the genus, is extremely acrid, and raises blisters and produces extensive inflammation of the skin. Gilibert states that it vesicates with less pain than cantharides and without affecting the urinary passages.

A. aestivalis, common Garden Ranunculus, has ternate or 3-lobed leaves which are rounded and have serrate margins. The flowers are usually yellow, occasionally white, and are accompanied by a yellow sepal. The fruit is a capsule containing numerous seeds. The plant is commonly found in damp meadows, fields, and along roadsides. It is sometimes used in traditional medicine for its astringent and anti-inflammatory properties.
riternate leaves, the segments toothed or deeply trifid, the stem erect, simple, or branched at the base, the calyx spreading, afterwards reflexed, the spikes of the carpels cylindrical. It is a native of the Levant, and is referred to by Dioscorides, 2. 36. The three species in our gardens have been described, which some have regarded as species:—1. R. a. vulgaris, with the stem branched at the nodes, the leaves ternate, the segments trifid, cut, acute. The flowers of this variety are generally formed double, and have all colours except blue. It is called the Persian Ranunculus. 2. R. a. sanguineus, with a simple stem, ternate leaves, the segments similar, or the lower are cut, the upper are oval or yellow. This is called the Turkey Ranunculus. 3. R. a. tenuifolius, with a somewhat branched stem, and multilab leaves with linear acute lobes. It is a native of the island of Cyprus, and has white or yellow or purple flowers.

The Garden Ranunculus is a florist's plant, and has been cultivated with great care. The garden varieties of this species are very numerous, as no two plants produce flowers precisely alike. Maddock, who wrote on these plants, had a collection of 800 varieties, all with proper names. In judging of a Ranunculus the following qualities are desirable:—The flowers should be of a hemispherical form, at least two inches in diameter, consisting of numerous petals, gradually diminishing in size to the centre, lying over each other, so as neither to be too close nor too much separated, but having more of a perpendicular than a horizontal direction, in order to display the principal effect. The petals should have rounded edges, their colours dark, clear, rich, or brilliant, either of one colour or variously diversified on en, white, sulphur or fire-coloured ground, or else regularly striped, striped horizontally (Linn., Don.) or vertically. The cultivation of this plant prefers a rich loamy soil, which should be well manured, and it is customary when forming beds for it to place a layer of well-rotted cow-dung seven or eight inches below the surface. The roots are divided into roots, which may either be planted in November or March. The former is the best time, but the roots should then be mixed. In order to obtain varieties, seeds should be obtained from the single or semidouble plants, and planted in August. The following year, when their leaves drop off, the roots should be taken up and dried in the same manner as the old roots, and planted with them in November.

The R. lanuginosa of Linnaeus is the *bárapasِ fíus* of Dioscorides, loc. cit. The R. muricatus, Linn. is the *bráarpasِ fíros* of Dioscorides, loc. cit.

(Deo, Gardener's Dictionary; Lindley, Flora Medicea; Fras, Synopsis Flora Classica Plantarum; Burnett, Outlines of Botany.)

RAPHIOUSAIUS, *e* genus of fossil Reptiles from the lower Carboniferous strata of the British islands.

RAPE. [Rape, P. C.: LAW, CRIMINAL, P. C. S.]

RAK, RASMUS CHRISTIAN, one of the most distinguished linguists of modern times, was born on the 2nd of November, 1765, in the island of Fyen, or Funen, in the kingdom of Denmark. His parents were poor people, but the boy's talents and inclinations procured him friends who afforded him the means of procuring his education. He was first engaged with the divinity, and afterwards spent some time in Iceland, and also made journeys to Sweden, Finland, and Russia for the purpose of increasing his knowledge of languages, for which he had a very extraordinary talent. In 1808 he obtained a situation connected with the university library at Copenhagen, and he availed himself of the opportunity by making himself acquainted with the most ancient documents of northern history and literature. His great abilities in this branch of learning led him very soon to turn his attention to comparative philology, to search after the connecting links and trace them to their common origin; and in order to complete this branch of study, he undertook in 1817, with the support of the Danish government, to go to Russia, whence he proceeded in 1819 to Persia. He made some stay at Teheran, Persepolis, and Shiraz, and in 1820 went to India, from whence he returned in 1822 to his native country. In this expedition he had purchased for the Copenhagen library 113 ancient and rare oriental manuscripts, among which those in the Pali language were the most valuable. Soon after his return to Copenhagen, he was invited to the chair of languages in the university of Edinburgh, but as he declined the offer, he was appointed professor of the history of literature in the university of Copenhagen. The king had promised him his support, if Rask should make any progress in the study of the ancient languages of the northern antiquities, and he took an active part in the management and editorial of the journals of these societies. At the same time he was engaged in the preparation of an Armenian dictionary, an Italian, Low German, and Russian Grammar. In 1829 he was appointed professor of oriental languages and chief librarian of the university library. Henceforth his researches were concerning the也不错 eastern languages, but his edition of Lokman's Fables, Copenhagen, 1832, shows that his knowledge of Arabic was very deficient; and it may be said in general that, as far as the oriental languages are concerned, he had more skill in general comparisons and investigations of their grammatical structure than an exact knowledge of any particular language. His works show that there was scarcely a language worth studying of which he had not some knowledge: and all the civilized languages of Europe were almost as familiar to him as his own mother-tongue, and his knowledge of the northern languages is unrivalled. He died at Copenhagen on the 14th of November, 1832, and his numerous MSS. relating to philology were given up by his relatives to the king's library at Copenhagen.

The principal works of Rask are:—1. An Introduction to the study of the Icelandic and ancient Northern Languages, Copenhagen, 1811; 2. An Anglo-Saxon Grammar, Stockholm, 1817, one of his best works, has been translated into German and English; 3. Investigations concerning the Origin of the Indo-European Languages, the annual report (Owen.) Copenhagen, 1814; 4. An edition of Bjorn Halderson's Icelandic Dictionary, Copenhagen, 1814; 5. A Spanish Grammar, Copenhagen, 1824; 6. A Friesian Grammar, Copenhagen, 1825; 7. An attempt to introduce the six principal languages of the Dutch language to Principles, Copenhagen, 1826, is a strange work in which Rask attempted to introduce a complete reform in Danish orthography. He did not succeed in his attempt, but the work is full of the most extraordinary ideas. 8. On the age end authenticity of the Zend a Vesta, Copenhagen, 1835, was translated into German by F. von der Hagen, Berlin, 1836; 9. A small Grammar and Vocabulary of the Aera Language. In the last year of his life he finished a very complete Grammar of the Language of Lapland. A number of essays on linguistic subjects appeared in various journals, and in Vater's 'Verzeichniss' there is one on 'Die Thrakische Sprachklasse,' which is of great importance and interest. Comparative philology is greatly indebted to Rask, for he was the first who pointed out the connection between the ancient northern languages on the one hand, and of the Lithuanian, Slavonic, Greek, and Latin on the other hand. (Zeitschr. der Zeit, third Series, No. xxxvii.)

RATIO, COMPOSITION OF. To the few words which are used to express this notion in Euclid, he will be worth while to add considerable development. The idea implied in composition of ratio is very imperfectly treated in Euclid: and yet upon the correct understanding of it depends the whole of the developments which follow. In incomensurables which the fifth book gives is real or imaginary.

In every matter connected with elementary geometry, confusion may and often does arise from mixing together criticisms of two different kinds; on Euclid as a writer, and on the subject as a matter of thought. To avoid such confusion in the present instance, we shall begin with the consideration of what we may call Euclid's General Scheme of Euclid, nor Playfair's Euclid—but in Euclid of Alexandria.

There is nothing on ratio compounded (επαρθμενος) of ratios in the fifth book; the word translated composition (συστάσις) refers to such a process as the formation of the ratio of A+B to B from that of A to B. But the definitions of duplicate, triplicate, &c. ratio are laid down; which, as we shall see, are particular cases of the same notations. These definitions are as follows:—if A, B, C, D, &c., be in continued proportion, so that as A to B, B to C, C to D, &c., so on, then the ratio of A to C is called the duplicate ratio of that of A to B. The ratio of A to D is called the triplicate ratio of A to B, and so on.

In one proposition, and in one only, is the phrase composition of ratios used: in the 23rd of the sixth book, where it is said:—"Equiangular parallelograms have to one another the composition of the sides." There is no definition at least, it
It is true that there is found in a great preponderance of manuscripts a passage and its corresponding ratio. It is among the definitions of the sixth book, and literally translated is as follows:—"A ratio is said to be compounded of ratios, when the \( \frac{p}{q} \) of the ratios multiplied together make a certain [ratio]." On the word left untranslated (which, we believe, must be translated by quantitativitie), we refer to Ratio, P. C. This definition is admitted into the editions of Basle and Oxford, and into Briggs' edition of the six books. Peyrard has omitted it in the Paris edition, because, in his celebrated Vatican manuscript, it is not in the text, but has been added at the side. The Berlin editor admits it in parentheses as a disputable passage. Set a scholar to make the text of Euclid from the ordinary mode of weighing the evidence of manuscripts, and there is little doubt this definition must appear as a part of the elements. Set a geometrical reasoner to settle the question, with the idea that he must be either deceived by the rest of the book, and there is as little doubt that it would be rejected. The meaning of the passage is, apparently, that if two ratios be expressed numerically as those of \( a \) to \( b \) and \( c \) to \( d \), the ratio compounded of those ratios is to be the ratio of \( 7x6 \times 4x11 \); or possibly, that, expressing the above ratios as those of \( \frac{7}{4} \) to \( 1 \) and \( \frac{6}{1} \) to \( 1 \), the compounded ratio is that of \( \frac{c}{d} \times \frac{a}{b} \) to \( 1 \).

In the early translations from the Arabic, the definition is omitted, and reference is made in demonstrating vi. 23 to a note inserted among the definitions of the fifth book, which is very insufficient. But the phrase there is that the ratio of \( f \) to \( a \) is \( \frac{h}{g} \) from those of \( f \) to \( g \) and \( a \) to \( h \). And to the definitions of the seventh book several are added, one of which is, that in a series of numbers the ratio of the first to the last is produced from the successive ratios of each to the one following.

In many manuscripts there is a scholium preceding the sixth book, which August, the Berlin editor, though not admitting it into Euclid, thinks must be of high antiquity; in which he fully agrees with him. It is to be found in the Basle edition, and in the notes to the Berlin. This scholium, while it gives confirmation to the preceding view (which hardly wants it), takes the same side on the meaning of the word ratio as we have done. ([Ratio, P. C.] And we find that Wallis was the person who suggested to Gregory jamnepatellis instead of quantitates as the translation. See his discussion of this point at length in his English Algebra (1844), ch. 19 and 20; revised in his Latin Algebra (Works, vol. ii. ch. 19, 20), and again at p. 665 of the same volume, where there is a defence of this definition against Henry Savile, who (Propsect. in Eucl.) had considered it as a great defect. To the text of Euclid we have only further to say, that this consent of Savile, Wallis, and Gregory, as to the genuineness of the definition in question, is of great weight. But with regard to the matter of the definition we agree entire, in think that the word valueless needs definition to quite as much as the term composition of ratios itself. This definition, it will be observed, either restricts the composition to ratios which are of commensurable magnitudes, or implies an addition of two integers, and a division of the resulting fraction. An old scholiast on Euclid (cited from Daseypodius by Meibomius and Wallis) is of opinion that \( \frac{a}{b} \) is used rather than the more modern \( \frac{a}{b} \). It is possible that it may be understood in a wider sense, so as to include fractional and incommensurable ratios. That is, as Wallis ex-

presses it, how-much-fold-as need instead of how-many-fold, that much may suggest the idea of a part of a time (commensurable or not) which many would only suggest that of an integer. We cannot much admire this refinement; nor does it give any help: for the introduction of the idea of incommensurability numerically expressed, so as to be fit for arithmetical multiplication, would vitiate Euclid's whole system of proportion.

But the oldest testimony, both to the existence of the definition, and the meaning of the disputed word, is Etosticus, in his commentary on book ii. prop. 5 (of Torelli, 4 of the preceding editors). He here cites, expressly from the elements, the definition as given; and adds, as the explanation of it, that, by multiplication, turns the consequent into the antecedent. This number, be says, gives name to the ratio, and he cites Nicomachus and Heron as understanding it in the same way. But, he goes on to say, the word is more properly taken when this number is an integer.

Leaving now out of view what Euclid really did write, we shall proceed to consider the subject of composition of ratios, so as to supply what, on any supposition, must be assigned to be wanted in the elements. The notion of a ratio is easily and almost necessarily connected with the idea of alteration in that ratio. We cannot express a ratio without two magnitudes, of which, whether in the ratio given, becomes the second. If we want to alter in the ratio of \( P \) to \( Q \), this is easily done when the quantity to be altered is \( P \); for then the process is only writing \( Q \) instead of \( P \). But if it is \( Q \) that is to be altered, the quantity by the five found, so that \( A \) and \( B \) shall have the same ratio as \( P \) and \( Q \).

If it be a numerical ratio which we consider, say that of \( 3 \) to \( 6 \), alteration of any number in that ratio implies that we change all its terms by the same factor, and alter the ratio of three into the same fraction of five. Alteration of any magnitude, say \( a \) length, in that ratio implies that, choosing any length as a measure, we alter every three such lengths which the given magnitude contains into five, and every fraction of three into the same fraction of five. This amounts to changing the number or magnitude into five-thirds of what it was, and generally, alteration in the ratio of \( a \) to \( b \) (numbers) is nothing but multiplication by \( \frac{a}{b} \).

Take a magnitude \( A \), alter it in the ratio of \( P \) to \( Q \); say that then becomes \( B \), that is \( A \) to \( B \) as \( P \) to \( Q \). Take the magnitude we left off with, \( B \), alter it in the ratio of \( R \) to \( S \), making it \( C \). Take \( C \), alter it in the ratio of \( V \) to \( W \), making it \( D \). Then at three processes, by three successive alterations dictated by three ratios, we have arrived at \( D \), which must have altered \( A \) in the ratio of \( A \) to \( D \). Say that the ratio of \( A \) to \( D \) is simply expressed by that of \( M \) to \( N \). Then, if we begin with \( A \), and alter it at once in the ratio of \( M \) to \( N \), we change it into \( D \), producing the same effect as if we had successively altered in the ratios of \( P \) to \( Q \), \( R \) to \( S \), and \( V \) to \( W \).

Hence the ratio of \( M \) to \( N \) properly is said to be compounded of the ratios of \( P \) to \( Q \), \( R \) to \( S \), and \( V \) to \( W \); it dictates the alteration which will positions at once the effects of the three alterations prescribed by the three other ratios. In like manner, we say in addition, that \( 10 \) is compounded of \( 6 \) and \( 4 \); for addition of \( 10 \) is equivalent to the addition of \( 6 \) and \( 4 \). In multiplication we say that \( 24 \) is compounded of \( 6 \) and \( 4 \). And generally, the compound should be defined as that which produces the united effect of all the components, when both components and compound are used in the same way. Euclid, vi. 23, is now more than a mere addition to the phraseology of geometry. The parallelograms \( ABCD \) and \( EFGH \) [the reader may draw the figure for himself] being equiangular, it tells us, if we take any magnitude and alter it in the ratio of \( AC \) to \( EG \), and then alter the result in the ratio of \( AB \) to \( EF \), the change thus made at two steps might be made in one by altering the original magnitude in the ratio of the area \( ABCD \) to the area \( EFGH \).

This process applies equally to commensurable and incommensurable ratios; but in the former case of course the arithmetical substitute for composition of ratios is easy. We want to compound the ratios of \( a \) to \( m \) and of \( a \) to \( b \), all four

469
being integer numbers: it being known that every commensurable ratio is expressible by the ratio of two integer numbers. Take any magnitude $P$, and alter it in the ratio of $m$ to $n$: it becomes $n$-raths of $P$. After this in the ratio of $a$ to $b$: it becomes $a$-raths of $mb$-raths of $P$ which would also be obtained by altering $P$ in the ratio of $ax$ to $bxm$. Hence composition of numerical ratios is performed by multiplication of the antecedents for an antecedent, and of the consequents for a consequent. The process then is merely equivalent to that of the multiplication of fractions.

If $\frac{a}{m}$ and $\frac{b}{n}$ were called the quotants (quotantia) of the ratios, then the quotancy of the compound ratio is the product of the quotants of the components, as in the definition (be it Euclid's or no) which is found in the manuscripts of the elements.

Duplicate ratio ($\frac{a \times a}{m \times m}$) has been defined by Euclid in the manner hereinafter given. But it is in fact the ratio arising from the composition of two equal ratios. Suppose we want to compound the ratio of $P$ to $Q$ with the ratio of $P$ to $Q$. Take a magnitude to begin with, which may as well be $P$ itself: alter it in the ratio of $P$ to $Q$; it then becomes $P$. Alter $Q$ into $R$ in the ratio of $P$ to $Q$; that is, let $R$ be a third proportional to $P$ and $Q$. Then $P$ is compounded of $Q$, $R$; and our two steps, or alterations, are an addition in the ratio of $P$ to $Q$: hence Euclid's duplicate ratio is the ratio compounded of two equal ratios; and, similarly, triplicate ratio ($\frac{a \times a \times a}{m \times m \times m}$) is that compounded of three equal ratios.

The subduplicate, subtriplicate, sesquiplicate, &c. ratios, which later geometers used, completed that language of multiplication and division applied to operations of powers and roots which Euclid laid the foundation of, and suggested the idea of logarithms. [See also Addition of Ratios, P. C. C.]

The propositions requisite for the establishment of the direct use of compound ratio are contained in the fifth book. But in the inverse use there is a more involved discussion in the converse part of vi. 22. It is supplied by a lemma added at the end of the proposition; which is found in almost all the manuscripts (even in the Vatican and the manuscripts in Bryant); and Bryant admits it accordingly. This is a pretty sure sign that Euclid did not give the lemma; for he never refers to anything which is to come after what he has laid down. Robert Simson omits this lemma, and so leaves the proposition underspecified. What is wanted is the following:—It is impossible that the same ratio should be the duplicate ratio of two different ratios; or, if $A$ be to $B$ in the duplicate ratio of $A$ to $X$, and also in the duplicate ratio of $A$ to $Y$, then $X$ and $Y$ must be equal. If possible, let them be unequal; say that $X$ is the greater:

\[ A \times B \]
\[ A \times Y \]

Then because $X$ is greater than $Y$, the ratio of $A$ to $X$ is less than that of $A$ to $Y$. But the ratio of $A$ to $X$ is that of $X$ to $B$; and the ratio of $A$ to $Y$ is that of $Y$ to $B$; therefore the ratio of $X$ to $B$ is less than that of $Y$ to $B$; and therefore $Y$ is less than $X$; but it is also greater, which is absurd. Consequently $X$ and $Y$ cannot be unequal, &c. By a continuation of this process it may easily be established that a given ratio can only be the triplicate of one ratio, only the quadruplicate of one, and so on.

It is unnecessary to say anything on the decomposition of ratios. Clear as it becomes in arithmetic, after a while, that every multiplication is a division and every division a multiplication, it is much clearer from the beginning, in this subject, that every composition is a decomposition, and every decomposition a composition. Suppose that $P$ to $Q$ is the ratio of $A$ to $B$; and $C$ to $D$; we wish to return back again to the ratio of $A$ to $B$. We must compound the ratio of $P$ to $Q$ with that of $D$ to $C$; for it is easily made obvious that the ratios of $C$ to $D$ and $D$ to $C$ compounded give the ratio of a magnitude to itself, the ratio of equality, the use of which effects no alteration.

It is now easy to see that all the operations of algebra which belong from multiplication inclusive, must be represented in geometry by operations of composition, &c. Robert Simson, who, as we have seen, has left a demonstration of the sixth book absolutely unfinished, though ‘Theon or some other ancient writer’ had provided a scheme which supposed what was wanting, has thought it necessary to add some very complicated propositions on compound ratio at the end of the fifth book. If they were intended as illustrations of the great difficulty of rendering the commonest propositions of algebra into geometrical language (and what else could have been meant it is hard to imagine) the algebraical equivalents should have been introduced. Take the proposition $K$, for instance, which it may safely be asserted no beginner ever fathomed. The following is an arithmetical case of it.

If \[ \frac{a}{c} + \frac{e}{d} \]
\[ \frac{b}{d} \]
\[ \frac{f}{a} \times \frac{k}{m} \]

And \[ \frac{a}{c} \]
\[ \frac{b}{d} \]
\[ \frac{f}{a} \]

Then \[ \frac{e}{d} \]
\[ \frac{k}{m} \]

REAMURICACEAE, a natural order of plants belonging to the Exogenous class. It has a 5-parted calyx, surrounded externally by imbricated bracts; 5 petals, hypogynous, unequal-sided, sometimes having a pair of membranous plates planted upon their middle; definite or indefinite hypogynous, monadelphous, or polyadelphous stamens, with or without a hypogynous disk; the anthers ovate, turned inwards, and bursting longitudinally; 2-4-5 carpels, partially separate from each other, surrounding a central placenta which passes into the base of each; or 2 or 4 ascending antapetalous ovules, with filiform or sulcate styles; a capsule fruit with 2 to 8 valves and as many seeds as it is. It is diminished by abortion; shaggy definite erect seeds, with a straight embryo surrounded by a small quantity of nearly albumen, and the radicle next the hilum. The species of this order are small shrubs, with compound leaves alternately, and have no stipules, and are overgrown by resinous suck girdles.

This little order consists of three genera, Reamuria, Holoschua, and Eichwaldia, which were formerly united under the name of Tamariscceae; they have, however, but little affinity with that order. Their true affinities seem to be with Hypericaceae near to which Lindley has placed them. The species are generally natives of the coast of north Africa, and of salt plains in the milder parts of northern Asia.

The genus Reamuria was named by Hassequist in honour of René Jean Baptiste Reamur. [Reaumur, P. C. C.]

It has a 6-parted involucrated calyx; 5 petals, persistent, furnished at the base on each side with a ciliate appendage; numerous pentadelphous stamens; 5-6 stigmas; a 5-valved 5-celled capsule, with valves easily separating from the septa, and shaggy seeds.

R. verniculata has subulate semiterete imbricated leaves, crowded on the branches. It is a native of Sicily, Bormla, and Egypt. This plant resembles Salsola fruticosa. It is used at Alexandria as a remedy for the itch, being bruised and applied externally, and a decoction taken internally.

R. hypericoides has lanceolate flat rather remote leaves. It is a native of Algeria and Persia; these plants are elegant little shrubs of easy culture, which thrive well in a mixture of sandy loam and peat; and young cuttings will grow freely in sand under a glass-house.

Holoschua, or "black thistle," and $\frac{a \times a \times a}{m \times m \times m}$, "wool," or "thick hair") has a 4-6 parted calyx; 4-5 petals; 8-10 hypogynous monadelphous stamens inserted into an hypogynous gland; 2-4 short sulcate styles; the capsule 3-4 angled, 2-4 valved, 2-4 celled; the seeds few, large, surface shaggy. The only species is H. Songarinia, found by Ehrenberg in the Soongarian desert of Siberia. In cultivation this plant requires to be watered with salt water. All the plants of this order abound in saline matter in their tissues.

(Lindley, Vegetable Kingdom; Don, Gardener's Dictionary; Lindley, Flora Medic.)

REBE is the old English word for Discount [P. C. C.]. The discounting of a sum of money, or the paying something less for it before it becomes due, is now always done by striking off a certain per centage from the sum. Thus, if a sum be due a year hence, say 100L, discounting at five per cent. means paying 95L now in lieu of 100L a year hence. There are one or two old difficulties connected with discount, which we intended, as we thought, to notice under borrowings. The first is that of the equation of payments. Were it not for the difficulty, and its principle, this would not be worth notice. It was at one time the custom of the works on arithmetic to adopt propositions which supposed some of the numbers due at different times, at what time the total amount is to be paid at once, in such manner that the receiver may gain, by the sums which are prepaid, what he loses by those which are overdued.
To take a simple case, say it is understood that money makes five per cent. simple interest, that 100l. is due in three years, and 300l. more in seven years. The first rule that was given looks, as the reader knows, to the payment of the whole 400l. in six years; by which the interest on 300l. paid a year before its time balances on 100l. paid three years after its time. But this, it is said, was not fair; for not interest, but discount, should be allowed for the sum paid before it is due. That is, the 400l. paid at the intermediate time should yield 100l. due + interest on it since it was due + a sum which put out interest up to the 300l. at the end of the seven years. The rule for this case gives a result 5-9615574 years, instead of six years; which will be found to satisfy the conditions.

In truth, however, it depends entirely upon what the notion of fairness is, whether one rule is better than the other, or whether either will do. And it must be remembered that simple interest is a fiction in real business. A creditor cannot demand more than simple interest by law; but it does not therefore follow that because certain money is paid under the name of interest, the receiver will let it lie barren in a bag. But what we say is this: keep to the fiction on which both rules are constructed, let all interest-money remain barren, and the two rules will come to the same thing in the end. And it is not fair to construct rules on the supposition of simple interest, and then to complain of the inaptitude of these rules to represent the results of real business. Remaining by simple interest, let us see how the receiver will stand at the end of the seven years, upon the different suppositions.

1. If no equation of payments be made, he will have 100l. + four years' interest + 300l. just received, 420l. in all, with which he is to go on making interest on 400l. only.

2. If he receive by the first rule 400l. at the end of six years, he will at the end of the seventh year have 420l., of which 400l. is to go on at interest as before.

3. If he receive by the second rule he will have at the end of the seventh year (100l. + £261... years' interest) which he received + 1036... years' interest which he makes on the 300l. (the other part not making interest) + the sum which will in 1-036... years yield 300l. (285-19...%.) + the interest on this. That is, 420l. altogether, of which 200l. is interest only; for the last-mentioned item, though gained in the manner of interest, is discount intended to make up a principal. Or, if any one will not admit this last distinction, then the most approved rule puts the receiver in a worse position than the old rule.

The fact is, that if equation of payments were ever made, it ought to be supposed that all money, principal and interest, becomes productive money to the receiver from the moment it is received: or compound interest should be supposed. This puts the parties into a state of equity at all times, both during the longest term of debt and after. To show this suppose that A is due at the end of a year and B at the end of 8 years, interest being r per pound. To satisfy this debt by a sum A + B paid at x years from this time, the equation to determine x is

\[ A + B = A(1+r)^x + B \left(\frac{1}{1+r}\right)^x \]

and the receiver of the above sum, in years after its receipt, or x + m years from the present time, will have \( (A+B) \)

\[(1+r)^x \]

which is

\[ A(1+r)^x + B \]

Or

\[ A(1+r)^{x+m} + B(1+r)^{x+m} \]

And this is precisely what he would have had from the payments themselves. And the accumulations or present value of the equated sum are at all times equal to the accumulations or present values of the payments.

There is another remarkable case of the same kind, in which discount at simple interest is compared with notions derived from compound interest, and a rule is consequentlie said to be false which is, upon its given hypothesis, perfectly true. The value of an interminable annuity, calculated at simple interest, comes out infinitely great; or no sum is large enough to pay t. Now it is clear that 50l. will pay an annuity of 1l. a year at five per cent. for ever. And this may be called simple interest, for at the end of a year the interest of the 20l. is paid away, and the original principal only remains: so that there is no interest upon interest. But the truth is, that in the construction of all rules at simple interest, the money is arbitrarily divided into two parts, productive and unproductive, and a rule which expressly requires payment to be made from time to time out of the productive part, may produce very different results from another in which the unproductive part is paid away first. Now take the case of an annuity for three years, of 1l. money making r per pound. The ordinary rule gives

\[ \left(1+r\right)^{-1} + \left(1+2r\right)^{-1} + \left(1+3r\right)^{-1} \]

At the end of a year, this becomes

\[ 1 + \frac{1}{1+r} + \frac{1}{1+2r} + \frac{1}{1+3r} \]

The first term is partly principal, partly interest: and the remainder of annuity has become due. But the manner in which the rule was framed does not allow us to pay away the \( r(1+2r)^{-1} \) and \( r(1+3r)^{-1} \), which are never to make interest again, in part of the first year's annuity, but requires that the 1l. part of which will make interest, should all be paid so. And, when the productive money is broken in upon before the unproductive is all gone, it is perfectly true that no sum is large enough to pay a perpetual annuity: and, if this be done, not only may the rule for a perpetual annuity be objected to, but with as much justice that for a finite term of years. For instance, at 10 per cent., an annuity of 1l. for five years is worth, according to the usual simple-interest suppositions, 3-79079l. A year's interest is 38956/111.; let this all be paid away, and the balance of 1l. made up out of the principal, and so on, and it will be found that there is a sum in hand at the end of the ten years: in fact 3-79079l. will in this way be enough to meet all demands. But the manner in which the rule is constructed supposes the annual demands to be made up out of principal and interest in the following way, the sums before the lines showing how the pound yearly accruing due is raised, partly out of principal, partly out of interest:—

<table>
<thead>
<tr>
<th>Principal</th>
<th>Interest</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pay 90009</td>
<td>+ 09001 = 1</td>
</tr>
<tr>
<td>2-9932</td>
<td>09835</td>
</tr>
<tr>
<td>Pay -38333</td>
<td>-16667 = 2</td>
</tr>
<tr>
<td>2-14019</td>
<td>-43003</td>
</tr>
<tr>
<td>Pay -76923</td>
<td>+ 23077 = 2</td>
</tr>
<tr>
<td>1-38096</td>
<td>-41428</td>
</tr>
<tr>
<td>Pay -71492</td>
<td>-28571 = 2</td>
</tr>
<tr>
<td>2-6667</td>
<td>2667</td>
</tr>
<tr>
<td>Pay -66667</td>
<td>+ 33333 = 2</td>
</tr>
<tr>
<td>+0000</td>
<td>-00001</td>
</tr>
</tbody>
</table>

While if interest were made to go as far as it could, we should have

<table>
<thead>
<tr>
<th>Principal</th>
<th>Interest</th>
</tr>
</thead>
<tbody>
<tr>
<td>3-89261</td>
<td>-8926</td>
</tr>
<tr>
<td>3-26160 after paying £1.</td>
<td>26160</td>
</tr>
<tr>
<td>2-6106</td>
<td>do. do.</td>
</tr>
<tr>
<td>-90101</td>
<td>-90101</td>
</tr>
<tr>
<td>1-87107</td>
<td>do. do.</td>
</tr>
<tr>
<td>1711</td>
<td>1711</td>
</tr>
<tr>
<td>-10582</td>
<td>do. do.</td>
</tr>
<tr>
<td>-16400</td>
<td>do. do.</td>
</tr>
</tbody>
</table>

So that there would remain 164l.

The truth is, that the rule for annuities by discounting at simple interest is wrong except upon the condition that principal and interest are to be rated in a specified way (which those who understand the formula will easily collect) to meet the accruing demands. And moreover, when interest is to be all disposed of first, before any principal is touched, the rules for simple and compound interest are identical.

RECEPTACULITES, a genus of fossils proposed by Dranacre, synonymous with Eudioxidus of Murcichon.

REG

RECORD. [Readings, P. C.]

# Refining is a process applied to various processes in the useful arts, and especially in metallurgy, whereby the substances acted upon are purified by the chemical separation of dross and impurities, and of such foreign matters as may be in communication with them. The refining of metals generally is treated of under Amelioration, P. C., p. 495; and further particulars respecting the refining of the more important metals are given under Copper, P. C., p. 602; Iron, P. C., p. 54; Lead, P. C., p. 31; and Tin, P. C., p. 472. Some writers apply the name of refining to the preparation of cast-steel, noticed under Steaks, P. C., p. 3; a process which is certainly analogous, in many respects, to the preparation of metals generally. This term is applied to the purification of sugar, of which process an account is given under Sugar, P. C., p. 231.

REFLECTION. [Light, P. C.; Optics, P. C.]

REFRACTION, DOUBLE [Polarization of Light, P. C.]

REFUGE, HARBOURS OF. In the year 1840 a Commission was appointed 'to visit the coast between the mouth of the Thames and Selsey Bill; to examine the ports with reference to their being available as places of shelter for vessels passing through the Channel in cases of distress from weather, and also places of refuge for merchant vessels from enemies' cruisers in time of war, and more especially as to their being made stations for armed steamers employed for the protection of our trade in the narrow parts of the Channel.' This was a Report, but no measures appear to have been taken in consequence.

A Select Committee of the House of Commons on Shipwrecks, in a Report presented in 1848, recommended the formation of refuges in the British Channel, at the same time stating that they refrained from pointing out any particular situations for such harbours, from a conviction that such situations would be best decided on a body of scientific and experienced officers whose recommendations should be specially and exclusively directed to the subject.

On the 2nd of April, 1844, the Lords of the Treasury, on the suggestion of Sir Robert Peel, then First Lord of the Treasury, appointed a commission of ten persons, comprising ex-service and military officers and civil engineers to inquire into the most eligible situations for a Harbour or Harbour of Refuge in the Channel.

The Report of the Commissioners is dated August 7, 1844, and was presented to the House of Commons pursuant to an address dated March 6, 1845. The Treasury Minute under which the Commissioners acted assigned three principal objects of investigation:—1. The selection or formation of Harbour of Refuge for the safety and convenience of vessels navigating the Channel; 2. That, in times of war, such harbours might become stations for ships of war; 3. The extent of cost of construction and maintenance; and the advantages likely to result from such works. The Commissioners express their unanimous conviction that additional means are required to the coast of England as absolutely necessary. The harbours between Portsmouth and the Thames are only tidal harbours, and none of them is at present accessible to large steamers. The Report recommends certain ports and positions as Harbours of Refuge and Roadsteads, and certain breakwaters and military defences in connexion with them, so as not only to afford shelter to merchant ships, but by means of which, with the advantages of steam by sea, and railroads and telegraphic communication by land, the naval and military force of the country may be thrown on any point of the south-eastern coast in a few hours.

The following harbours and positions were especially examined:—Plymouth, near the North Arm; Ramsgate, the Brake, or Small Downs; Dover; Dungeness; Beachy Head, Eastbourne, and Seaford; Newhaven; Portland and Weymouth; Harwich Harbour. Of these places four are selected, viz.:—Seaford, Portland, Ramsgate, and Dover, which the Commissioners estimate the expense required for the construction of the works which they recommend as follows:—Dover, 2,500,000l.; Seaford, 1,250,000l.; Portland, 500,000l.; Ramsgate, 125,000l. The Thames is a large part of the island facing the bay is crown property, and contains abundance of stone: the holding-ground is exceedingly good, and the island has abundance of water for the supply of ships. This would afford great naval advantages for defence, and for the formation of a naval and military depot during war to any extent that may be required. Harwich Harbour, formed by the junction of the rivers Stour and Orford, is situated 30 miles from the holding-ground over an extent capable of containing many hundred ships. By the construction of a breakwater and dredging to get rid of certain shoals, the Commissioners consider that it might be converted into one of the finest and most useful harbours in the kingdom.

The military members of the Commission recommend that casemated batteries be constructed on the breakwater themselves, supported by defences on the shore flanking the approaches to the breakwaters and harbours.

At the end of the Report, W. Symonds, Surveyor of the Navy, says, 'I dissent from this Report, because I consider the mass of evidence to be in favour of Dungeness, and because I cannot recommend a large close harbour at Dover, where the pilots consider the holding-ground generally indifferent, and say that they never go to sea without their bowls of wool. As to Dungeness, the Commissioners say that it is remarkable for its good holding-ground, and that 300 sail have been well sheltered in the East Bay at one time, and that more than 100 vessels were at anchor in the same bay when the Frenchflt on Channel arrival there. As however it has not the advantage of an inner harbour like Dover, Seaford, and Portland, the commissioners do not recommend any breakwater to be constructed, but to be used as a roadstead for merchant-ships and ships of war. The holding-ground in Dover Bay was tested by Captain Washington in the steam- vessel Blazer of 500 tons burthen and 180 horses. In other words, the Commission recommended that the two breaks and the long shipping will afford a safe anchorage, and the probability of siltage, samples of the water, taken up at different times of tide and different depths, were examined by Mr. Phillips, of the Museum of Economic Geology, as to the quantity of matter held in suspension. The impurity of the sea-water, as compared with the water of the Thames taken up at Brentford, Hammersmith, and Chelsea, was, taking the mean of the experiments on each side, as 16 to 6. The Commissioners recommend further experiments as to the probability of siltage in Dover Bay before anything is determined on.

The Commission of 1840 recommended three places as suitable for Harbours of Refuge—Dover, as first in importance; Beachy Head, second; and Ramsgate, third. (Report of the Commissioners upon the Subject of Harbours of Refuge, 1845.)

REGISTRATION OF BIRTHS, DEATHS, AND MARRIAGES. Parish registers were not kept in England till after the dissolution of the monasteries. The 12th article of the injunctions issued by Cromwell, Henry the Eighth's secretary, in 1538, directs that every clergyman shall, for every church, keep a book wherein he shall register weekly every marriage, christening, and death, any neglect being made penal. In the first year of the reign of Edward VI. (1547) ecclesiastical visitors were sent through the different dioceses in order to enforce various injunctions, and, among other things, that of Cromwell with respect to parish registers. In the beginning of Elizabeth's reign this injunction was repeated, when the clergy were required to make a protestation in which, among other things, they promised to keep the register-book in a proper and regular manner. In 1884 an Act (6 & 7 Wm. III. c. 6) for a general registration of marriages, births, and deaths, was passed, and the first registration took place in the year 1885. In 1888, however, a supplementary Act was passed (9 Wm. IIII. c. 92), entitled 'An Act for preventing frauds and abuses in the charging, collecting, and keeping of the taxes imposed in the several counties, districts, and boroughs, and widows.' The 52 Geo. IIII. c. 146 (28 July, 1819) entitled 'An Act for the better regulating and preserving parish and other registers of births, baptisms, marriages, and
England.' The Annual where each Ministers, Registrars The Name Penalty established Accidental having the two schedules nexed minister, and by persons married, and by two witnesses (31). Certified copies of registers of births and deaths to be sent quarterly, when the registrar-general, under the provisions of the Superintendent-Registrar Act are extended to the Marriage Act. The general registrar-general, under the provisions of the Act are the following:—A general registrar-office is to be provided in London and Westminster (§ 2). Lord Treasurer and Lords Commissioners of his Majesty's Treasury to appoint officers, and certify to the registrar-general that the superintendent-registrar is established, having the powers of supervising the registration of the births and deaths of each district, and certifying to the registrar-general, on payment of the fees prescribed (§ 33). Indexes are to be made at the superintendent-registrar's office, searches allowed, and certified copies given to the officers of the registrar-office, searches allowed, and certified copies given (§ 37). Certified copies given at general registrar-office to be sealed, and shall then be evidence without further proof (§ 38). Ministers, &c., may ask parties married the particulars required to be registered; and wilfully giving false information is perjury (§§ 40 and 41). Penalty for not duly registering births, deaths, and marriages, or for losing or injuring the registers, not exceeding 50l. Penalty for destroying or falsifying register-books, or entries therein, or giving false certificates, is felony (§ 43). Accidental errors may be corrected, within one month, in the presence of the registrar-general, or the next superintendent-registrar, or the registrar-general, and the errors shall be corrected within the time prescribed (§§ 45 and 46). Registers of baptism and burials may be kept hereafter (§ 49). Registrar-general to furnish notices to guardians of unions, &c., specifying acts required, to be returned to the registrar-general, and which are to be published in conspicuous places of the unions or parishes (§ 90).

Another act was passed (1 Vict. c. 29—June 30, 1837), entitled 'An Act to explain and amend two Acts passed in the last session of Parliament, for Marriages, and for registering Births, Deaths, and Marriages, in England.' This act contains chiefly of arrangements necessary to extend and improve the provisions of the Registration Act.

Previous to the Registration Act coming into operation it was necessary to divide the country into districts of convenient size for equalizing the labours of the registrars by contracting the area where the population was dense and extending it where the population was thin. The Registrar-general issued a circular letter in September 1886, to the boards of guardians throughout the country, on whom devolved the duty of forming each poor-law union into registration districts, and as the unions differed much from each other in population, ranging from 3000 to 50,000, the Registrar-general left the arrangement of the unions to the guardians, subjecting them to certain principles for their guidance. Parishes and townships not under the Poor-law Commissioners were formed into temporary districts, or, where more convenient, were annexed to a district already constituted by the registrar-general. In each district a registrar of births and deaths is appointed, and also a registrar of marriages; and in each union there is a superintendent-registrar. The registrar of births and deaths is appointed by the guardian, and is paid by the union, which is divided in the district in which he acts. The registrar of marriages is appointed by the superintendent-registrar, subject to the approval of the guardians.

The total number of births and deaths of births at the end of September, 1888, was 2193, of whom 1021 were officers in poor-law unions. At the end of December 1888, the number of superintendents-registrar was 615, of whom 64 were superintendent-registars of temporary districts; at the same period the number of registrars of births was 817, of whom 419 were also registrars of births and deaths. In the first year, under the new Act, there were registered in England and Wales—

<td>1,118,814</td>
</tr>
</tbody>
</table>

Mr. Finlayson, in an estimate of the number of births, deaths, and marriages, which might require to be registered, the first year, calculated the number of births to be 8,000,565; of deaths at 335,968; and of marriages at 114,947. The approximation as to deaths is remarkable, and not less so the deficiency in the births and in some degree in the marriages. The impression is partly from the opposition of interested persons, partly from the erroneous notions of the ignorant, and partly from...
The register-general, in his 6th Report, dated August 10, 1844, states, that four inspectors had been appointed to visit every district into which England has been divided, in order to exist in the mode in which the registers perform their duties. These inspectors, among other important directions given to them, are required to see that the places of birth or death are accurately recorded; that the ages and professions of those who die are duly registered; that exactions are used to impress upon persons giving information of death the importance of producing a certificate of cause of death, in the hand-writing of the medical man who attended the deceased in their last illness.

By the end of 1830 about 350 new register-offices had been built, and the use of temporary offices had been sanctioned in many places. The ordnance-office supplied Iron boxes for holding the register-books of each district. By the end of September, 1838, register-books of births and deaths, and forms for certified copies thereof, had been provided by the registrar-general for 2198 registers of births and deaths; and marriage register-books, and forms for certified copies, had been supplied to 11,094 clergymen of the established church, to 817 registers of marriages, to 90 registering offices of the Society of Friends, and to 36 secretaries of Jewish synagogues. They are each required to transmit certified copies on paper having a peculiar water-mark as a safeguard against the substitution of false entries, every three months, to the superintendent-registrar of the district, who transmits, once a quarter, the general certificate of all the births, deaths, and marriages, which have occurred within the district during the preceding three months. These certified copies, having been deposited in the register-office in London, are there examined and arranged, and alphabetical indexes are then formed, and abstracts of them are compiled. In a few years millions of entries will have been made, and yet, for legal or other purposes, it will be as easy to find out the name of any individual from among so great a number as it is to find out a word in a dictionary or a cyclopaedia.

The registration for 1839 was—

| Births | 480,540 |
| Deaths | 391,007 |

The improvement in the registration of births, as compared with that for 1838, is sufficiently obvious.

The registrations for 1839-40 and 1840-41 are as follows:—

<table>
<thead>
<tr>
<th>Year</th>
<th>Births</th>
<th>Deaths</th>
</tr>
</thead>
<tbody>
<tr>
<td>1839-40</td>
<td>501,589</td>
<td>350,101</td>
</tr>
<tr>
<td>1840-41</td>
<td>504,543</td>
<td>355,622</td>
</tr>
</tbody>
</table>

The number of births not registered still amounts to some thousands annually, and the registrar-general is of opinion that the registration of births will not be complete until it is ascertained by the father or mother, or some other qualified informant, shall give notice within a fixed period, of a birth having taken place.

In 1841 and 1842 the number of marriages celebrated according to the rites of the Established Church were—

<table>

<td>2232</td>
</tr>
<tr>
<td>1840-41</td>
<td>5816</td>
<td>2086</td>
</tr>
</tbody>
</table>

The proportion of marriages at registered places of worship and at the registrar's offices has slowly increased, and in 1842 the number of marriages so performed represented a population of 1,160,000. The number of marriages registered in England and Wales for the solemnization of marriages was 2282 on the 30th of June, 1844. They belonged to the following denominations:

<table>
<thead>

REGISTRATION. (Scotland.)

The registration of documents in Scotland is a great and important system intimately connected with the established and connected churches, and with the execution of the law. It is thus divided into two distinct departments, which may be considered separately—Registration for Preservation, and Registration for Execution.

Registration for Preservation, in its simplest form, is merely the preserving of an attested transcript of any deed in a public register, that thus an authentic copy may be had recourse to in case the original should be lost. Besides the regular statutory records of particular deeds, there are books attached to the several courts of civil jurisdiction, in which parties may for their own convenience register such documents as do not require by any special obligatory law to be recorded. It is a general rule that extracts from any such records may stand in the place of the originals when these are not forthcoming, but that a party is not to found an extract if he have the original deed in his possession and can produce it. In the case of sales, however, and other deeds, of which, as will be seen below, it is not the deed itself, but its registration, that makes the complete title, an extract from the register is the proper document to be produced. There is a certain class of actions, however, to which it is necessary that the registration should be producible if it be accessible. These are called Actions of Reduction-Improbation. Such an action is raised against the party favoured by the deed, by some other party, and its object is to annul the conveyance, or, in other words, to declare the whole transaction invalid in law, in matter of form, in commencing such an action, the pursuer states, along with whatever other grounds of objection he may have, that the deed is forged, and he desires the original to be produced, that it may be judicially examined. The rule for production of the original is subject to modifications, where the ground of the action is extrinsic of anything peculiar to the original document; and if the original be lost without being intentionally destroyed, the inquiry must proceed on the extract and the other circumstances that can be adduced. It is usual to speak of registration for preservation, as being also for publication; and in this sense, when a conveyance of such a character that to make it effectual in the grantee's favour it must have been delivered to him by the grantor, such registration is in the general case equivalent to the delivery. It will operate in this respect in adjusting questions of competing right, as where a father makes over to one child the property that, in case of his dying intestate, would go to another, and registers the deed. It is questioned however if the mere registration of such deeds in all cases that complete the transfer of property which is necessary to bar the claims of creditors under the statutes against alienations to their prejudice by insolvents. The registration of ordinary documents for preservation has been authorized by the Act of 1834; but it is generally extends to registration in any authentic public register that is competent. Besides the central register attached to the supreme court, there are others connected with the Sheriff...
and Corporation Courts; but it does not appear to be distinctly settled what may be, with reference to various descriptions of documents in each case, a 'competent' person. By far the most remarkable of the registers for preservation is that of the Saines and Reversions, the former word expressing the Act by which an estate is created or transferred in the latter it is recorded during the life of the person entitled to the extinction of a burden, i.e. of the devolution of a temporary estate on the person entitled to the remainder. This system has been gradually formed. In its present state its unobjectionable principles as regards the subsequent ownership on the register, no latent title derived from the same authority can compete with it, and that registered titles rank according to their priority; so that if A first sets this property to B and subsequently sells the same property to C, if C get this title first recorded it cannot be questioned by B, who has only his pecuniary recourse against A. In pursuance of this system, in transactions regarding land, the public records are relied on as affording the means of ascertaining the character and title, and after they have searched for the period of prescription, or examined over a period of forty years (Tassies, P. C. S.), parties can trust that there are no latent rights, and may safely deal with the person who professed to dispose of any right connected with it. The origin of this system may be traced to the commencement of the sixteenth century, when the notaries were required to record their proceedings in their protocols, and the other officers connected with the feudal transferance of land were bound to return their edicts to the notaries. In effect a system was made to produce regularity in these registers, by penalties. It was by the Act 1617, c. 16, that the system was founded on its right principle. The preamble of that statute bears considering the great bust sustained by His Majesty's lieges by the fraudulent dealing of parties who having annulled [alienated] their lands, and received great sums of money therefore, yet by their unjust concealing of some private right found in the land, the persons entitled to the land are prevented from great sums of money altogether unprofitable; which cannot be avoided unless the said private rights be made public and patent to her Majesty's lieges. The Act then appoints the amities, reversions, &c. to be registered within three score days after execution, otherwise they are to make no faith in judgment, by way of action or exception, in prejudice of a third party, who hath acquired a perfect and lawful right to the said lands and heritages: But prejudice always to them to use the said writs against the party maker thereof, his heirs, and successors. By the other clauses of the Act the superintendence of the system is given to the Clerk-Register, and the country is divided into Registration Districts. There is one defective provision in this Act, which is still in force. Parties are allowed to register their titles either in the register at Edinburgh, or the register at Edinburgh. It is usual to adopt the latter alternative, and when it is followed, it is generally for the purpose of concealing instead of publishing the transaction. There was a case (in prefixed to the register of leases andFreehold, c. 13, which gave the registered titles priority not according to the date of their execution, but to that of their registration. To prevent injustice by the accumulation of unregistered deeds at the office, a minute-book was, by a con-
temporary Act, appointed to be kept, in which the keeper enters an outline of each document as it is presented to him. By the present practice, when a minute-book or other writing belonging to this register is presented to the keeper, he marks in the margin of the page the title of the party to which it relates. This is indorsed on the deed itself, and marks the date of registration. When the deed is engrossed at length in the register, a certificate to that effect is endorsed on the deed, mentioning the name of the Keeper and the date when the deed is then returned. Registration volumes, with minute-
books accompanying them, are from time to time issued from the General Register-office to the district registrars, so systems of the documents may be kept in parallel without being tampered with without either interpolation or mutilation being easily perceptible. When a volume is finished, it is returned with the corresponding minute-book to the General Register-office, and is then bound, with the book for reference. The real titles of all the heritable property in Scotland are thus preserved in a seriæ and indexed collection, in the General Register-house at Edinburgh. When property is offered for sale or mortgage, a search of this register is made, and the title is then referred to the parties treating for it. This is a certificate by the proper officer, describing all registered documents regarding that particular piece of land which have been recorded. The documents which are to be registered have lately been much simplified and abbreviated by the register the performance of the real title which may be registered within the sixty days of the presentation. It appears that the title is not necessary to set a title; and if the receiver of a conveyance have an absolute reliance on the integrity of the grantor and all the parties from whom that person may have derived his title, he may defer completing the conveyance, and may encounter the risk of some other person obtaining a title and getting on the register before him. The simplification of the documents to be registered tends to lessen the temptation to delay their completion and registration. It is remarkable that the enlightened mind of Cromwell appears to have comprehended the utility of this system, and that he made an effort to introduce it into England. We are told by Ludlow (Memoirs, i. p. 430). In the meantime the reformation of the law went on slowly, it being the interest of the lawyers to preserve the lives, liberties, and estates of the whole nation in their own hands, so that upon the death of any of these lands each county, for want of which within a certain time fixed after the sales, such sales shall be void, and being so registered that land should not be subject to any incumbrance, thereby this word incumbrance is altogether unprofitable in effect; it took up three months' time before it could be ascertainment by the committee.' Registration for Execution is another peculiarity of the law of Scotland, although the system of warrants to confess judgment in England in some measure resembles it. The party to a solemn deed incorporates with it a clause of registration, by which, on the deed being registered in the books of a county court, the party competent to the deed may apply to the court, that the court shall be held as pronounced in terms of the deed, and execution may proceed against the party on an extract, as if it were the decree of a court. The engagement on which such execution may issue must be very distinctly stated. Thus, if it be for payment of money, it must be for a sum named in the deed, and not for the balance which may be due on an account arising out of the transactions to which the deed refers. This method of execution was by statute (1019, c. 20) applicable to bills and promissory notes without their containing any clause of registration. To entitle it to this privilege, the bill or note must be apparently without flaw, must bear the signature of due protest, and must bear evidence that it has been protested. The operation of this system was much widened by the Act 1 & 2 k. c. 114, which extended regis-
tration for execution. The Sheriff of the Shire, and the Register of the Sheriff. REGISTRY OF SHIPS. [Shire, P. C. J.]

REGNARD, JEAN FRANCOIS, was born at Paris, according to most accounts, in 1647, though in a short biography prefixed to a collection of his works (Paris, 1819 4 vols. 18s.), he is said to have been born in 1565. An only son and heir to considerable wealth, he received an education qualified to fit him for the position in life he was likely to occupy. The death of his father soon after he had completed his studies enabled him to gratify his desire for travelling. The first country that he visited was Italy, where he spent the year 1676, a date which, connected with other circum-
stances, renders it probable that 1656 was the real year of his birth. He revisited Italy a second time in 1678, on which occasion he formed an intimacy with the Eloise, whose memory he has consecrated in his pleasing little novel entitled 'La Provençale, a Provençal love-suit, in which the lady and her husband were induced by him to visit France, and for that purpose they sailed from Civita Vecchia in an English vessel bound for Toulon. On the voyage, however, the ship was taken by the Algerines, and Regnard and his companions were taken captives to Algiers. The adventures of their captivity form the basis of the novel above mentioned, and they are sufficiently interesting and romantic in the well manner of Regnard's style. The only talent of Regnard which became serviceable to him on that occasion, was one which his love for good fare had excited, and his wealth had enabled him to gratify, the skill-
ful preparation of the noblest dishes, according to the latest principles of Parisian cookery. His culinary abilities secured for him the good will of his master and the favour of the
of his household. During his captivity he was taken to Constantinople, where he remained two years. On his return to Algiers he was ransomed for a considerable sum by the French consul; a ransom which came most opportunely, as he was about to suffer the last penalty for an intrigue in which he had been detected. He took with him to France the chain he had worn as a captive, which he carefully preserved. However, he was not observed by his unlucky adventures, and, on the 26th of April, 1681, he set out from Paris on a journey over the north of Europe. On arriving at Stockholm, he was induced by the King of Sweden to visit Lapland. He continued his journey by way of Tornea, ascended the river of that name, and reached the borders of the Finnish Ocean. On one of the rocks of the mountain of Mietwars, the limit of his excursion, he engraved the following Latin verses:

Qulla non pennis; victis non Aenea; Graecum
Haustatum, Hispanique causas Iustissimam eram,
non caput vertendarum, sed gaudium
His tandem statim suscuerat ob festit erit.

(Anno 1681, die 22 Augusti.)

On his return from Lapland he made a short sojourn at the Court of Sweden, and, after having travelled over Poland, Hungary, and Germany, came to Paris on the 4th of December, 1685, where, satisfied with the wandering life he had led, he determined upon settling. Having purchased some land which lay in a wood near Tours, where he devoted part of his time to literary pursuits, but spent the greater part of it in the society of his friends, and in the enjoyment of the capital; the summer he was in the habit of passing on an estate purchased near Paris called 'Mariage de la folie.' His devotion to gaiety and pleasure, as it was the means of lessening his utility and reputation as a writer, was the cause of his untimely death, which occurred on the 5th of September, 1710.

As a dramatic writer, the reputation of Regnard stands deservedly high; in comedy he is generally considered second only to Moléire; and Voltaire has remarked that 'no one can appreciate that great dramatist who feels no pleasure in reading Regnard.' His finest and most perfect productions are the comedies of 'Le Joueur,' written in 1696; 'some scenes in it, more especially the thirteenth scene of the fourth act, are equal to anything written by Moléire. Himself a gambler, he has given a dark but faithful colouring to the portraiture of a vice which had embittered his life, and he has transmuted his own experience upon the subject into the language of the most beautiful and energetic poetry. His next best piece is 'Le Sépulcre Universel,' in five acts, in which the humour and the versification are alike deserving of admiration. (P. C. vol. 2.)

Regnard probably possesses similar merit to the two which we have mentioned, he would have relieved French literature of the reproach which has often been felt of having no worthy successors to Moléire. The fault into which he has fallen is, that, like Piron, Greissel, and Marivaux, he has rather delineated an exaggerated representation of some particular vice or folly, that incident, original, natural in its every-day proportions. This fault however is still more conspicuous in the French dramatists who succeeded him, whose portraits, are, in most instances, only coarsely drawn caricatures of nature.

The other dramatic writings of Regnard, in five acts, are,—
1, 'Le Distrait,' which appeared in 1697, and is taken from one of the characters of La Bruyère. This piece failed on its first representation, but was produced in 1731, reproduced in 1731, reprinted in 1733, and, is not now in the French stage with considerable success. 2, 'Démocrite' (1700). 3, 'Les Ménecomes' (1705); a comedy dedicated by the author to Boileau on a reconciliation with him which his friend had effectuated; between these two poets there had been a long literary warfare [Boileau, P. C.]; it is rather an imitation of the Médécines of Rotrou than of the antient comedy of Plautus. His shorter pieces are mostly in prose; the principal of them are,—1, 'Le Divorce,' in three acts (1688). 2, 'La Descente de Mezétin aux Enfers' (1689). 3, 'L'Homme à bonnes Fortunes' (1690); Regnard has also written a criticism on this comedy in a small piece of one act which appeared in the magazine of the year. 4, 'Les Enfants d'Érantes' (1690). 5, 'La Coquette' (1691); all in three acts. 6, 'Les Chiens' (1692), four acts, and several one acts. 7, 'Le Sérénade.' 8, 'Le Foire de St. Germain,' &c. He also wrote an opera called 'La Malavie,' in five acts (1699), the music of which is by Campra, and a tragedy called 'Sapor,' which has not been represented. His other writings are some Epistles and two Satires, one of them directed against Boileau, another against husbands, which have not been much noticed. Regnard has also composed a relation of his various travels, and the Provençal already alluded to.

The best editions of his works are those by Lequien, published in 4to., 6 vols. 1721, and by Craulet in 1825 and 1826, 6 vols. 8vo.

REGULATORS OF MOTION. Fly wheels are the means usually employed to render the movements of machines and clocks more regular. To some considerable extent, the applications of these have been described under WHEELS, (P. C. p. 316, col. 2), and under STEAM-ENGINES (P. C., p. 447, col. 1). Pendulums, as regulators of motion for clock work, are described under PENDULUM (P. C.); and the Governor, by which the supply of steam is regulated, has been described under STEAM-ENGINES (P. C., p. 415, col. 1). Some account of air-vessels for regulating motion in the tread-wheels, which are employed in prisons, has been given under AIR-VESSELS (P. C. S.), and it may be added that a particular kind of fly has been occasionally used for the like purpose. This consists of a vertical rod or shaft about 20 feet high, carrying at its upper extremity, on opposite sides, a long rectangular frame, which is provided with shutters turning on hinges; by the revolution of the shaft these frames turn and cause the shutters to open and close the mouth of a guttering air-vessel. In the motion of the tread-wheel becomes too rapid, the diverging balls cause the shutters to close, and thus the resistance of the air is diminished. When the movement of the tread-wheel become too slow, the balls collapsing allow the shutters to open, when the resistance of the air is diminished and the velocity of rotation increases.

REICH, ANTOINE-JOSEPH, a musical composer and theorist, was born at Prague in 1770, and having in his infancy lost his father, was educated first by his uncle, and finally at the university of Bonn, where he very successfully completed his studies. Having been appointed maître de chapelle to the Elector of Cologne, placed his nephew in the same service. On the French invasion in 1794 Reicha sought refuge in Hamburg, and there composed an opera, 'Ondine, ou les Francais en Egypte,' but it was not represented. He then repaired to Paris, in 1798, but failed in his endeavour to obtain a hearing for his work, on account of the feebleness of the drama. However he there produced a grand symphony which met with applause. In 1802 he proceeded to Vienna, and resided six years in that capital, enjoying the friendship of Haydn and Beethoven. During that period he published an Oratorio, and a collection of Cantatas, and at an annual concert of the orchestra of the Prussia, who was a superior performer on the piano-forte, and who desired instructions in composition from Reicha, he prepared to visit Berlin; but the death of that accomplished and有能力的 musician obliged him to change his plans. He returned to Paris, and gave a course of lectures on composition, which were well attended; and some quintets for wind-instruments which he there produced, were much admired.

Reicha, Capriccio de Poesie, Passamezzo, from the Opéra Comique, was allowed only a single representation, and that a stormy one. In 1816 he produced, at the Academie Royale de Musique, 'Nathalie, ou le Familier Suiss,' and in 1823 'Sappho.' But this able theoretician and learned harmonist had not the talent for creating melody, which genius alone can produce; and he might with propriety have said to his disciples, 'I pursue my precepts, but not my examples.' He then prudently renounced the composition of operas; and having been named professor at the Conservatoire de Musique, on the death of Mehl, in 1818, there he attracted a numerous class of pupils, many of whom, crowned by the Institute, have since become highly esteemed masters. He originated a method of instruction more clear and precise than any that had been in use; and the publication of his didactic works, which soon made them known in most parts of Europe, and according a considerable degree improved the study and advanced the knowledge of music. These opened to him the doors of the Institut de France, in May, 1835. Unfortunately for the administration of that science, his death took place in May, 1836. His chief works on the theory of music are,—1, 'Traité de Mélocie,' &c. 4to., 1814; 2, 'Cours de Composition Musicale,' 4to., 1818; 3, 'Traité de l'harmonie, du Cours pratique à deux Parties,' 4to., 1840; 4, 'Art du Compositeur...
Escutcheons and as narrow piers between the columns, so that the middle one predominates, both as to the quantity of surface: the openings occupy, and the architectural character occasioned by it. One of the earliest importations of the Renaissance into this country, Longleat House, Wilts, erected by John of Padua, 1567, for exalted family of 'taste' displayed in it, is an instance of such mode of composition, and shows how greatly the borrowed style was transplanted into the English house, even when treated faithfully with regard to details, among which may be reckoned the orders themselves, which amount in fact, when so applied, to no more than such.

One deviation from the Italian practice was the frequent employment of coupled columns or pilasters, which was in some cases (as at Wollaton Hall) caused by the necessity for wider piers between the windows, at the same time that the intercolumns were completely occupied by the windows, which last, it should be observed, retained their Tudor or English character, being very spacious and divided by mul-
attested the magnificence if not the refinement of that age.

As a retreat for himself in the immediate vicinity of his capital, Francis built (about 1630) the Château de Madrid in the Bois de Boulogne, whose façades were decorated with coloured glazed bricks or enameled tiles, constituting a species of polychromic decoration. Of the building nothing now remains, it having been taken down at the end of the last century; but another architectural specimen of the same period exists in the case of the house of the late Sir Edwin Chadwick, of Nor- 

tinal, which has added some polychromic *fayence* decoration, plans, elevations, and sections, are given in Normand’s *París Moderne*, but being only in outline, a great deal of the effect is lost in them. The palace of Fontainbleau itself, in its interior at least (now restored by Louis Philippe), records the magnificence of Francis, his taste for splendour, and his liberal endowment of art.

In Germany, the castle or rather palace of Heidelberg would, if complete, have been a most gorgeous pile in the Renaissance style, as it showed itself in that country; and though now a ruin, the principal portion of the exterior is in such excellent condition as to admit us to a man’s house in a series of architectural engravings—and it is infinitely worthier of being so recorded than are the mere shapeless fragments of buildings—a few blocks of stone and columns which had been cut down for other purposes, and which are here because discovered where they were not before known to exist.

The architecture of Spain at various periods is as yet so imperfectly known that very little is known of its Renaissance edifices; but from the views of some of them in the *Español Artístico*, that country would appear to contain several interesting and striking specimens of the kind; and among them may be mentioned, as deserving of particular notice for the elegant taste it displays, the upper gallery of the cloister of the Convent of Huerta.

We may conclude this imperfect sketch by observing that the two little volumes which contain all that is worth studying in the study will enable us to avoid what was faulty in it, and to catch some of its freedom and spirit without falling into the licentiousness for which it may justly be censured.

REPEAL OF STATUTES. [Statutes, P.C.

REPRESENTATION. [Denby, P. C.] REPTON, Humphry, the celebrated practitioner and writer upon his art, who first assumed professionally the title of Landscape Gardener, was born at Bury St. Edmund’s, where his father held the lucrative situation of collector of Excise, May 2nd, 1769. After being placed first at the grammar-school at Bury, and then at that of Norwich, he was sent to Cambridge, where he entered on the business of a merchant in the city of London, in the year 1764; a suitable place enough for the future merchant or manufacturer who was to be intent on trade—which seems, according to the best authority, to have been his father’s chief ambition for him—but almost the worst for the future landscape gardener, Dutch gardening being the very reverse of nature and picturesque landscape. At the age of sixteen he returned to England, and was placed in a merchant’s counting-house at Norwich, but all his leisure was devoted to poetry, music, and drawing. At the age of twenty-one he married, and was set up in business as a general merchant by his father, and for a while affairs prospered with him; but after a few years took an unfortunate turn, owing to losses of vessels at sea, and other circumstances in trade; whereupon his health both his parent’s, he determined upon, following his own inclination. He accordingly settled at Sustead, near Aylsham, in Norfolk, where his sister resided in a house left them by their father. The change was to him a delightful one, and there he passed five years of almost uninterrupted happiness, occupying himself with farming experiments, gardening, and the study of rural scenery.

An event however occurred in 1783, which promised to open a widely different career from that in which he had lived so far, and that in future distinguished himself; for in that year his friend and neighbour Mr. Wyndham of Felbrig was appointed secretary to the Lord-Lieutenant of Ireland, and Repton, feeling that as the opportunity was presented for the exercise of individuals of increasing family, agreed to accompany him as his confidential secretary. The flattering expectations thus suddenly raised, were as suddenly blighted; for his patron gave up his post almost immediately; and Repton returned to Suffolk and domestic privacy. There however he did not long remain, for compelled to retreat, he took a small house at Harrett, Essex, to which he became so much attached as ever to reside there. Just at this time (1784) he became acquainted with Mr. Loudon [Loudon, P. C. S.], and whose project he aided not only by his advice and personal exertions, but by advancing a considerable portion of his small remaining capital. Yet though the scheme prospered, and the author of*Repton’s Essays on the Theory and Practice of Landscape Gardening,* 4th ed., 1803; *Inquiry into the changes of Taste in Landscape Gardening,* 5th ed., 1806; *Designs for the Pavilion at Brighton,* folio, 1808; [though these designs are said to have miscarried, and to have been rejected, as they contained no buildings for the accommodation of the Prince of Wales, and were, like the building afterwards erected by Nash, in a fancy Oriental style, they were not adopted]; and *Fragments on the Theory, &c. of Landscape Gardening,* 4th ed., 1816, in which he was assisted by his eldest son. These different publications on his art, which at their original price cost collectively 20s. 2d., were reprinted in 1840, by the late Mr. Loudon [Loudon, P. C. S.].

The octavo volume contains a portrait and memoir of the author from autograph memoranda (which has here been made use of). Though this compressed and economic edition has not the attractions of the larger folios, the plates, which are taken from the best engravings, and the colouring plates, the same subjects being shown in small woodcuts, it is far more convenient as a volume for perusal and study, and moreover contains several notes and remarks by the editor.

REPUBLICATION. [Wills and Testament, P. C.] RESEDA’CE, a natural order of plants belonging to the class of Exogenia. It has a many-parted calyx; the petals unequal, oblong and fleshy; the stamens sessile; the anthers 2-lobed, opening longitudinally; a 3-lobed 1-located many-seeded sessile ovary, scarcely closed, usually with 3-6 parietal filaments inserted into the disk, the filamenta erect, the anthers 2-lobed, opening longitudinally; a 3-lobed 1-located many-seeded sessile ovary, scarcely closed, usually with 3-6 parietal
placenta, sometimes surrounding a free central ovule-bearing body; 3 granular, acumen stigmas; campylocarpus, or amphiophylo ovules; the fruit dry and membranous or succulent, opening by valves or by splitting down the back of the placenta, forming a round placenta, or even hooded and 1-seeded; the seeds several, reniform, with a taper accrate embryo without albumen, and a radicle next the hilum. The species of this order are soft herbaaceous plants, or a few small shrubs with alternate entire or pinnately divided leaves, and minute gland-like stipules. The flowers in racemes or spikes. The genera are widely distributed in the Mediterranean and the adjacent islands.

A few species occur in the north of India, the Cape of Good Hope, and California.

No one of the species possesses any active properties. Reseda latifolia is the Woold, Wood, or Weld, that is used in dyeing.

Rhodea odorata is the common Mignonette.

It has lanceolate bluntish entire or trifid leaves, a 6-parted calyx equal in length to the petals, which are finely cleft into many club-shaped divisions, the two lowest simple, the capsules 3-toothed. It is a native of the North of Africa and Egypt, but its delicious fragrance has caused it to be cultivated all over the world.

It is naturally a herb, but when trained in the greenhouse it becomes shrubby. This plant is in full flower in March, which two more scarce and extensively cultivated.

The seeds should be sown in pots or transplant into pots 4 or 6 plants to a pot 4 inches in diameter. To obtain plants for flowering from December to February, a seedling should be potted when 2 or 3 inches high and the plants potted in September. The crop for March, April, and May should be sown in pots not later than the 20th of August; the plants from this pot will not be ready for planting out until the first of December. If the plants be kept in pots to rain whilst they are young; they must be protected from early frosts like the winter-crop; they are to be thinned in November, leaving not more than 5 or 10 plants in a pot; and at the same time the pots should be sunk 3 or 4 inches in some old tan or coal-ashes and should be covered with a frame, which is best to place fronting the west, for then the lights may be left open in the evening, to catch the sun whenever it sets clear. The third or spring crop should be sown in pots not later than the 25th of February.

These must be placed in a frame on a gentle heat; and as the heat declines, the pots must be let down three or four inches into the dung-bed, which will keep the roots moist, and prevent their leaves turning brown from the heat of the sun in April and May. The plants thus obtained will be in perfection by the end of May and be ready to succeed those raised by the autumn sowing (Hort. Trans., vol. 2).

The arborescent plant is called Tree-Mignonette. It may be propagated by seeds or by cuttings, which readily strike root. The young plants should be potted singly, and brought forward until they can be planted out in the establishment. The plants should be stood in a cool nursery, stick and all side shoots should be pinched off. As the plants attain a greater size they should be shifted progressively into larger pots. The plant being 2 years old, is of the species Reseda, 4. 128.

R. sudaria, a native of the south of Europe, with pinnatifid leaves and linear-lanceolate segments, trifid petals and 3-4- lobed capsules, is the order Reseda pluricostata. 5. 160. It grows at the present day on the way-sides in Attica and Corinth.

R. laten and R. fruticulosus are British species as well as R. latifolia. The former has 6 very unequal petals and 3-left or pinnatifid leaves. It grows in waste places in chalky and limestone districts. The second has 5 nearly equal petals, with pinnatifid leaves, and grows in waste sandy places near the sea.

(Babington, Manual of British Botany; Don, Gardener's Dictionary; Barnett, Outlines of Botany; Lindley, Vegetables for Kitchen and Garden; Bourne, Vegetable Kingdom.)

RESULTING TRUSTS. [Trust and Trustee, P. C.]

Rham, William Lewis, was born at Utrecht, in the Netherlands, in 1778; and of this country his father was, we believe, a native, but his mother was Swiss. He entered Dr. Rham's house one to train in early life. He studied for some time at Edinburgh, with a view to the medical profession, but eventually he became his destination, and he entered at Trinity College, Cambridge. In 1806, he was twenty-eight years of age, and he was the first to publish his name appears on the Tripods as tenth wrangler. In 1808 Mr. Rham was presented by his college with a prize of fifty pounds for the living of Winkfield, Berkshire; and a few years afterwards the Nassau family presented him to that of Ferefield, in Norfolk. He died unmarried at Winkfield, after a short illness, on the 31st of October, 1843.

The life of Mr. Rham was characterized by active and unremitting usefulness as a parochial clergyman. He was the friend and confidant of the poor in the several parishes under his care, and was known to many of the inhabitants in country parishes, the young were taught not only the elements of knowledge, but were instructed in useful arts, and trained to habits of industry. Such were the means by which he endeavored to promote the best interests of his parishioners.

The school which Mr. Rham founded at Winkfield is that described by Mr. Tremenheere, in his Report to the Council of Education in March, 1843—'This school was established in 1835 for 50 boys and 50 girls. The building consists of a house for the master and mistress, two schoolrooms, a work-shop, shed, etc. It is surrounded by two acres of garden, to which two more acres are added. The garden is cultivated, by the master and the boys, with the various agricultural crops, according to the most approved method and regulations. The industrial work originally projected for the use of the boys was—garden work, basket weaving, and mat making; for the girls, the usual needle-work, washing, ironing, cooking, and the common household employments, under the direction of the mistress. The manual instruction of the boys in the workroom has been little kind; but the garden presented very satisfactory evidences of their skill and industry. It is cultivated in common, with the exception of small plots about twelve feet square, which belong to the boys, and of the produce of which they keep a debtor and creditor account. The produce of the rest is sold to persons who take it off to market, and the proceeds are carried to the general account of the establishment. The crops were abundant, and more varied than it is usual to see in common gardens. Something was found to fill up every space, and to suit every spot,—either one of the ordinary garden crops, or some of the useful herbs, or some kind of plant or flower; and thus a lesson of considerable use to a cottager is early communicated, in the habit of making the most of even the smallest portion of ground, however apparently unpromising. The practical instruction, and the practical example, of which the pupils here have the benefit in their garden-work, will be greatly extended when the agricultural operations commence in the field just added to the school grounds. We shall enjoy the advantage of pursuing all the details of the most skilful husbandry, under the same good guidance, namely that of the benevolent originator of this institution, the Rev. W. H. Rham, so well known as an accomplished agriculturist. The boys will, indeed, from that period be able to offer to the children of the agricultural labourer a course of practical training in garden and farm management of no ordinary excellence.'
of the present day on the subject of agriculture, Mr. Rham was eminently fitted, by his excellent judgment and sound sense, to be useful to the country in the existing state of its agriculture, economy, and probably, we are one of the great industrial branches of the Royal Society of Agriculture. He was a member of the council and the committee of the Royal Society of Agriculture, from its formation in 1833. A volume entitled 'The Dictionary of the Farm,' which contains his views on all the principal subjects of interest to the agriculturist, has been published by C. Knight and Co. It is compiled, with the assistance of the late Mr. J. H. Rodwell, who also contributed to it, and which he wrote in the 'Penny Cyclopaedia,' the first article [Art. NATURAL, T. C.] being contributed by him in 1833, and the last (Yorkshire Agriculture, P. C.) in 1843, only a few weeks before his death. He was also the author of 'English Husbandry,' a short work written for the 'Farmers' Series of the Library of Useful Knowledge.' This work was founded on a pedestrian tour in Flanders, in which, for many weeks, he walked from farm to farm, enjoying the rough hospitality of an industrious population, speaking their language readily, and entering into their pursuits with the zeal of a skilful and sympathetic friend. The Essay on the Analysis of Soils, for which he obtained the prize offered by the Royal Society of Agriculture, is published in the Society's 'Journal,' which also contains some other valuable contributions from his pen. Not long before his death he had also commenced papers on agriculture and rural economy in the 'Gardener's Chronicle,' edited by Dr. Lindley.

Mr. Rham's correspondence on agricultural subjects, both in this country and on the Continent, increased his experience in the science; and he gave his opinion with the utmost readiness. Nor did he stop here, or remain content with having acquainted himself with extreme urgency and courtesy, but with uncommon ability upon which he had consulted very carefully. Great was the respect paid to his opinions, he gave them without the least dogmatism. In one of his last communications to a valued friend (Joshua Rodwell, Esq., of Alderton Hall, Suffolk), Mr. Rham has expressed a characteristic of his unassuming disposition and his deftience to humble practical experience, which men who have acquired a scientific knowledge of literature do not so apt to despise. 'Whatever,' he remarks, 'great chemists may say about the component parts of soils, I am persuaded they can never decide as to the aptitude of any soil to produce a crop still experience has shown it. I believe we have all overlooked some electro-magnetic qualities which we have not yet instruments to measure.' It was this reliance upon experience, in connection with a bold and searching investigation of theory, which rendered Mr. Rham's writings so well adapted for the practical man at the time. In the eagerness for improvement, a writer is best calculated ultimately to benefit his country who unites scientific attainments of a high character with a rational degree of richness of style.

RHAMNUS. [Artica, T. C.]

RHAPSODY (Rhaphis) is a poem sung by a rhapsodist, and is generally applied to detached parts of the Homeric poems, or the Odyssey, when composed by rhapsodists. But the word rhapsodist properly signifies one who sews or fastens things together; and it was especially applied to those who arranged or are supposed to have arranged the parts of the Homeric poems and of other old poems, so as to make one entire work of them, and who went about from place to place to sing and recite these poems. (Lindley, Flora Medica.)

From the Greek Soils, for fio, fio, and pirv, a measure, is an instrument by which the force of an electric, galvanic, or magnetic current may be measured. The word was first proposed by M. Pellet as a synonym for galvanometer; and it has since been employed by Professor Wheatstone in a general sense, together with Rheoscope, denoting an instrument by which the existence of an electric, &c. current may be ascertained; and Rheomotor, expressing any apparatus, as an electrical or galvanic battery, by which a current of that kind is originated.

The rheometer or galvanometer employed by Mr. Wheatstone is a glass cylinder resting on a stand, and containing within it a large, polished needle, which has been employed by Professor Wheatstone in a general sense, together with Rheoscope, the color of the gelatine, and other properties of the needle, which have been employed by Professor Wheatstone in a general sense, together with Rheoscope, denoting an instrument by which the existence of an electric, &c. current may be ascertained; and Rheomotor, expressing any apparatus, as an electrical or galvanic battery, by which a current of that kind is originated. The rheometer or galvanometer employed by Mr. Wheatstone is a glass cylinder resting on a stand, and containing within it a large, polished needle, which has been employed by Professor Wheatstone in a general sense, together with Rheoscope, the color of the gelatine, and other properties of the needle, which have been employed by Professor Wheatstone in a general sense, together with Rheoscope, denoting an instrument by which the existence of an electric, &c. current may be ascertained; and Rheomotor, expressing any apparatus, as an electrical or galvanic battery, by which a current of that kind is originated.

RHINANTHUS (from Rhin, a nose, and anthos, a flower), a genus of plants belonging to the natural order Aphanthaceae. They are regularly 2-celled, small subulate bracts and bracts of a hypogynous and 2-locular, in a long slender tube, the upper lip narrow, the lower trifid, with equal segments; 2 stamens inserted in the throat of the corolla, the anthers 2-celled, short, small, with one cell placed above the other almost in a line; a clavate capsule much compressed at the base, with the commissure of the valves in contact and sessile; the upper part 4-seeded, or by abortion 2-seeded; the dissepiment complete, adnate; the seeds ovate, bicorne, augmented with hooks which are concave and obtuse.

R. communis is a native of the continent of India, with opposite stalked broad-lanceolate obtuse leaves, above smooth, below a little reticulate; and sub-biennial; the flowers below a little inflated; the corolla, the outer or throat, 2 to 4 inches long and from 1 to 2 broad, and a feathery ring surrounding the base of the ovary. The roots of this plant are boiled in milk, and are reckoned by the natives of India an aphrodisiac. In conjunction with the cinnamon and pepper they are used as an external application for ringworm.

(Lindley, Flora Medica.)
R. major has linear-lanceolate serrate leaves; the flowers in spikes, the calyx glabrous, the lobes of the upper lip of the corolla oblong; B. brasica inciso serrate, with an attenuated point, the seeds with a very narrow membranaceous border. This is the plant of British botanists, but the R. major of Koch has a broad membranaceous margin to the seed, and is a different plant from the British R. major. This is the corolla as prominent as the lateral lobes. This plant is found in meadows and corn-fields in the North of England, and also in Lancashire.

Several other species of this genus have been described, Koch, in his 'Flora Germanica,' bas five. R. minor, the R. rutila gallii above described, R. major, R. eletorophor, R. anagastica, and R. brasiliana. (Don, Gardener's Dictionary; Bebbington, Manual of British Botany.)

RHYNZODUS, a genus of fossil fishes from the carboniferous strata of Scotland. (Owen.)

BIODEA, a genus of fossil Ferns proposed by Presl.

The species belong chiefly to the Coal formation.

RHYNCHOSAURUS, a genus of fossil reptiles. It was found in the new red sandstone of Grinimal in Warwickshire. (Owen.)

RHYNCHOSPORA, a genus of plants belonging to the natural order Cyperaceae. It has few-flowered spikelets, 6 to 7 flowers to a spikelike, long and slender, the nut compressed, convex on both sides, crowned with the dilated base of the style. There are two British species; R. alba, not uncommon on turf, and R. fusca, a rare species found in Cornwall and in Ireland. (Bebbington, Manual of British Botany.)

RIBALTA, FRANCISCO, a distinguished Spanish painter of the school of Valencia, was born at Castellon de la Plana in 1551. When very young he fell in love with his master's daughter, but the father (his name is not mentioned) would not consent to a marriage, on the plea that Ribalbta was not sufficiently advanced in his profession. Upon this he determined to go to Rome, and his mistress, to support his faith and to. At Rome he studied the works of Raphael, and particularly Sebastian del Piombo, and, according to Cean Bermudez, those of the Carracci also; but this is an error; none of Ribalbta's works were seen in Rome before 1600, some years afterwards Ribalba must have left it.

Upon his return to Valencia after an absence of three or four years he immediately repaired to the house of his master, who was absent; but upon his entrance in his study was standing an unfinished sketch, which the young painter as rapidly as possible completed in the presence of his still faithful mistress, and immediately retired. The father was much surprised at what he saw, and asked his daughter who had been there, at the same time observing, 'If this were your lover, willingly should you marry him, but not the poor Ribalbta.' 'Ribalbta himself bas done it,' said his daughter, and of course the master was fully satisfied. Ribalbta soon obtained great reputation. His first public work was the Last Supper, ordered by archbishop Don Juan de Ribera for the grand altar of the college of Corpus Christi, at Valencia, and finished in 1554. He was also the painter of the place Pedro Munzo as St. Andrew; and as Judas, a shoemaker, the master of the name of Pradas, whose veneration was a nuisance to him. He died in 1598, and was buried in the church of San Juan del Mercado, in Valencia.

Ribalbta's design was correct and vigorous; he was a good anatomist; and his compositions are often grand. In colouring also he was generally good, much resembling Sebastiano and Titian, though occasionally dry; but the works of some of his principal scholars, as Castanial and Bous, are sometimes attributed to him. His works are or were very numerous in Valencia, and there are several at Castellon de la Plana, and Madrid; and some at San Ildefonso, Toledo, Zaragoza, Andilla, Algemesi, Torrecat, Portaceli, Morilla, and Carcascante.

The Entombed' by Ribalba, in the cathedral of Valencia, is an excellent work, and there are also many admirable pictures by him in private collections in Valencia, as those of the Conde de Parcent, and the Marques del Rafol. The Corey Collection, in London, contains a very fine picture of Ribalba and a banana tree. The museum of Ribalba. It was founded by Ribalba's patron, the Archbishop Juan de Ribera, commonly called 'El Santo Ribera.' He was canonized in 1797. Ribalba is to be seen to great advantage in the church of San Lorenzo, where he contains some of his greatest works, as 'San Vicente de Ferrer visited on his sick Bed by our Saviour and Saints; the 'Last Supper, already mentioned; and a 'Holy Family.' In other parts of the same building are 'Christ in the Garden of Olives;' 'Christ at the Column,' and 'the Acts of Pilate' in a twon torb. There are also some works by Ribalbta in the Museo (the former Carmen) of Valencia. The pictures of the church of the small hallowed of Andilla are also among the best works of Ribalbta. At Seville, in the church of San Martin de las Monjas, is also a noble picture by Ribalbta of Christ descending into Hades. In the church of his native place Castellon de la Plana there is still a 'Purgatory' by him; other fine works that were in his day have disappeared. The picture of 'Christ bearing his Cross' in Magdalen College, Oxford, of which there is a print by Sherwin, and which was ascribed to Guido, Lodovicio Caracci, and to Mondei el Divino, is, according to Dr. Forth, certainly a picture by Ribalbta. It is in the chapel altar-piece, and was presented to the college by William Freeman, of Hamlets, in Hertfordshire; it was originally brought from Spain by the last duke of Ormond from Vigo in 1797.

Juan de Ribalba, an able painter, and of great promise, was the son and pupil of Francisco, but he died in the same year as his father, aged only 21; he was born in 1567. Ribalbta also, or Spagnolo, is said to have been the pupil of Ribalbta.

(Cean Bermudez, Diccionario Historico de los mas illustres Profesores, etc.; his fellow travelers in Spain, etc.; English Connoisseur; Oxford Guide.)

RIBGRASS. [PLANTAGINACE. P.C.]

RICCIO, DOMENICO, called Il Brusasorci, a celebrated Venetian painter. He was born in Verona in the year 1655, a pupil of Gildino, and is supposed also to have studied under Titian, in Venice, where he at least studied his works and those of Giorgione. He is called the Titian of the Venetian painters. His name of Brusasorci (rat-burner) was acquired from his father Giacomo Riccio, who invented a rat-trap, and had what he cooked in his own house burnt, whence he was commonly called by his neighbours Brusasorci, a name which was descended to his children and grandchildren. Among Domenico's first and principal works in Verona were the frescoes of the Palazzo de' Murari, near the Ponte Nuovo, which he decorated exteriorly in chiaroscuro with scenes from the fable of Cupid and Psyche, and the marriage of Emperor Claudius (the Lago de Garda) with the nymph Charis represented by Garda; he painted numerous nymphs, with Hymen, as he is described by Catullus (Carmen 61-2), and all the characteristics of rural and sylvan life, pastoral and real; and also in distinct compartments extensive groups of marine deities, and other corresponding mythic evocations, for all of which he received only forty ducats. In the Palazzo Riodli he painted the celebrated .valence of Clement VII. and Charles V., at Bologna, on the consecration of the emperor, in which he introduced many portraits; these frescoes are still in preservation. Riccio painted also many excellent works in oil, including several large figures of saints for several churches in and near Verona, and other works in the ducal palace in Mantua. Venuses and nymphs were also favourite subjects with him; and such pictures frequently occur in picture galleries.

Ricci, of Verona, 1612—1693.

Felice Riccio, or Brusasorci, his son, was also a distinguished painter; but having studied under Ligozzi at Florence, he painted in a different style from his father: more delicate, but with less power; he was a good portrait painter. He died in 1605, aged 63. His sister Cecilia Brusasorci was also an excellent painter of portraits. Giovanni Battista Brusasorci, another son of Domenico, was painter to one of the German emperors, and died in Brussels.

(Ridolfi, Vite de' Pittori Veneti, &c.; Dal Pozzo, Vite de' Pittori Veronesi; Lanz, Storia Pitteria, &c.)

RICHARDSON, WILLIAM, the son of a parish clergyman in Perthshire, was born in 1743. He was educated for the church in the university of Glasgow, became tutor to the sons of Earl Cathcart, and spent two years with these youths at Eton. In 1770, when he returned to Scotland and basillar extraordinary to Russia, he accompanied the company to St. Petersburg, where he acted for four years as the early private secretary. In 1778 he was appointed professor of German in the University of St. Andrews. In 1783 he was assistant and secretary of the office till his death, which took place in 1814. Professor Richardson was a highly popular and successful teacher, and also published several literary works of some celebrity. He was the author of a book of tales, the translator of a ring, and the author of two dramas, of 'Anecdotes of the Russian Empire,' and of a series of periodical essays called 'The
Philanthropy.' He was best known however for a series of Essays on the principal Characters of Shakspere, which appeared in three successive volumes beginning in 1776, and were in 1797 collected into one volume, which became very popular, and was rapidly sold. There are several which show considerable critical talent, and some eloquence in writing: their chief fault is the depreciatory spirit in which they treat the great poet, and which has exposed them to severe censures from Mr. Knight and some other recent critics.

RICKMAN, THOMAS, a distinguished writer on Gothic architecture, whose work has become a standard authority in a branch of literature where there is so much to be done, is a very well known to his followers, and perhaps to others also. His first work, published in 1801, was a Series of Papers on whose personal situation is so little known; but it is very remarkable; for though neither his education nor his first pursuits in life were calculated to direct his attention to the study of architecture, while the religious tenets in which he was brought up by his parents (those of the Society of Friends) were ill fitted to inspire a taste for that particular branch of the art which he especially cultivated, he not only made it his study, but when he had reached the meridian of life, took up architecture as his profession, and obtained extensive practice.

He was born at Maidenshead June 8th, 1776, and brought up by his father, who was a surgeon and apothecary, in that town, to the same profession. He went in 1797 to London, where he became for a while assistant, first to Mr. Stringer, chemist to the royal family, and next to Mr. Atkinson, in Jersey. In the year 1798, liking the determined course he was pursuing, he changed his situation only that he might obtain admission into the employment of Messrs. Day and Green, extensive grocers, at Saffron Walden. His residence at Saffron-Walden was not, however, very promising, and occasioned, with his wishes of his father, who was anxious that he should complete his medical education, he went again to London, and 'walked the hospitals' after which he returned, in 1801, to his father, who was then settled at Lewes, but did not remain with him above two years, when he repaired again to the metropolis, and engaged himself as clerk to a corn-factor,—a step likely to lead him further from than bring him at all nearer to his ultimate destination. Nevertheless it proved a stepping-stone to him, so far as he became a partner in the business. In 1808, about the time of the death of his first wife (his cousin Lucy Rickman, to whom he had not been married above a year), he removed to Liverpool, where he made another change, for he took a situation in the counting-house of one of the principal insurance-brokers there. Uncongenial and unpromising as it apparently was in itself, this new situation proved the making of his fortune and fame; for as the attention to business it required occupied him only a few hours in the day, he devoted his leisure to the study of architecture. But here there is evidently a gap in this most interesting part of his life, a missing phase of his career altogether in uncertainty as to the influence or impulse which directed him to a pursuit so remote from his habits and employments.

In 1817, however, having once taken up the study he pursued it zealously; examined ancient buildings with diligence,—in a word, educated himself; and perhaps saw all the clearer because he was not encumbered in his inquiries by the prejudices and conventionalities of a professional education. He was also industrious with his pencil, and carefully noted all those distinctions in the different modes of the pointed style on which he founded his valuable system of classification for it. About this period he married his second wife, Christiana Horner, sister to Thomas Horner, the artist who painted the large panorama of London, in the 'Colosseum,' in the Regent's Park.

On the grant of a million for additional churches being made by Parliament, Rickman, who had previously made attempts at original design, became a contractor, and a design sent in by him being accepted, he determined to establish himself as an architect: he quitted Liverpool andremoved to Birmingham, as being in his opinion a likelier situation for obtaining practice from various quarters. Having no practical experience at that time himself, and being unacquainted with the business of the profession, he engaged Mr. E. Hutchinson as his managing assistant in all matters of business, and after his death (1850) entered into partnership with Mr. Hussey.

In 1835 he married his third wife, Elizabeth Miller, of Edinburgh, by whom he had a son, and who survived him. Some years previous to his decease he had had an apoplectic attack, but his naturally strong constitution prevailed against its effects, and he continued to exercise his profession up to the time of his death, which happened March 4th, 1841.

Had Rickman been known only as a writer, his 'Attempt to discriminate the Styles of Architecture in England,' originally published in 1801, and reprinted in 1821, would have deserved a place among the rare volumes of the British Association for Science and Art, but greatly extended as a separate work, and improved in each fresh edition, it would have obtained for him celebrity, for it has become a standard book, and one almost indispensable to the student. Nevertheless it is omitted among those on the subject of Gothic architecture, of which a list is given in Gwilt's Encyclopaedia. The work itself, however, recommended him to all lovers of Gothic architecture whatever their personal literary tastes may have been, and procured him patronage in very influential quarters, where as a seceder he could hardly look for direct censure and employment. It is to be observed however that 'lastly'—by which it no doubt is to be understood when his profession brought him into contact with the clergy,—he withdrew from the Society of Friends. In all probability he had already done so when he was employed at Cambridge and at Rose Castle, the palace of the Bishop of Carlisle, which was restored by him. At Cambridge he executed the new court and buildings (begun in 1827) of St. John's College. Perhaps hardly any individual in the profession has ever completed so many churches as Rickman, and a list of them and of other buildings by him is given in the 4th edition of his book; but, long as it is, that list is incomplete, because it does not come down later than 1835. It also be regretted that it is a mere list, without so much as any dates. This it is to be hoped will still be done, and the list itself completed in the next edition of the work, which we understand has been long in preparation by his biographer, Mr. Hussey. Perhaps a full memoir of Rickman will then be given; and one very desirable improvement it would be to write a descriptive catalogue of his buildings to be illustrated by wood-cuts of them— if not of all, of the best among them.

RIGIDITY OF ROPES. In estimating the powers of machines, it is frequently necessary to take into consideration the effects arising from the rigidity or stiffness of the ropes which pass over the pulleys or the axes of the wheels; and, in order to understand how this condition affects the relation between the moving power and the resistance, let it be observed that when a stiff rope is bent over the upper part of a wheel or pulley in a vertical plane, for example, the weights or powers applied at its extremities may not be sufficient to draw the descending portions into the positions of two vertical lines. Now, if one of the parts of the rope should take such a direction that a vertical line drawn through the weight attached to that part, cuts the horizontal diameter of the wheel or pulley at a point between the centre and one extremity of the diameter, for we are in the same time, the other part should take such a direction that a vertical line drawn through the attached weight cuts the horizontal diameter at a point beyond the extremity of the latter, the distances of these parts, and from the extreme diameters of the pulleys are represented by and respectively, the corresponding weights by W and W and the radius of the wheel by R; the conditions of equilibrium instead of being W = W' will be

W (R - z) = W' (R + z')

But, if W be the weight which by descending raises up the other, the value of z is generally small the distances may be disregarded, so that we have, in the case of equilibrium,

W = W' (R + z') or again, W - W' = W' R'

that is, in order to put the system in a state of equilibrium, the excess of W above W' should be equal to W' R'.

The formula given by Coulomb to express the force necessary for overcoming the rigidity of a rope, or the equivalent of W' R' is

R (a + 4W')

r being the semi-diameter of the rope, a the force arising from the warping or twisting of the rope, and b that which depends on the tension arising from the weight W; the values of m, a and b may be determined by experiments made
RIZ, DON FRANCISCO, a distinguished Spanish painter, was born at Madrid in 1608. He was the pupil of Vincente Carducho, and had an extraordinary readiness of invention. At the age of twenty inclusive, Rizi was already known as a master; but the time was not yet matured for such superficial and incorrect: still his readiness to design and facility to execute ensured him a brilliant career. It was not till 1656, however, that he was appointed principal painter to Philip IV.; and he held the same place under Charles II., who gave him the additional place of deputy keeper of the royal keys. He was appointed in 1659 painter to the cathedral of Toledo, a post often in Spain more important than that of painter to the king, for he has the charge of all existing works in the cathedral, and generally the execution of all new works undertaken in his time, which in Spanish cathedrals has at one time numerous and important. Francisco Rizi is one of the most distinguished of those from whom the decline of painting in Spain is attributed, through the more superficial attractions of his works; and he is said also, by his eminence in the list of the theatre of Buenaventura, to have been equal in the arts of the altar. At the expiration of his period, Rizi's last work was a sketch for the great altar-piece of the Retablo de la Santa Forma in the Sacristy of the Escorial, which Charles II. ordered for the veil of the magnificent tabernacle and altar, which Rizi had also assisted in making, to contain the Host (La Santa Forma). The subject was the ceremony of the Crowning of the Host by Charles II. in 1684; but Rizi died the following year at the Escorial, having only executed the sketch; the picture was painted by Coello from a sketch of his own, and it is one of the finest pictures in Spain. [Coeleo, Claudio, F. C. S.]

The Host, or the Roman wafer which Rizi died at Gorkum in 1655 when tranquilled on the shoulders of Zwingli. Rudolf II., Emperor of Germany, gave it to Philip II. of Spain, whether it was transported in the world private churches, or was in the present gorgeous altar and tabernacle for its reception, and the present altar-piece is the ceremony of its collocation. The altar is inscribed—En magnis operis miraculis, intra sancta envoles, altaeque tabernaculis suportatae! In the Host, or the Roman wafer, the wafer is exhibited for adoration, the picture, which forms a veil, is let down, and is accordingly much injured. The French, under La Houssaye, who pillaged the Escorial in 1808, carried off an altar and the monks hid the wafer in a cell, and it was restored with great pomp by Ferdinand VII. in 1814.

The pictures, both frescos and in oil by Rizi, are very numerous; there are several in the Museo del Prado at Madrid, and many in the churches of Madrid and Toledo, especially in the cathedral of Toledo. FRAY JUAN RIZI, Francisco's eldest brother, born at Madrid in 1656, was also an eminent painter. His principal works are in the Benedictine Monastery of San Martin at Madrid. His design was more correct than his brother's, and his pictures are distinguished for force of light and shade. He retired to Rome and joined the Benedictines of Monte Casino. He was then made an archbishop, in 1675, by the pope Clement X., but he died in the same year at Monte Casino before entering upon the duties of his office. (Coeleo, Claudio, F. C. S.; Ford, Guide for Travellers in Spain.)

ROADS. In Scotland the public highways used for purposes of general transit throughout the country, and suited for the use of vehicles, are under several different kinds of management. The country in general, with the exception of some Highland districts, is penetrated by turnpike-road, managed by district trusts in terms of local statutes. These are interpreted along with the Act 1 & 2 Wm. IV. c. 43, for the general regulation of turnpike-roads. According to returns of the rents of the various bars, 'the smallness of the sum at which tolls are occasionally farmed is consequent on the opinion that the Mary's right does not exceed 10/- Thirty-six bars bear to have been let for sums not exceeding 201. each, and the number let at sums between 201. and 100/. is 338.' (Local Taxes of the United Kingdom, published by the Board of Inland Revenue.) It is obvious that in such a system the rent of the bars, which is the sum available for expenditure on the roads, must be small in proportion to the sum paid by the public, as the road is on a revenue annually needed for the upkeep by fire, otherwise. Rizo was decorated with the order of Santiago; he died at Seville in 1626. Antonio's son, Fernando del Rizo, was a good fresco painter. (Coeleo, Claudio, F. C. S.)

M.S. COELLO, Claudio, F. C. S.}

Civil, and the modern roads in the fabric of the parishes, and the proprietors of land in the several Highland counties. The commissioners make an annual report to parliament. By the 4 Geo. IV. c. 56, provision was made for the landed proprietors and the commissioners of supply in the several counties, agreeing to relieve the parliamentary commissioners of the burden of the duty of these Highland roads, and supporting them by the produce of tolls. The law as to footpaths and other roads which do not belong to any of the above three systems, is not in a clear law state in Scotland. The right of transit in such cases is founded on the Roman system (service), a system where the public enjoy it, generally rests on the title of the occupant of some districts or land having a right of pathway through some adjoining place. Sometimes the right is of a personal nature, and the occupation of the work is for the benefit of some tenant on some tenement. At other times it is in the possession of a community, as a village or parish; and in such a case it is not lawful to stop any person who may use the path, on the strength of the title. Such paths are virtually public; but there is no such principle applicable to them as that which regulates the publicity of a highway in England by rendering the parish liable to repair it. ROASTING is that culinary process by which meat is brought from a raw to a cooked state more directly by the action of fire than by any other means except that of broiling. 1 2.
By the latter, the heat is applied immediately and suddenly to the surface, by which it is hardened, so that the juices of the meat are preserved, evaporation being thereby prevented; while by the former the heat is applied gradually, the watery portion is evaporated, as well as the fat melted out to a considerable extent, till the progressive browning and hardening of the surface render the further escape of the juices impossible.

The loss of weight in roasting meat is much greater than by boiling: 'By this latter process, nutmeg loses one-fifth, and beef one-fourth; but by roasting, these meats lose about one-tenth.' In roasting, the fat arises from melting out of the fat, and the evaporation of the water; but the nutritious matter remains condensed in the cooked solid; whereas, in boiling the gelatine is partly abstracted. Roasted meat is also more tender than boiled, and is softer, sweeter, and more easily digested. The best and most tender meat may, however, be rendered hard and indigestible by a careless or ignorant cook. Everybody knows the advantage of slow boiling—absolutely important.' See Dr. Kitchener's Cook's Oracle, in which the most sensible and racy instructions on this head are given.

The digestibility is increased by the meat being well done, roasting it slowly; for thought the latter stage of the meat contains most nutriment, yet it will be less digestible on account of the density of its texture. This is of importance, remember, when it is intended for the diet of convalescents, for whose edified and roost meats are preferable to boiled surfeit.

ROATAN, or Ratan, is an island in the Caribbean Sea opposite the coast of Honduras, one of the states of Central America. It lies between 10° 6' and 10° 10' N. lat., and between 87° 56' and 87° 20' W. long., and extends from east to north-east to west-south-west about twenty miles, or some what more; the width in no part exceeds five miles, which is about its breadth for the greater part of its extent. The area hardly exceeds 100 square miles. This island is one mass of rocks, but covered with a deep soil, which, united to a moist and warm climate, produces an unusual activity of vegetation. It is overgrown with high trees, except at the western end, where there are some savannahs, on which formerly mules and other cattle were raised. The highest part of the rock is 600 feet above the sea-level. The woods abound in deer, wild hogs, gibbonas, pigeons, parrots, and other birds, many of which afford excellent food. The whole coast swarms with fish and turtle. On the southern shores are three small harbours, Port Royal, Dixon's Cove, and Cosan's Cove. This island was discovered by Columbus on his fourth voyage, in 1502. The British formed a settlement here in 1742, when they had numerous settlements on the Mosquito Shore, but it was abandoned in 1783, when the English withdrew their garrisons from the Mosquito Shore. In 1794, when the Crown of St. Vincent were expelled by the English and were compelled to submit, nearly all the prisoners with their families were transported to Boston. But they soon abandoned the island, and passed over to the continent of America, where they settled near Truxillo, in which town their descendants still form the bulk of the population. When Orlando Roberts visited Ratan (1822), it was uninhabited. But it appears that more recently some families have again settled there, under the protection of the government of Belize, especially for the purpose of fishing and taking turtles.

(Handerson, Account of the British Settlement of Honduras, &c.); Orlando Roberts, Narrative of Voyages and Travels on the East Coast and in the Interior of Central America.)

ROEBUCK, JOHN, M.D., the son of a Sheffield manufacturer, was born in 1718, received a liberal education at Northampton under Dr. Doddridge, and subsequently at the University of Leyden, and settled in Birmingham as a physician. Pursuing an early taste for chemistry, he introduced some improvements in the processes of refining gold and silver, and subsequently in connection with M. J. D. Garbett, an extensive refinery and chemical manufactory at Birmingham. He there effected such improvements in the manufacture of sulphuric acid (formerly called vitriolic acid, or pyrolitic acid), and by other modifications of the process, as enabled him to reduce its price from sixteen-pence to four-pence per lb., and thus to render it available for many new and important purposes in small and large quantities. Recently, in connection with Garbett, he established, in 1749, vitriol-works at Prestonpans for the purpose of bringing these improvements into practice, thereby rendering a great service to our rising manufacture. He died in a house which he had built at Carrownearne, where he chiefly designed the furnaces and machinery, calling in the aid of Smaaton, and subsequently of Watt. The first furnace at this establishment, the formation of which constitutes an era in the history of British manufactures, was blown on the 1st of January, 1760. Unfortunately for himself, Roe buck subsequently became the lessee of extensive coal and salt-works at St. commutation belonging to the Duke of Hamilton. For the carrying on of these works, on which he employed nearly a thousand persons, he was obliged to withdraw his capital successively from his other undertakings, and his no средства is now devoted to the production of iron. He is the author of the modern steam-engine, in the first patent for which he had a share. He died on the 17th of July, 1794. In a copious memoir in the fourth volume of the Transactions of the Royal Society of Edinburgh, of which he was a member, it is stated he has been the author of a few papers road before that and the Royal Society of London, and to have published two political pamphlets.

ROELAS, JUAN DE LAS, one of the most distinguished of the Spanish painters, commonly known among Andalucian artists as el Cértico Roelas, was born at Seville, of a distinguished family, about the years 1555 and 1560: his father, Pedro de las Roelas, was a Spanish admiral in 1566. Roelas is styled in documents and in books el licenciado Juan, which signifies, probably, merely that he was a graduate of the University of Seville. Little is known about his education: he is supposed to have studied in Italy, and, from his style, with some of the scholars of Titian in Venice. In 1603 he painted four pictures for the college of Jémez. From 1607 until 1624, he lived chiefly at Seville and Madrid; and in 1616, after the death of P. Castello, he was a competitor for the place of cabinet painter to the king, Philip III.; notwithstanding the many years' service of Roelas's father, however, Bartolome Gonzales succeeded Cas tello. Roelas next painted one of the canvases of the college, but he died there in the following year, April 23rd, 1626. Francisco Zurbaran was the scholar of Roelas. The works of Roelas are very numerous in Seville; and there are still many in the College of Jémez, and there are some at Madrid. His masterpiece is the death or el Trasno of San Isidoro, in the church of that saint at Seville; this is a large majestic composition, in two compartments, common to the communion of St. Jerome by Domenichino, and other Italian pictures, but on a larger scale. In the lower part is the archbishop in a church in the attitude of prayer and about to die, supported and surrounded by his numerous clergy, among which are some magnificent heads; in the upper part of the picture is our Saviour on his throne, with the Madonna by his side, and surrounded by angels; the attention is chiefly directed to the central figure; the picture, it appears, has never been engraved; indeed, very few good Spanish pictures have been engraved, and it is owing to this circumstance that the great painters of Spain are so little known out of their own country. The principal church devoted to St. Isidro is the Sant Iago, in the Capilla de Santiago, in the Cathedral of Seville: the saint is riding over Moors; it was painted in 1609: Bermudes speaks of it as full of fire, majesty, and genius. In the same cathedral is the celebrated painting of glass von Bessa, now in the museum; it is surmounted by the picture of the Conception, by Roelas, in the academy; and by three in the chapel of the University of Seville—a Holy Family, with Jesus; a Nativity; and an Adoration of the Kings: the picture of the Adoration, painted by a monk called Jesus: of Roelas: 'Pethico, who was cousin...
of pictures in Seville [Pacheco, P. C. S.], reproached Rodan with want of decorum in a picture, in the Mercado Calzada, of St. Anne teaching the Virgin to read, for representing some sweeter beauty than he had shown in a principal apothegm in the picture; and also for painting a sheet, intended to wrap the infant Saviour in, who is naked, in the picture of the Nativity, in the chapel of the university.

The second picture of the same series, by Carracci; he is the best of the Andalucian painters in design and composition, and displays frequently a grandeur of form and majesty of character which belong only to the greatest masters; in colouring, he may be compared to the Venetians. His last picture is apparently the Nativity, at Olivaros. Palomo's account of this painter is almost wholly incorrect; he calls him Doctor Pablo de las Roelas.

(Dean Bermúdez, Diccionario Histórico, &c.)

ROEMERIA (named after Dr. John James Römer, professor of botany at Landshut; he was author of several botanical works, and died in 1620), a genus of plants belonging to the natural order Papaveracées. It has 4 petals, numerous stamens, 2-4 sessile stigmas, an elongated 2-4-valved 1-seeded capsule with distinct placents. The species are annual herbs yielding a yellow juice, with violet flowers.

R. Apyride, Hybrid Roemert, a 3-valved erect pod with a few rigid leaves at its extremity. This plant is a native of Europe and the north of Africa, in cultivated fields and vineyards, especially on the coasts of the Mediterranean, in Cambridgeshire and Norfolk. Although now having the appearance of a native, this plant has been probably introduced into this country. Two other species, R. refracta and R. obtusiflora, have been described, the first a native of Tauria, the second of Syria.

(Dean, Gardener's Dictionary; Balfour, Manual of British Botany.)

ROMAN ARCHITECTURE. [CIVIL ARCHITECTURE, P. C.]

ROMAN CATHOLICS AND JEWS. An act was passed on the 18th August, 1846, § 10 Vict. c. 59, intituled 'An Act to restore to the Crown the ancient Jurisdiction over the Established Church, and abolishing all Forborne Power repugnant to the same,' and of an act of the Parliament of Ireland passed in the second year of the same queen's reign, (2 Vict. c. 1, [1]) intituled 'An Act restoring to the Crown the ancient Jurisdiction of the State Ecclesiastical and Spiritual, and abolishing all Forborne Power repugnant to the same,' as makes it punishable to affirm, hold, stand with, set forth, maintain, or defend, as therein is mentioned, the authority, pre-eminence, power, or jurisdiction, of any foreign, spiritual, or ecclesiastical, of any foreign prince, prelate, person, state, or potentate theretofore claimed, used, or usurped within this realm, or any dominion or country being within or under the dominion and authority of his said majesty's dominions, shall diligently and faithfully, having no lawful or reasonable excuse to be absent, endeavour themselves to resort to their parish church or chapel accustomed, or, upon reasonable let thereof, to some usual place where common prayer and such service of God shall be used in such time of let, upon every Sunday, and other days ordained and used to be held as holy days, and then and there to abide orderly and soberly during the time of common prayer, preaching, or other religious service of God there to be used and ministered, upon pain of punishment by the censure of the church, for the same affects persons dissenting from the worship or doctrine of the United Church of England and Ireland, and usually attending some place of worship other than the Established Church: provided always, that no poulney premises shall be used upon any person by reason of his so absenting himself as aforesaid. [Members of the United Church of England and Ireland are still liable to the censure of the church, if they do not attend the services; those who do not assist除外 from these censures if they usually attend some other place of worship. Members of the United Church of England and Ireland are however protected by this act against pecuniary penalties for non-attendance at church; and no person shall be excommunicated, or, upon reasonable let thereof, to some usual place where person or persons inhabiting and being within this realm, or any other the king's majesty's dominions, shall, after the said feast of All Saints, willingly and willingly hearing and being present at any one of the said services, or such services as the king's majesty by the administration of the sacraments, of making ministers in the churches, or of any other rites contained in the book annexed to this act, is mentioned and set forth in the said book, or that is contrary to the same, and every such person, or any of them, by the verdict of twelve men, or by his or her own confession, or otherwise, shall, for the first offence suffer imprisonment for six months, without ball or mainprize; and for the second offence, being like manner convicted and committed for this term, or any term, for one whole year; and for the third offence, in like manner, imprisonment during his or their lives.'

Also so much of the said act as enacts, 'that for the more knowledge to be given hereof, and better observation of this law, all and singular curates shall, upon every Sunday in each quarter of the year, during one whole year next following this foresaid feast of All Saints next coming, read this present act in the church at the time of the assembly, and likewise once in every year following, at the same time declaring unto the people, by the authority of the Scripture, how the mercy and goodness of God hath in all ages been shown to his people in their oppressions and extremities, and at the same time making and putting on record and in writing, such hearty and faithful prayers made to Almighty God, especially where people be gathered together with one mind and heart to offer up their hearts by their prayer as the best sacrifices which Christian men can make.'

Also so much of any act or acts of the parliament of Ireland as may have extended to Ireland the provisions of the said act of the fifth and sixth years of the reign of King Edward the Fifth, as far as the same is applicable to Ireland.

Also so much of an act passed in the first year of the reign of Queen Elizabeth (1 Eliz. c. 1), intituled 'An Act to restore to the Crown the ancient Jurisdiction over the Estate Ecclesiastical and Spiritual, and abolishing all Forborne Power repugnant to the same,' and of an act of the Parliament of Ireland passed in the second year of the same queen's reign, (2 Eliz. c. 1, [1]) intituled 'An Act restoring to the Crown the ancient Jurisdiction of the State Ecclesiastical and Spiritual, and abolishing all Forborne Power repugnant to the same,' as makes it punishable to affirm, hold, stand with, set forth, maintain, or defend, as therein is mentioned, the authority, pre-eminence, power, or jurisdiction, of any foreign, spiritual, or ecclesiastical, of any foreign prince, prelate, person, state, or potentate theretofore claimed, used, or usurped within this realm, or any dominion or country being within or under the dominion and authority of his said majesty's dominions, shall diligently and faithfully, having no lawful or reasonable excuse to be absent, endeavour themselves to resort to their parish church or chapel accustomed, or, upon reasonable let thereof, to some usual place where common prayer and such service of God shall be used in such time of let, upon every Sunday, and other days ordained and used to be held as holy days, and then and there to abide orderly and soberly during the time of common prayer, preaching, or other religious service of God there to be used and ministered, upon pain of punishment by the censure of the church, for the same affects persons dissenting from the worship or doctrine of the United Church of England and Ireland, and usually attending some place of worship other than the Established Church: provided always, that no poulney premises shall be used upon any person by reason of his so absenting himself as aforesaid. [Members of the United Church of England and Ireland are still liable to the censure of the church, if they do not attend the services; those who do not assist除外 from these censures if they usually attend some other place of worship. Members of the United Church of England and Ireland are however protected by this act against pecuniary penalties for non-attendance at church; and no person shall be excommunicated, or, upon reasonable let thereof, to some usual place where person or persons inhabiting and being within this realm, or any other the king's majesty's dominions, shall, after the said feast of All Saints, willingly and willingly hearing and being present at any one of the said services, or such services as the king's majesty by the administration of the sacraments, of making ministers in the churches, or of any other rites contained in the book annexed to this act, is mentioned and set forth in the said book, or that is contrary to the same, and every such person, or any of them, by the verdict of twelve men, or by his or her own confession, or otherwise, shall, for the first offence suffer imprisonment for six months, without ball or mainprize; and for the second offence, being like manner convicted and committed for this term, or any term, for one whole year; and for the third offence, in like manner, imprisonment during his or their lives.'

Also so much of the said act as enacts, 'that for the more knowledge to be given hereof, and better observation of this law, all and singular curates shall, upon every Sunday in each quarter of the year, during one whole year next following this foresaid feast of All Saints next coming, read this present act in the church at the time of the assembly, and likewise once in every year following, at the same time declaring unto the people, by the authority of the Scripture, how the mercy and goodness of God hath in all ages been shown to his people in their oppressions and extremities, and at the same time making and putting on record and in writing, such hearty and faithful prayers made to Almighty God, especially where people be gathered together with one mind and heart to offer up their hearts by their prayer as the best sacrifices which Christian men can make.'

Also so much of any act or acts of the parliament of Ireland as may have extended to Ireland the provisions of the said act of the fifth and sixth years of the reign of King Edward the Fifth, as far as the same is applicable to Ireland.
common prayer and such service of God as in such acts are
mentioned are used in such time of let, upon Sundays and
other days ordained and used to be kept as holy days, and to
be observed in the due time thereof during the said
reign of the common prayer, preaching, or other service of God
there used and ministered: [The penalties from which persons
are hereby relieved will appear by referring to Eliz. c. 1, § 7; S. c. 9;]
Also an act passed in the fifth year of the same queen's
regin (5 Eliz. c. 1), intituled 'An Act for the Assurance of the
Queen's Royal Power over all Estates and Subjects within Her
Dominion.'
Also an act passed in the thirteenth year of the same
queen's reign (13 Eliz. c. 2), intituled 'An Act against the
bringing in and putting in execution of Bulls, Writings, or
Instruments, and other superstitious Things from the See of
Rome,' so far only as the same imposes the penalties or punish-
ments therein mentioned; but it is hereby declared that
nothing in this enactment contained shall authorize or render it
lawful for any person or persons to import, bring in, or put
in execution within this realm any such bulls, writings, or
instruments, and that in all respects, save as to the said penal-
ties or punishments, the law shall continue the same as if this
enactment had not been made.
Also an act passed in the twenty-ninth year of the same
queen's reign (29 Eliz. c. 6), intituled 'An Act for the more
speedy and due Execution of certain Branches of the Statute
and other Laws of the Realm, during the Reign of His Majesties
Successors,' intituled 'An Act to retain the Queen's Majesty's
Subjects in their due Obedience.' [LAW, CRIMINAL,
P. C. S., p. 178.]
Also an act passed in the first year of the reign of King
James the First (1 Jac. I. c. 4), intituled 'An Act for the
protection of the Statutes against Jesuits, Seminary Priests,
Receivers,' &c. [PARENT AND CHILD, P. C.]
Also an act passed in the third year of the reign of the
said King James the First (3 Jac. I. c. 1, § 2 in part), intituled
'An Act for a public Thanksgiving to Almighty God every Year on the Fifth Day of November,' as enacts that on every day of that year, and such persons inhabiting this realm of England and the dominions of the same shall always upon
that day diligently and faithfully resort to the parish church or
church accustomed, or to some usual church or chapel where
the said morning prayer, preaching, or other service of God
shall be used, and then and there to abide orderly and soberly
during the time of the said prayers, preaching, or other
service of God there to be used and ministered.
Also an act passed in the said third year of the said
King James's reign (3 Jac. I. c. 4), intituled 'An act for the better
discovering and repressing of Popish Recusants.' [LAW,
CRIMINAL, P. C. S., p. 178.]
Also an act intituled tenth year of the same king's
regin (7 Jac. I. c. 6), intituled 'An Act for administering the
Oath of Allegiance, and Reformation of married Women
Recusants.'
Also so much of an act passed in the thirteenth and four-
teenth years of the reign of King Charles the Second (13 &
14 Car. II. c. 4, § 11), intituled 'An Act for the Uniformity of
Publick Prayers, and Administration of Sacraments, and other
Rites and Ceremonies, and for establishing the form of making,
ordaining, and consecrating Bishops, Priests, and Deacons
in the Church of England,' as makes any schoolmaster or other
person instructing or teaching youth in any private house or
family as a tutor or schoolmaster punishable for instructing or
teaching any youth as a tutor or schoolmaster before licence
obtained from his respective archbishop, bishop, or ordinary,
of the diocese, according to the laws and statutes of this realm,
and before such subscription and acknowledgment made as in
the said act is mentioned.
Also so much of the last-mentioned act whereby any act or
person teaching youth, being publicly punished for teaching
therein kept a force. [LAW, CRIMINAL, P. C. S., p. 179.] This
statute against teaching in a private house or family has long since
fallen into disuse, but the formal repeal of it is an admission of
the necessity of such a law in this day.
There is still the 7th c. of the Church [CONSTITUTIONS AND
CARDS, ECCLESIASTICAL, P. C. S.], which goes farther than the statute
of Char:. II., but this canon may be safely neglected by any
act that shall be touch in 'publie house.' The canon forbids only men from teaching without
licence or subscription. At that time of days women probably
did not teach.
Also so much of any act or acts of parliament whereby
the said parts of the said act of the thirteenth and fourteenth
years of the reign of King Charles the Second herein-before
repealed have been confirmed or incorporated in any other act
or acts of parliament.
Also so much of an act of the parliament of Ireland passed
in the seventeenth and eighteenth years of the reign of the
said King Charles (17 & 18 Car. II. c. 6, § 6, [L.], as requires
the oath of allegiance from all such schoolmasters of children
in youth in private houses or families as tutors or schoolmasters
should take the oath of allegiance and supremacy, and as makes
such schoolmasters or other persons punishable for so instruct-
ing or teaching youth before licence obtained from their
respective archbishop, bishop, or ordinary of the diocese,
and before such subscription and acknowledgment made as in
the said act is mentioned.
Also so much of an act passed in the thirteenth year of the
reign of the said King Charles (30 Car. II. st. 2, § 5 in part),
intituled 'An Act for the more effectual preserving the King's
Person and Government by disabling Papists from sitting in
either House of Parliament,' as enacts that 'every person now
or hereafter convicted of Popish recusancy who hereafter
shall, at any time after the said first day of December, come
advisedly in or remain in the presence of the king's majesty
or queen's majesty, or shall come into the court or house
where they or any of them reside, as well during the reign of
his present majesty (whose life God long preserve) as during
the reigns of any of his royal successors, kings or queens of
England, of his body, his heirs, or successors, shall be
sentenced to perpetual removal from the company of
ministers, and disabilities in this act mentioned or contained.'
Also an act of the parliament of Scotland passed in the
eight and ninth session of the first parliament of King
James the Second (11 & 12 W. III. c. 4, § 1), intituled 'An
Act for preventing the growth of Popery,' and all laws, sta-
tutes, and acts of parliament revived, ratified, and perpetually
confirmed by the said act of King William's first parliament,
except as to the form of the formula in such last-mentioned
act contained.
Also an act passed in the eleventh and twelfth years of the
reign of the said King William the Third (11 & 12 W. III.
c. 4), intituled 'An Act to prevent the growth of Popery.' [LAW,
CRIMINAL, P. C. S., p. 179; PARENT AND
CHILD, P. C.]
Also an act passed in the first year of the reign of Queen
Anne (1 Anne, st. 1, c. 30), intituled 'An Act to oblige Jews
to maintain and provide for their Protestant children.'
This statute empowered the Lord Chancellor, on complaint
being made to him, to order a Jewish parent to allow his Pro-
testant children a maintenance suitable to the fortune of the
parent. [PARENT AND CHILD, P. C.]
Also so much of an act of the parliament of Ireland passed
in the second year of the reign of the said Queen Anne (2
Anne, c. 2), intituled 'An Act for the further security of the
growth of Popery,' as enacts that 'if any person or persons
shall seduce, persuade, or pervert any person or persons pro-
fessing or that shall profess the Protestant religion, re-
ounce, forsake, or seduce the same from the Protestant
religion, or reconcile him or them to the Church of Rome,
then in such case every such person and persons so sed-
cing, as also every such Protestant and Protestants who
shall be so seduced, perceived, and reconciled to Popery,
shall for the said offences, being thereof lawfully convicted, incur
the danger and penalty of paupermire mentioned in the statute
of paupermire made in England in the sixteenth year of the
reign of King Richard the Second.'
Also so much of the said last-mentioned act of Queen
Anne (s. 3) as empowers the Court of Chancery to make such order
for the maintenance of Protestant children, as the said
parents, or any of them, and their assigns, are or may be
suitable to the degree and ability of such parents and to the
age of such child, and also for the portions of Protestant children
in the hands of the said parents, as the court shall see meet, and
to that child to whom such portions shall be given and
the ability of such parents, and as empowers the said court to
make such order for the educating in the Protestant religion
the children of Papists, where either the father or mother of
such child is dead, or where such child is not an infant
of ten years of such children, as to that court shall seem meet, and
in order thereto to limit and appoint where and in what man-
ner, and by whom, such children shall be educated (s. 4); and
as enacts that the father of literate children shall pay their
charges of such educator as shall be directed by the said
court.
And an act passed in the eleventh year of the reign of
King George the Second (2 Geo. II. c. 17), intituled 'An

Act for staving the Estates of Papists conforming to the Protestant Religion against Disabilities created by several Acts of Parliament relating to Papists; and for rendering more effectual the several Acts of Parliament made for investing in the two universities of Ireland, the effectual Grant of the Presentation of Benefices belonging to Papists, except so much of the said act as relates to any advozone, or right of presentation, collation, nomination, or donation of or to any benefices, or to the payment of the stipends or salaries, or to the continuance or otherwise of any grants, or to any grant or avoidance thereof, or any admission, institution, or induction to be made thereupon, but so as that the repeal of the said act shall not in anywise affect or prejudice any benefice, right, or faculty, or any lands, tenements, or hereditaments under and by virtue of the provisions of the said act at the time of such repeal.

Also so much of an act of the parliament of Ireland passed in the seventeenth and eighteenth years of the reign of King George the Third (17 & 18 Geo. III. c. 49, s. 5 ([I]), intitled "An Act for the Relief of His Majesty's Subjects of this Kingdom professing the Popish Religion," as enacted "that no maintenance or portion shall be granted to any child of a Popish parent, upon a bill filed against such parent pursuant to the aforesaid act of the second of Queen Anne, out of the personal property of such Papists, except out of such leases which they may hereafter take under the powers granted in this act."

Also so much of an act passed in the eighteenth year of the reign of King George the Third (18 Geo. III. c. 60, s. 5), intitled "An Act for the Relief of His Majesty's Subjects professing the Popish Religion from certain Penalties and Disabilities imposed on them by an Act made in the eleventh and twelfth years of King George the Second, intituled "An Act for the further securing the Growth of Popery," as enacted "that nothing in this act contained shall extend or be construed to extend to any Papish bishop, priest, Jesuit, or schoolmaster who shall not have taken and subscribed the above oath in the above words before he shall have been apprehended, or any prosecution commenced against him."

Also so much of an act of the parliament of Ireland passed in the twenty-third and twenty-fourth years of the reign of the said King George the Third (23 & 24 Geo. III. c. 58 ([I]), intitled "An Act for extending the Provisions of an Act passed in this Kingdom in the nineteenth and twentieth Years of His Majesty's Reign, intituled "An Act for naturalizing such foreign Merchants, Traders, Artificers, Artists, Manufactures, Workmen, Seamen, Farmers, and others, as shall settle in this Kingdom," as enacted "as excepts out of the benefit of that act persons professing the Jewish religion."

Also so much of an act passed in the thirty-first year of the reign of King George the Third (31 Geo. III. c. 92), intitled "An Act for the Relief of His Majesty's Subjects professing the Popish Religion by Law subject, as enacted (s. 12) "or the inhabitants of the Eastern Counties, or any other county or county, in the persons of any such persons, or of any person or persons, or of the persons and properties of such persons, as shall be assembled, or any person or persons hath any suit, benefit, or advantage to any person who shall, by preaching, teaching, or writing, deny or gainsay the oath of allegiance, abjuration, and declaration herein-before mentioned, and appointed to be taken as aforesaid, or the declarations or oaths therein contained, or any of them."

Also so much of the said last-mentioned act (s. 15) as provides and enacted, "that no schoolmaster professing the Roman Catholic religion shall receive into his school for education the child of any Protestant father." [Law, Criminal, P. C. S., p. 180.]

Also so much of the said last-mentioned act (s. 16) as provides and enacted, "that no Protestant communicant in the Roman Catholic religion shall be permitted to keep a school for the education of youth until his or her name and description as a Roman Catholic schoolmaster or schoolmistress shall have been registered with the principal of the national schools for the county or other division or place wherein such school shall be situate, by the clerk of the peace of the said county, who is hereby required to record such name and description accordingly upon such book, and to give a certificate thereof to such person as shall at any time demand the same, and no person offending in the premises shall receive any benefit of this act."

Also so much of an act of the parliament of Ireland passed in the thirty-third year of the reign of the said King George the Third (33 Geo. III. c. 21, s. 14 ([I]), intitled "An Act for the Relief of His Majesty's Papists or Roman Catholic Subjects of Ireland," as enacted "that no Papist or Roman Catholic, or person professing the Roman Catholic or Popish Religion, shall take any benefit by or under this act, unless he shall have first taken and subscribed the oath and declaration in the same form, as is now prescribed by an Act passed in the thirteenth and fourteenth years of his majesty's reign, intitled "An Act to enable His Majesty's Subjects, of whatever Persuasion, to testify their Allegiance and to be known one of His Majesty's Subjects, and to be enrolled on his Majesty's four Courts in Dublin, or at the General Sessions of the Peace, or at any Adjournment thereof, to be held for the County, City, or Borough wherein such Papist or Roman Catholic, or Person professing the Roman Catholic or Popish Religion, doth inhabit or dwell, or before the going Judges or Judges of Assize in the County wherein such Papist or Roman Catholic, or person professing the Roman Catholic or Papish Religion, doth inhabit and dwell, in open Court."

Also so much of an act passed in the said thirty-third year of the reign of the said King George the Third (33 Geo. III. c. 44), intitled "An Act for requiring a certain Form of Oath of Abjuration and Declaration from His Majesty's Subjects professing the Roman Catholic Religion in that Part of Great Britain called Scotland."

II. And be it enacted, that from and after the commencement of this act his majesty's subjects professing the Jewish religion, in respect to their schools, places for religious worship, education, and charitable purposes, and the property held therein, shall be subject to the same laws and regulations as Papists and other Dissenters; and it will enable any person to leave a legacy for the instruction of Jews in their religion, which up to the passing of this act could not be done. [Jaws, P. C., p. 128.]

III. Provided, that nothing in this act contained shall affect any action or suit actually pending or commenced, or any property now in litigation, discussion, or dispute, in any of his Majesty's courts of law or equity.

IV. That from and after the commencement of this act all laws now in force against the wilfully and maliciously or contumaciously disquieting or disturbing any meeting, assembly, or congregation of persons assembled for religious worship, permitted or authorized by any former act or acts of parliament, or the disturbing, molesting, or nuisance any preacher, teacher, or person officiating at such meeting, assembly, or congregation, or any person or persons thereat, shall apply respectively to all meetings, assemblies, or congregations whatsoever of persons lawfully assembled for religious worship, and the preachers, teachers, or persons officiating at such last-mentioned meetings, assemblies, or congregations, and the persons there assembled.

ROMAN EMPIRE, EASTERN DIVISION OF—frequently designated the Eastern Empire, Greek Empire, or Beaux Arts Empire, was the Roman Empire into which the division of the Roman Empire into two parts occurred at an earlier period than the epoch usually fixed, viz. the death of Theodosius the Great; and was the result of causes which had been long at work. The warlike pre-eminence of Italy had enabled the Romans to achieve the conquest of the various and distant provinces which constituted the Roman empire, and the vigour of their central government, and the practical wisdom which usually guided it, enabled them to consolidate these provinces under an effective control. The reality and unity of the Roman government for the first three centuries of the empire, form a remarkable contrast to the disorders and embarrassment of the Parthic war and the frequent attacks of the Parthians. The several provinces were never separated from each other and from the capital, and were not united under a single government, but all together formed a part of the whole empire. The division of the Roman empire into two parts occurred during the period mentioned, but they did not arise from attempts at separation or local independence, but from competition for the possession of the whole. Dismemberment was not thought of. These contests however shook the whole framework of the empire: and as Italy lost its pre-eminence in warlike energy and political skill; and the emperors, on whose personal qualities, from the wars that occupied them, headed their states, and who were the only source of authority, declined in the condition and spirit of the empire depended, arose from provincial rather than Italian families; the sentiment of unity was weakened, and Rome was no longer felt to be the real...
capital of the empire. Had the empire, however, been as-
sailed by any hostile power capable of affecting the
safety of the whole, a sense of the common danger might have sup-
plied an incentive to all, but enemies existed to contend with, and apprehended little injury from
those who assailed the other portions of the empire. The
Germanic confederations of the Alemanni and Franks [Aka-
marius, P.C.] might now have acted as an additional
upper Danubian frontier, but neither Greece, Syria, Egypt,
nor even the lower Danubian provinces were endangered by
them: the Gothic [Gorthis, P.C.] might over-run Maesa and
little thought of the Rhianian side of the Hellenon; while the revived Persian kingdom, under
the dynasty of the Sasanidians [Persia, P.C.], which threatened the subjugation of the East, was little regarded in
Asia Minor. This mutual independence of the ass-
ailing nations tended to promote the dissolution of the em-
pire by fixing the attention of its several parts on the enemies immediately opposed to them, and allowed neither leisure to
attend to nor sympathy to feel for others.

The direction in which the fracture was likely to take
place was indicated by the geographical and other circum-
stances of the empire. The principal extension of the empire
was from east to west: and the Romans were not enough of a
naval people to avail themselves fully of the facilities which
the Mediterranean Sea afforded for keeping up the connec-
tion between their more distant provinces. The military
command was exercised by the Emperor, and the
army was impracticable, rather than by water. Had the Halles-
con and the Boospor been wider, the separation would perhaps
have been made there; but the narrowness of those straits, the insufficiency of the adjacent Greek
population, so closely united the opposite shores, that the sepa-
ration of the European and Asiatic continents was of little
practical moment; and the place of the fracture was deter-
mined to that part of the empire where the communication
by land, narrowed between the shores of the Adriatic and the
nearer part of the Danubian frontier, was impeded by the
difficulties of traversing the Illyrian islands of the great
Alpine chain. South of the Mediterranean, or the
place of fracture was determined by the great Libyan desert
west of Egypt and of Cyrenaica.

Another circumstance which tended to determine the point
of separation was difference of language. Before the Roman
armies had crossed the Adriatic the Greek language had become
the language of literature and education in the countries to the
rest of that sea, and formed an important bond of union.
The native languages of the East remained in use as spoken
languages, and after the diffusion of Christianity some of them
(e.g. the Syriac and Coptic and Armenian) came into use as written
languages; but the prose, and, to a less extent, the
poetry of the Mediterranean, the Nile, and Egypt were
Greek. West of the Adriatic the Latin tongue acquired a
similar or even a greater supremacy: for it superseded, though
probably in no regular order of form, the Egyptian
dialects of the Coptic and Syriac languages in the
West and Spain and Italy in popular use, as well as for literary
purposes, and forms the basis of the modern languages of those
countries.

Some African provinces west of the Libyan desert pos-
sessed the warlike resources of the other parts of the empire
it is not unlikely that they would have formed a separate
portion, and thus have led to a threefold division. But neither
did their internal resources allow this, nor was the frontier of
the Atlas pressed by any foe so formidable as to require the
presence of an emperor in that part. The Moorish tribes of the
desert, however formidable as marauders, were important for
their military potentialities, e.g. Julius in the time of Diocletian, and Firmus and Hera-
drion in the reign of Honorius, to acquire independence in
Africa were soon put down; and the African provinces, until
their re-organization under Constantine, who subjected them in
subjection, except during a few brief intervals, to the sovereigns of the
West.

(A.D. 286.) The first emperor of the Eastern part of the
empire was Valentinianus, who, on appointing Maximian as his colleague, retained to himself
the government of the Eastern portion, which he held till his
abdication, A.D. 305. [Diocletianus, Caius Valentinianus,
P.C.; Flavius Maximianus, P.C.]

(305.) Valentinianus Maximianus flavus, usually known
as Galerius, who had, under Diocletian, governed the
Danubian Provinces, with the subordinate rank of Caesar,
succeeded that prince as Augustus in the East, and
reigned till A.D. 311. [Maximianus Galerius, P.C.]

(311.) Flavius Valerius Licinius and Maximinus Daza
or Daza Licinius and Maximus Valerius, who was nephew of
that emperor, or was otherwise related to him, was appointed
Caesar shortly after the abdication of Diocletian. Licinius
was appointed Augustus by Galerius, apparently without passing
the ceremony of elevation, A.D. 307; and Maxi-
min, offended at the elevation of another to a rank superior
to himself, assumed the title of Augustus also. But both however
appear to have concealed a sort of precedence to Galerius
during his reign. After the death of Galerius the two em-
perors divided the East between them, Maximian having the Asiatic provinces, and
Licinius the European. The West was meanwhile (A.D. 312)
reduced under the sole dominion of Constantius. In A.D. 313
Licinius, with the assistance of the weak and helpless Maxi-
mian, was defeated by his rival, poisoned himself at Turin. In A.D.
315 war broke out between Licinius, now sole Emperor of the
East, and Constantine, which ended in the defeat of the
former, who died nearly the whole of his European provinces to
the conqueror. After an interval of eight years, war was
renewed between them; and the defeat and capture of Lic-
inius (A.D. 324) reunited the whole empire under Con-
stantius. [Maximinus Daza, P.C.; Constantius, Flavius
Valerius, P.C.]

Family of Constantine.

(323.) CONSTANTIUS I. MAJOR, who reigned till his
death, A.D. 337. [Constantius, P.C.; Flavius Valerius, P.C.]

From him succeeding emperors seem to have taken in almost
every case the name of Flavius.

(327.) CONSTANTINUS I. In the division of the
domains of Constantine the Great among his three sons,
Constantius, the second son, had the East. He is known
as Constantius II., his grandfather, who was emperor of the
West [Constantius I. Chlorus, P.C.] being known as
Constantinus I. On the defeat of Magnentius, A.D. 353
[Magnentius, P.C.], the whole empire was reunited under
Constantius II., who died A.D. 361. [Constantius II.,
Flavius Valerius, P.C.]

(361.) JULIUS, Flavius Claudius, commonly known as
JULIUS THE APOTHEOSIS, nephew of Constantine the
Great by his half-brother Constantius, ruled the whole empire
for two years after Constantius. [Juliannus, Flavius Claudius, P.C.]

With Julian the family of Constantine ends.

(383.) JOVIANUS held the whole empire only three months.
[Joivianus, Flavius Claudius, P.C.]

(394.) VALENTINIANUS I., almost immediately on his
appointment to the empire, resigned the East to his brother
Valens. [Valentinianus I., Flavius, P.C.]

(394.) VALENS, emperor of the West, died in A.D. 378.
[Valens, Flavius, P.C.]

(378.) GRATIANUS, son of Valentinian I., succeeded
Valens in the East, but almost immediately resigned it to
his cousin Theodosius the Great, as a sop to keep the West, which he had held
from his father's death in A.D. 375. [Gratianus Augustus,
P.C.]

Theodosian Family.

(379.) Theodosius I., the Great, ruled the East during
the remainder of his life, during the last year of which he
acquired the West also, thus for the last time uniting the
whole empire under one supreme ruler. [Theodosii I.,
Flavius, P.C.]

(395.) ARCADIUS, the elder son of Theodosius, succeed-
ed his father in the East, and Honorius, the younger son, in
the West. [Arcadius, P.C.]

(408.) Arcadius, who reigned in the East, died in 408.
[Theodosius II., the Younger, son of Arcadius, succeeded
his father while yet in his childhood.]

(405.) FULGERTIA, daughter of Arcadius, succeeded her
brother Theodosius: she had devoted herself to a life of
religious celibacy, but upon her brother's death she chose as
her associate in the Eudokia, a Thracian, whose merit had
raised him from an humble station to high rank. She married
him under an agreement that she would remain a virgin.
She died before her husband.

(450.) MAMURRIUS may be classed with the Theodosian
family, his connection with which raised him to the empire.

Mamurrius, P.C. He died A.D. 457.

The history of the East during the eventful period (about
170 years) from the first division of the empire under Dios
The letter to the death of Marcellus has been gathered from many authors. Of the genealogy of the Roman Emperors, the preceding Augustus, and the succeeding Augustus, there have been contemporaries Lactantius [LACTANTIIUS, P. C.], or the author, whoever he was, of the book De Mortibus Principum Helvetica, Cod. 80. It relates chiefly or entirely to the reign of Honorius. The history of Zosimus, who lived apparently under Theodosius II., probably came down to his own time; but the extract portion extends only to a.d. 409. (ZOSIMUS, P. C.) This work has been gleaned from the Western Chroniclers, Marcellinus, Prosper of Aquitaine, Prosper Tyro, and Victor of Tours; from the poems of Claudian [CLAUDIANUS, P. C.]; and from the writings of the imperial, Julian, son of the Cæsar, of the emperors Theodores, Athanasius, Gregory Nazianzen, and Chrysostom. The History, after the time at which Eusebius closed his history, was written by Socrates [Socrates, P. C.], Sozomen, and Theodoret [SOZOMENUS, P. C.; THEODORETUS, P. C.], whose works extend from the time of Constantine to that of Theodosius II.; and by Evagrius [EVAQRIOUS, P. C.], whose work, designed as a sequel to those of the three writers just mentioned, comes down to near the close of the sixth century. These historians are valuable, not only from the importance of ecclesiastical affairs recorded in their time, but from the frequent notice of secular events. The history of the whole period is contained in the work of Gregory Nazianzen, and in the great work of Gibbon [GIBBON, E.], who marks the important changes in the European States, and in the Empire as well. The later Byzantine writers, who were of the time of Leo I. and Justinian, are, for the most part, valuable, having a great deal of biographical matter, and having written their history at a time when much was known of the events of the world.
acquisition of part of Armenia under Theodosius the Great, by
the western conquests of Belisarius and Narses, and by the ex-
ception of the Byzantine territory along the eastern and north-
ern coasts of the Euxine, the progress of which is not easy to
trace. Even after the loss of the northern part of Italy, the Eastern empire was
largely secure; it had been under the emperors who preceded
Justinian.

The principal historical authorities for the period from Leo the
Thracian to Phocas are Theophanes, Isidore, Zonaras, the
Chronicon Paschale, and the Byzantine history of Priscus. Certain
Malalas or Malalas, Michael Glycas, Joel, and the versifiers:
these several writers comprehend the whole period, with
the exception of Malalas, whose "Chronographia" ends
during the reign of Justin I. The works of Belisarius are related by Procopius, P. C.,
whose introductory chapters to his Bellum Vandalicum, Bellum Geticum or Gothicum, and Bellum Persicum, con-
tain some important notices of events previous to that
time. The Secret History (Historia Arcana) of Procopius
relates to the same period. Agathias relates the events
A.D. 553-558. The history of the Emperor Maurice (Historia Mauricius) is related by Theophylactus Simo-
catta; and the reign of Phocas is included in the work of
Nicophorus of Constantinople, De Rebus post Mauritius gratios.
The Ecclesiastical History of Surius, a contem-
porary of Malalas, continues the event of Nicophorus; of
that of Nicophorus Callisti, a writer of much later date, to
the accession of Heraclius. After the reign of Anastasius,
we lose the valuable assistance of Tillemont; but the whole
period is detailed in the works of Ducange, Gibbon, Smidson,
and Le Beau.

**Heraclian Dynasty.**

(610.) **Heraclius** was the son of Heraclius, governor
of Africa, dethroned Phocas and put him to death. His
reign was one of the most interesting and eventful in the
whole course of Byzantine history; and his character one of
the most striking and inexplicable. The middle part of it
was characterized by brilliant and successful warlike expedi-
tions, by which the empire was saved from impending ruin.
The earlier part was characterized by inroads, and the latter part by
saudity and carelessness. ([Heraclius, P. C. and F. C. S.] He reigned above thirty years.

(641.) **Constantius III.** or more fully **Flavius Hera-
clius Constantius, or Novus Constantius** was the son of
Heraclius, the first wife Eudocia Fabia. The name of
Constantius was given in the hope that he would renew
the glory of the great Constantine. He reigned only about three
months, being, as was suspected, poisoned by his step-mother
Marina. His second wife was a Tribune; she was an-
imous to make her son Heracleus (who had been, by his
father's will, made colleague with Constantine) sole occupant
of the throne.

(668.) **Heraclonas.** The death of Constantine III.
excited a revolt against the government of Martinus, who
ruled in the name of her son; and both she and Heracleonas
were compelled by Valentius or Valentine (who had forced
him to raise him to the title of Caesar) to admit Constantus, son
of Constantine III., to a share in the empire; and were soon
afterwards deposed, imprisoned, mutilated, and sent into exile,
where they died.

(641.) **Constantius II.** (Constant I., son of Constantine the
Great, had ruled the Western empire) was originally named
Heraclius. He ascended to the throne in his eleventh
year, and reigned for twenty-seven years. During the first few
years of this reign the government was virtually in the hands
of Valentine; but Constantius, when he attained to manhood,
unleashed considerable energy both in military and eccle-
siastical affairs. He was however violent and unfortunate:
her ascendency was so nearly drawn to the end of the
power of the Caliphate, were still further diminished by the
p. 217]; and his Italian dominions were shaken by religious troubles. His conquest of Egypt by his brother's
order (A.D. 661) made Constantius a prey to the horrors
of remorse. His palace at Constantinople became odious to
him; and this, combined perhaps with political reasons, led
him to leave the empire in 668, and the重任 of the
reign of the son of empire to Rome. The success of his
Italian warfare however made him give up this plan, and he
fixed his residence at Syracuse, where he was murdered, A.D. 668.

(668.) **Constantine IV. Pogonatus.** On the death of
the Eudamus, eldest son of Constant II., succeeded his
father. He had been left by his father governor of Con-
stantinople A.D. 668, and on the news of the assassina-
tion of Constantine his brother by a rebel or settler
ment along the eastern and northern coasts of the Euxine,
the progress of which is not easy to trace. Even after the loss
of the northern part of Italy, the Eastern empire was
largely secure; it had been under the emperors who preceded
Justinian.

The principal historical authorities for the period from Leo the
Thracian to Phocas are Theophanes, Isidore, Zonaras,
the Chronicon Paschale, Chronadrian, Chronadrian, Malalas or Malalas, Michael Glycas, Joel, and the versifiers:
these several writers comprehend the whole period, with
the exception of Malalas, whose "Chronographia" ends
during the reign of Justin I. The works of Belisarius are related by Procopius, P. C.,
whose introductory chapters to his Bellum Vandalicum, Bellum Geticum or Gothicum, and Bellum Persicum, con-
tain some important notices of events previous to that
time. The Secret History (Historia Arcana) of Procopius
relates to the same period. Agathias relates the events
A.D. 553-558. The history of the Emperor Maurice (Historia Mauricius) is related by Theophylactus Simo-
catta; and the reign of Phocas is included in the work of
Nicophorus of Constantinople, De Rebus post Mauritius gratios.
The Ecclesiastical History of Surius, a contem-
porary of Malalas, continues the event of Nicophorus; of
that of Nicophorus Callisti, a writer of much later date, to
the accession of Heraclius. After the reign of Anastasius,
we lose the valuable assistance of Tillemont; but the whole
period is detailed in the works of Ducange, Gibbon, Smidson,
and Le Beau.

**Heraclian Dynasty.**

(610.) **Heraclius** was the son of Heraclius, governor
of Africa, dethroned Phocas and put him to death. His
reign was one of the most interesting and eventful in the
whole course of Byzantine history; and his character one of
the most striking and inexplicable. The middle part of it
was characterized by brilliant and successful warlike expec-
tions, by which the empire was saved from impending ruin.
The earlier part was characterized by inroads, and the latter part by
saudity and carelessness. ([Heraclius, P. C. and F. C. S.] He reigned above thirty years.

(641.) **Constantius III.** or more fully **Flavius Hera-
clius Constantius, or Novus Constantius** was the son of
Heraclius, the first wife Eudocia Fabia. The name of
Constantius was given in the hope that he would renew
the glory of the great Constantine. He reigned only about three
months, being, as was suspected, poisoned by his step-mother
Marina. His second wife was a Tribune; she was an-
imous to make her son Heracleus (who had been, by his
father's will, made colleague with Constantine) sole occupant
of the throne.

(668.) **Heraclonas.** The death of Constantine III.
excited a revolt against the government of Martinus, who
ruled in the name of her son; and both she and Heracleonas
were compelled by Valentius or Valentine (who had forced
him to raise him to the title of Caesar) to admit Constantus, son
of Constantine III., to a share in the empire; and were soon
afterwards deposed, imprisoned, mutilated, and sent into exile,
where they died.

(641.) **Constantius II.** (Constant I., son of Constantine the
Great, had ruled the Western empire) was originally named
Heraclius. He ascended to the throne in his eleventh
year, and reigned for twenty-seven years. During the first few
years of this reign the government was virtually in the hands
of Valentine; but Constantius, when he attained to manhood,
unleashed considerable energy both in military and eccle-
siastical affairs. He was however violent and unfortunate:
her ascendency was so nearly drawn to the end of the
power of the Caliphate, were still further diminished by the
p. 217]; and his Italian dominions were shaken by religious troubles. His conquest of Egypt by his brother's
order (A.D. 661) made Constantius a prey to the horrors
of remorse. His palace at Constantinople became odious to
him; and this, combined perhaps with political reasons, led
him to leave the empire in 668, and the重任 of the
reign of the son of empire to Rome. The success of his
Italian warfare however made him give up this plan, and he
fixed his residence at Syracuse, where he was murdered, A.D. 668.
events which he relates. The Monothelite controversy is dis-
cussed largely by St. Maximus, one of the Greek fathers.

(711.) Philippicus Bardanes succeeded to the now vac-
ant throne. He patronized the Monothelites. His reign was short: he was deposed, blinded and imprisoned, A.D. 718, by Leo, son of Isaurian general, George Buraphus, who had rebelled in Asia Minor.

(712.) Anastasius II. (previously to his accession he was called Artemius) succeeded Philippicus. He patronized the orthodox faith. A profession to the Monothelites by the Isaurian general, Leo III., was anathematized A.D. 715 by the troparch he which he had sent to attack the Saracens in the port of Alexandria. [Anastasius II., P. C.]

(715.) Theophanes III. made some cessions of territory in Thrace to the Bulgarians. He was deposed (A.D. 718) by Leo, one of his officers, who commanded in Asia Minor. [Theophanes III., P. C.]

I. Byzantine dynasty.

(718.) Leo III., Isaurius, the Isaurian, had borne in early life the name of Conon: he was a native of Isauria in Asia Minor, from which circumstance he is known in history as Leo Isaurius, or the Isaurian. [Leo III., P. C.] He died A.D. 741, after a reign of twenty-three years.

(741.) Constantine V. surmamed Copronymus, because he was defied with the title of Caesar by Artabazes, an able and energetic prince; but his reign was characterized by varied success in the field, and by the religious troubles aroused by the Iconoclastic controversy. He is charged with every kind of treachery, and by some a detected impostor of the so-called orthodox party; but the Icono-
clasts, whom he favoured, revered him as a saint. The re-
volt of his brother-in-law Attacatas, or Attavases, or Arta-
catas, who at the commencement of his reign disputed the crown with him, and was apparently supported by the image-
worshiping party, was near proving fatal to him; but in the end (A.D. 745) he recovered Constantinople, which Attav-
catas had occupied, and deposed that usurper. Constantine died A.D. 775, and was succeeded by his son Leo.

(775.) Leo IV., surmamed Chazares, which name he de-
rived from his mother Irene, who was a daughter of the Czar Chazares, of the Volga. [Tzarae—Chazares, P. C., vol. xxiv. p. 73.] The reign of Leo was short, but was disturbed by the revolt of his brothers, who were exiled, and by hostilities with the Saracens, who were defeated. Leo died A.D. 780. [Leo IV., P. C.]

I. Byzantine dynasty.

(780.) Constantine VI., sometimes called Porphyro-
gerius, or more accurately Porphyrogennetos, which title is however usually appropriated to Constantine VII., son of Leo VI., succeeded his father, while yet a minor, under the guardianship of his mother Irene, an Athenian whose beauty and genius had captivated Leo. Her endeavours to prolong his minority became a source of irritation to the patriarch Photius, and he was accused of avarice, perjury, and blindness, if not of the death, of Constantine, A.D. 797.

(797.) Irene, widow of Leo IV., succeeded her son. A project is said to have been formed of reuniting the Eastern and Western Churches, by marriage of Irene to Charlemagne of the Volga. the Vota Imperatorum Recensiorum of Georgius Monachus, and in the Regia of Generis: the continuator of Theophanes and the writers subsequently enumerated, all commence their histories with the reign of Leo V., at the point where Theophanes ceases.

 Macedonian Dynasty.

(867.) Basilii I. Maced, or the Macedonians, an extraordinary man, the son of a small landowner in Macedonia or Thrace, rose to the low condition of slave among the Bulgarians, by whom in his youth he had been carried captive, to the possession of the Byzantine throne, by becoming the colleague of Michael III., whom he soon after murdered. He subjugated the world to a warlike sect, which, for a long persecution, had driven into revolt, and recovered a considerable part of Asia Minor and the south of Italy and Sicily from the Saracens, who had conquered them. He died a.d. 886, and was succeeded by his son Leo. [Basilii the Macedonian, P. C.]

(886.) Leo VI., named Philosopher, the Philosopher, or Sapientes, the Wise, was engaged in wars with the Bulgarians in the north, and in the south with the Arabs, who attempted to recover Sicily; but his wars were on the whole unfortunate. He died a.d. 911, and was succeeded by his son Constantine. He was the author of various works, the chief of which were noticed elsewhere. [Leo VI., P. C. and Romanus II.]

(911.) Constantinus VII. Porphyrogennetos, or Porphyrogenitus, succeeded his father while yet a child of six years. He had for his first colleague (in which Nicaea, the seat of Basilii I., next in order of birth to Leo VI. He died after a reign of a year a.d. 912. The next colleague of Constantine was

(919.) Romanus I., named Lecapenus or Lacapenus (Benedict), was assumed a.d. 919, and successively raised his three sons, Christophorus in a.d. 919, and Stephanus, and Constantine VIII., in a.d. 928, to the title at least of emperor. Romanus engaged in the suppression of the abbeys and in Constantinople VII. only the title of emperor, compelling him to pass his time in retirement, in which he became distinguished by his literary and other accomplishments. But in a.d. 944 Constantine VIII. had recovered the possession of Asia Minor. He died in his prime, a man of measure, but somewhat infirm of body. He was a man of considerable importance [Byzantine Historiciens, P. C.] and include: 1. The life of his grand-father Basil the Macedonian, incorporated in the Continuation of the Chronographia of Michael the Cornutus. 2. The. Homilies. 3. The description of the themes or military provinces of the empire. 4. De Administrando Imperio, 'On the administration of the Empire,' written for the instruction of Romanus and successors of Constantine [says Dr. Plummer in Dr. Smith's Dictionary of Greek and Roman Biography] abundance of geographical, historical, ethnographical, and political facts of great importance; and without it our knowledge of the times of the author, and the nations which were either subject or his neighbours, would be little more than vagueness, error, or complete darkness. 5. De sermoneibus Byzantinorum,'On the Ceremonies of the Byzantine Court,' a detailed account of the observances of royalty and administration at that time. We owe also to Constantine various valuable Collectanea or compilations, especially De Legationibus, on the Embassies of the Romans to other nations and of other nations to them; which contains numerous valuable Excerpta from Polybius and other history-books. Many of these Collected works are for continental medicine and on agriculture. [Geoponika, P. C.]

(959.) Romanus II. [Romanus II., P. C.] distinguished as Junior, the Younger, sometimes as Fixus, the Boy, reigned only a short time, a.d. 963 of poison administered to him by his wife Theophano.

(963.) Basilii II. and Constantine IX., or as some call him (not recognizing the son of Romanus Lecapenus) called the Colleoni the Younger, aged respectively nine and two years, were nominally the successors of their father Romanus II.; but their predilect mother and guardian Theophano married Nicephorus, a valiant and successful general, and raised him, nominally to a share, but actually to the sole possession of the empire.

(963.) Nicephorus II. Phocas exhibited as a sovereign the same military skill and valour which he had previously shown. At the end of a.d. 967, he repaired to the scene of warfare; in the east he was successful: Cilicia and the north of Syria, with the strong cities of Tarsus, Antioch, and Aleppo, were recovered; and even Mesopotamia was invaded. To the west he was less signal and complete: he could only dispute with the Saracens and with the Western Emperor (to the possession of the southern extremity of Italy and of the island of Sicily. But wars against the Bulgarians, already conquered by Nicephorus made him unpopular, and the infamous Theophano, who was weary of him, conspired with her paramour Johannes or John Zimisces to assassinate him. He was murdered a.d. 969.

(969.) Johannes I. Zimiskes or Timiskes (969-976) succeeded to the sovereignty of Nicephorus; and, like Flus, was distinguished by warlike pre-eminence, both as a subject and an emperor. One of his first acts was to bring the guilty Theophano. A rebellion, raised by Bards Phocas, was soon suppressed; and Johannes was equally successful against foreign foes. He defeated the Russians, who had nearly conquered Bulgaria, and restored the Bulgarian king to his throne, but in subordination to the empire: he recovered to the empire, though only for a short time, its long lost possessions in Mesopotamia, and extended the conquests of Nicephorus to the Adriatic. The Lombard king's career was cut short by poison administered by some of his own courtiers, after a reign of only six years.

From a.d. 975 begins the actual reign of Basil II. [Basilii II.], or the Imperial period. He exercised the full sovereign power, and of his brother Constantine; but the youth of Constantine in the first instance, and afterwards his luxurious indulgence and carelessness, left the government to the able and energetic regency of Basil. Indeed, when the inevitable death of Bards Sclerus, was with much difficulty suppressed, and the conquest of Byzantine Italy and Sicily by Otho or the Saracens was prevented chiefly by their wars with each other, the regency which we have described as the regency of P. C. Constantine was in reality a struggle for the possession of those countries. His martial prowess retained the conquests of his predecessors in Syria, despite of the efforts of the adjacent Saracen powers. By the complete overthrow of the Bulgarian kingdom he restored the long lost frontier of the lower Danube, as far up as Sirmium: he defeated the Caucasian mountaineers and protected the Byzantine part of Armenia from invasion: and he was preparing for the complete conquest of Sicily and Byzantion Italy when he died a.d. 1025. Constantine survived his brother only three years; and his death a.d. 1028 cleared the way for a commonly reputed potentiate, the dynasty of the Palaeologus. (though it continued in the female line still longer) the supremacy of which was of longer duration than that of any other Imperial dynasty, except the closing one of the Palaeologus.

The Macedonian period of a hundred and sixty years was one of apparent, if not of real revival. The frontiers of the empire had been extended in the north from the defiles of Mount Imaena to the bank of the Danube, and in the south from the range of the Taurus to the heights of Lebanon and the banks of the Euphrates and even of the Tigris. The throne had been occupied by several warlike princes, and the decay of the royal powers, the Caliphate [Caliph, P. C.] and the Bulgarian kingdom, rendered their prowess effectual for the revival of Byzantine greatness. The literary taste and acquisitions of Leo VI. and Constantine VII. led to a revival of literature; and several valuable writers belong to this period. The history of this area is contained in Zonaras [Zonaras, Joanna, P. C.], Cedrenus, Glycas, Ephræmium, and Constantinus Manasses; the anonymous Chronicle of Gerard of Thessalonica, the Historia Arabica, the Chronicle of John Skylitzes (sometimes called, but on insufficient ground, Leonicus), Symeon Magister, Georgius Monachus, Leo Grammaticus, and Genesius. Of these authorities Genesius ends with the death of Basil II. in a.d. 1025; Leo Grammaticus, with the death of Romanus I. Lecapenus (a.d. 948 or 949), a few years after his deposition; and the continuator of Theophanes and Symeon Magister, with the early part of the reign of Nicephorus Phocas, and the life of Ioannes Zimisces, who lived in the reign of Basil II., and whose history comprehends the reigns of Romanus II., Nicephorus Phocas, and Johannes Zimisces (a.d. 959-975). [Byzantine His-
Hundred half. He Theodora, Comnena. Romans, after a short reign. in which his troops were defeated by the Turks, and in which he was assassinated by his wife and her paramour Michael, when she elevated to the throne. [Romanus III., P. C.] (1034.) Michael IV. Filippagos, the Filiopagian, reigned meanly and miserably for more than seven years and a half. (1041.) Michael V. Calaphates or Calaphatta (i.e. a reformer of vessels), a name derived from the occupation of his father, Manuel, who, in 1028, had married Zoe. But the people of Constantinople, inspired with indignation at this punishment inflicted on one of her high birth, insisted on her recall, and on the release of her sister Theodore from the monastery in which she had been placed, and deposed Michael, depriving him of his eyes, after he had reigned little more than a year. (1042.) Zoe and Theodore reigned jointly for a few months, when Zoe married and raised to partnership in the empire. (1042.) Constantine X., or as some reckon Constantine IX., succeeded, from his vault, Mornachus, the Bishop Comnena. This emperor had to represent a revolt in Cyprus; to contend with the Turks on land and sea, and to defend his throne from his rival, Georgius Manasses, the greatest of the Byzantine warriors of his day, who being driven by injustice to revolt, advanced against Constantinople and defeated the imperial forces, fell, probably by assassination, in the moment of victory. Another rebel, Leo Tornicius, a relative of the emperor, was defeated by Constantine, who also vanquished a Russian fleet which threatened Constantine X. and his people, and also the limits of the empire in the East by incorporating the territory of a subordinate chieftain of Armenia and Iberia who had revolted and was subdued. Zoe died a.d. 1050 and Constantine a.d. 1054. Theodore was thus left sole inheritor of the sovereignty. She had previously refused to marry; but toward the close of her short reign, she consented, on her death-bed, to a nominal union with an armed warrior named Michael. (1056.) Michael VI. Stratocrates, thus succeeded to the empire, which he held for about a year, when he was deposed. Theodore had died a few days after their marriage. The short reign of Michael VI. was troubled by the unsuccessful revolt of Theodoreus, a cousin of the late emperor Constantine X. (1057.) Isaacus I. Comnenus, whose successful revolt had deposed Michael VI., was reigning about a year after his death, induced by his failing health to resign the empire. The succession was offered first to Johnnes Comnenus, the Emperor's brother, who declined it; and then to Constantine Ducas. (1069.) Constantine XI. (or X.), succeeded Ducas reigned seven years, in which the empire was assailed by the Hungarians and other enemies on the side of the Danube. On his death the throne was occupied by his son Constantine, who was soon induced by his failing health to resign the throne. The succession was offered first to Johnnes Comnenus, the Emperor's brother, who declined it; and then to Constantine Ducas. (1069.) Michael VII. Stratocrates, valiantly opposed the progress of the Turks, who were in force in Asia Minor, but his efforts resulted in his defeat and captivity (a.d. 1071). [Seleucides, P. C.] On his release, he attempted to recover his throne, but was defeated, taken prisoner, and deprived of his eyes with such cruelty, that he died a few days after. [Romanus IV., P.C.] Eudocia had, during the interval of his imprisonment, renewed her suitor Michael VII. then assumed the exercise of the sovereign power: but by his cowardice he incurred the contempt of his subjects, and he was, with his brothers, deposed by the rebel Niketas Botaniotes, who, as the representative of the deceased emperor, had succeeded to the throne of the family of Ducas with Michael VII. It occupied the Byzantine throne less than twenty years. (1072.) Nicholas III. Botaniotes [Nicaeophilos III., P. C.] had revolted against Michael at the same time as his namesake. Alexius Comnenus, the general of Botaniotes, defeated Bryennius, and compelled him to surrender, but shortly afterwards revolted in his own account, and assumed (a.d. 1081) in defence of Botaniotes and acquiring possession of the throne. He was the nephew of the Emperor Isaac I., and son of that Joannes or John Comnenus who, on the death of his father, had ascended the crown. The accession of Alexius was the commencement of the permanent sway of the Comnenian family or dynasty. The century and a half which elapsed from the close, at least in the middle of the eleventh century, and the accession of the Comnenian, was a period of disaster and decline. The various domestic revolutions, several of them accompanied by bloody civil wars, have been noticed. In the first place, the Normans took the first vision in 1071, and the second, in 1078, by the Saracens, driven to the Byzantine city of Bari, as mercenary soldiers, had gradually conquered, between a.d. 1040 and 1080, the Byzantine portions of Italy and Sicily, the last relics of the conquests of Belisarius and the other generals of Justinian. In the East, the Turks, under their sovereigns of the Seljukian dynasty [Seljukides, P. C.; Turkes, Turks, P. C.], conquered the Caucasian and Armenian provinces of the empire, and either before or very soon after the accession of Alexius, succeeded in establishing in Asia Minor a kingdom which the capital was fixed at Nicea, or Nicé, in Bithynia, about a hundred miles to the north of Constantinople. The disasters of the period were augmented by the increasing bitterness and the complete separation of the Greek and Latin churches [Greek Church, P. C.], which weakened the Byzantine army. The small degree of the recovery, the incursions of the Turks, and the West of Europe; and led the latter to regard with comparative indifference the threatening progress of revived Mohammedanism under the protection of the Turkish power. For the history of the persons we have still the chronicles already enumerated; but Cedrenus ends with the year 1058, and Constantine Manasses with a.d. 1081. To these we may add Joannes Scylitzes Cypriotes, the fragments of whose history refer to the period from a.d. 1094 to 1078; Nicophorus Bryennius (not the Emperor so called, but the son-in-law of Alexius Comnenus), whose Commentarii give the history of Alexius before his accession to the empire; and Anna Comnenus, daughter of Alexius, and wife of this Nicophorus Bryennius, who has in her Alexia* given the history of her father's life. Comnenian Dynasty. (1081.) Alexius of Alexius I. Comnenus. The commencement of the long reign of this prince was unfortunate: the Turks pursued their conquests on the east, and the Normans, taking Adrianople, invaded the empire. The facility of the Turks was however repelled, and that of the Normans diverted by the first Crusade. and Alexius, following in the wake of the Crusaders, recovered possession of Asia Minor, with the exception of the inland and mountainous districts. He died a.d. 1118. [Alexius Comnenus I., P. C.; Crusades, P. C.] (1118.) Joannes II. Comnenus, or as he is commonly termed Calo-Joannes. Eudocia* son-in-law of Alexius, given him account of his diminutive stature and homely features, succeeded his father Alexius. His eminent virtues rendered his reign one of the most truly glorious in the Byzantine annals. He repelled the hostile attempts of the Hungarians and others on the Danube, and of the Turks in Asia. A rain attempt to dispose him of the throne at the commencement of his reign was made by his accomplished but ambitious sister Anna Comnena and her husband Nicophorus Bryennius. [Anna Comnena, P. C.] Joannes II. died of a wound received while hunting. a.d. 1143, just as he was on the point of attempting to subjugate the Latin States founded by the Crusaders in Syria and Asia Minor, and the conquest of Asia. Manuel I. Komnenus, born, in character, a singular resemblance to our own Richard I. He continued the warlike exertions which his father had made, and against the same enemies: but in an interval of a few years, a large part of the wealth and the empire, which had been accumulated during a century, was dissipated. He was succeeded on his death the throne of his father Manuel I. He was only ten years of age at his accession, and was under the guardianship of his mother Maria: but both mother and son were, in about three years, put to death by the hands of Manuel I., father of Isaac Comnenus, who was a younger son of Alexius I.
(1180.) ANDROMAICA I. CONNENIA then usurped the throne, but after a reign of two years was murdered by the people of Constantinople. [ANDROMAICA COMMENIA, F. C.] In him the male line of the Comneni ends. He was succeeded by Isaac Angelus, whom he attempted to put to death, and consequently he fled to Greece, beyond the borders of the empire. [1185.] ISAAC II. ANGELUS was descended from the youngest daughter of Alexius I. His contemptible reign was marked with the final loss of the Isle of Cyprus, usurped by a man of the imperial race, and the loss of Thessaly, which, indeed, was taken under Richard I. of England and given to Guy of Lusignian, the expelled King of Jerusalem; and of the territory between the Haemus and the Danube, which was lost by the revolt of the Bulgarians, under whom the Slavonic princes of which united themselves and their people to the Latin church. Isaac recovered, however, some parts of the European Albania and Epirus from the Normans of Italy and Sicily. Isaac was dethroned and blinded after a reign of ten years by his own brother, Alexius, who succeeded him.

(1185.) ALEXIUS OF ALEXIUS III. ANGELUS OF COMNENUS (which latter name he assumed), after an unfortunate reign in which he was defeated by the Turks in Asia Minor and by the Bulgarians and Comneni in Europe, was dethroned by Alexios, son of Isaac, who was assisted by the Crusaders of the Fourth Crusade.

(1203.) ISAAC II., the deposed and blinded emperor, and his son ALEXIUS OF ALEXIUS IV. ANGELUS, were, in consequence of this revolution, placed on the throne; but a revolt of the people, excited by Alexios, drove them from the capital and to the position and to the extinction of Alexius IV., whom Isaac II. soon followed to the grave. The branch family of the Angelis, and indeed the dynasty of the Comneni, and the hopes of the universe, were now extinguished.

(1204.) ALEXIUS OF ALEXIUS V. Ducas, surnamed Murzilli, is, of the SHAGGY EYEBROWS, the successful revolter, succeeded to the throne (which a shadow of an emperor, Nicholas Comnenus, had for an instant occupied), but was at once besieged, and after a few months taken prisoner or put to death by the Crusaders, who captured Constantinople, divided a considerable part of the conquered territory into several Latin principalities, and established a line of Latin princes on the throne of the Eastern Empire. [BALDWIN I., EMPEROR OF CONSTANTINOPLE, F. C.; DANDELO, EMIRIO, F. C.]

The period from the accession of Alexius I. to the capture of Constantinople by the Latins is one of great vicissitudes. Alexius I. found the empire reduced in limits and exhausted in resources; but his dexterity in availing himself of the results of the first crusade, and the ability and valour of his successors John the Second and Manuel I. extended the limits of the empire without materially increasing its strength. From the death of Manuel we have a period of rapid conquest, but a period of decline, the Seljuk Turks, the Scandinavians, and the crusaders, grinding down the empire, by covering a considerable part of what they had lost in Asia Minor; until the empire was limited to Thrace, Macedonia, Epirus, Greece, and its islands (of which, however, Crete was lost by Manuel in 1204), and the eastern portion of Asia Minor, especially on the coast. This diminished territory a considerable part fell with the capital into the hands of the Latins. Of that part which escaped their power, the eastern coast of the Euxine was appropriated to form the new Greek empire of Trebizond or 'Asia Minor' (TREBIZOND, EMPIRE OF, F. C.); and two other fragments were detached in the west to form the despots of Epirus and Thessaly, the formation of which, though sometimes referred to by the partisans of the Fourth Crusade, was never again incorporated with it. [ALBANIA, F. C.]

The remainder of the independent portion of the Greek empire, the rulers of which assumed the title of emperor, was divided into the petty states of Nicea, or Nice, in Asia Minor, and afterward recovered Constantinople, will be regarded as the connecting link between the overthrown and the restored Greek empire. All the transactions of the year 1204 are included in the history of the empire of Trebizond, the sequel of which, though sometimes referred to by the partisans of the Fourth Crusade, was never again incorporated with the empire of Trebizond.

The history of Alexius I. is contained in Eparnes and Gyraena; both of whom conclude their Annals with his death, in the short life of Joel, in the Journal of Eastern History, and in the Pantheon of Eparnes, which becomes from his reign now more fall and important; and especially in the Alexian of his daughter Anna Comnenus. [ANNA COMNENUS, F. C.] The history of the empire of Trebizond is narrated by the Alexian of Anna Comnenus, whom the latter ends with a.d. 1204; and in the histories of Cinnamus, which comprehends the reign of John III. and nearly the whole of that of Manuel I.; and of Nicetas Atticamitas, or Nicetas Chondrias, which extends from the death of Alexius I. to the death of Baldwin I., first Latin emperor, A.D. 1208. The Latin authorities, Galliemus Tyrrenus (William of Tyre), and the others contained in the Gesta Dei per Francos, or Chronicles of France, probably in the hands of the pope, at the time of the collection, are enumerated in Michaud's Bibliographie des Chroniques. [CRUSADES, F. C.]

(1180.) BALDWIN I. [BALDWIN I. F. C.], Count of Flanders and Hainault, was appointed Emperor by the victorious Crusaders, but was, after a year's reign, captured in battle by the revolted population of Thuroe and the Bulgarians in the Via Graecorum, and died a.d. 1182. [Baldwin I., EMPEROR OF CONSTANTINOPLE, F. C.]

(1219.) PETRUS DE COUTEIET, PETER OF COUTEY, Count of Auvergne, ascended the throne in conjunction with and in the right of his wife ISLANDIS OF YOLANDA, sister of Baldwin and Henry. He never assumed the title of emperor, but was taken prisoner on his way thither by the despots of Epirus, and died in captivity a.d. 1219. Yolanda died soon after. [1219, or, according to others, 1221.] ROBERTS, or ROBERT C., son of Peter of Courtenay, succeeded to the throne. He was, some time after, expelled by his own subjects, and died a.d. 1228. [Baldwin II., EMPEROR OF CONSTANTINOPLE, F. C.]

(1219.) ISAAC II. ANGELUS OF COMNENUS, F. C.]

The Greek emperors will be noticed when speaking of the authorities for the contemporary Greek emperors of Nice.

Greek Emperors of Nice or Nice.

(1204.) THEODORUS II. LASCARIS [THEODORUS LASCARIS, F. C.], in an active reign of eighteen years, re-established the Eastern Empire in a portion of its ancient Asiatic territory, of which Nice was made the capital. He had married Anna, daughter of Alexius III. Angelus or Comnenus.

(1229.) IOANNES III. DUCAS VATATZES succeeded Theodore Lascaris by virtue of his marriage with Irene, daughter of Theodore Lascaris, or rather by his merit, which induced him to assume the crown. He reigned for nearly thirty years, and extended his dominions, and ruled for another forty years, and recovered a portion of territory from the Greek empire of Trebizond. He died a.d. 1255. [THEODORUS II. LASCARIS, SON OF JOHN III., SUCCEEDED his father, and died after a reign of four years.]

(1259.) IOANNES IV. LASCARIS, a minor, son of Theodore II., succeeded, but he was soon virtually and afterwards openly deposed, and then blinded by Michael Palaeologus, first emperor of the family of the Palaeologoi, and first of the restored Greek emperors of Constantinople.

The historians of this period are Georgius Acropolita, whose history just comprehends the period when the seat of the empire passed to Nice (a.d. 1204); Nicetas Gregoras, whose history begins at the same point but comes down later than that of Acropolita; and the Metrical Chronicle of Ephraemius, which ends with the recapture of Constantinople a.d. 1261. The history of Nicetas Gregoras contains only a year or two after the capture of Constantinople by the Latins. [RESTITUTION OF THE WESTERN EMPIRE OR GREEK EMPIRE TO CONSTANTINOPLE, F. C.]

(1905.) MICHAEL VIII., PALAEOLOGUS, or more fully PALAEOLOGUS COMMENOS, great-grandson, through his mother, of Alexius III. Comnenus, and by the death of his uncle, boy Emperor Ioannes IV. In 1261 Constantinople was recovered by Alexius Stratzycopulos, and Michael restored the
seat of government to that city. But if the Latins were expelled, the empire never recovered the extent which it had before the Latin conquest. It had been dismembered on the east and west by the empire of Trebizond and the despotate of Epirus; though the despot of Epirus had, in the reign of Joannes Vatatzes, recognised that princes as his lord paramount, personally and in person, and usually warred under his command. His power threatened the supremacy of the Latin emperors, and encouraged the Venetians, Pisans, and other Latins engaged in commerce or manufactures to remain at Constantinople, or in the suburbs, and established a Genoese colony in the suburb of Galata. His guilt in blinding and exiling his unhappy compatriot Joannes was punished by Arsenius, patriarch of Constantinople, with excommunication; and the retaliatory measure of the deposition of Arsenius led to serious schism in the church of nearly fifty years' duration. A hypothetical union with the Latin church, ratified at the Council of Lyon, A.D. 1274, augmented the religious troubles of the Greeks, though it averted the threatened attempts to reconquer the Latin throne of Constantinople. Michael died A.D. 1283.

(1283.) ANDRONICUS III. PALAEOLOGUS, or more fully DUXIS COMMINUS ANGELOS PALAEOLOGUS, distinguished as the Younger, after the death of his father Michael VIII. and reversing the policy which Michael had pursued, dissolved the hollow union of the churches and was excommunicated by the Pope (A.D. 1287). His reign was marked by the establishment in Asia Minor (about A.D. 1300) of the rising monarchy of the Osmanli, or Ottoman Turks, so called from Othman their founder, in place of the declining kingdom of the Seljuks, which had fallen overthrown by the Crusaders in the thirteenth century to the alliance than by Latin aid. Ananias Palaeologus succeeded to the empire the whole of the Moors. He died A.D. 1425.

(1425.) JOANNE VII. PALAEOLOGUS, surnamed PORSYHOGENETES or PORFYRIONGENES sometimes called Joannes Palaeologus II., succeeded his father Manuel, and followed the same policy of seeking aid from the west, to conciliate which he brought about the hollow union of the Greek and Latin churches at the council of Florence, A.D. 1439, to be present at which, he visited Italy. He ruled personally in Constantinople; the fragments of the empire in the Moors and in the Tauric Chersonesus, the Crimans, were ruled by his brothers as vassals. His reign precipitated the downfall of the empire at the end of the fourteenth century. The Greek church disgraced his subjects; the allies secured by it were defeated by the Turks at Vatra A.D. 1444 (MURAD II., P.C.), and the Turks attacked the Moors and allowed its ruler, Usman, the brother of Sultan Murad, to pay the condition of paying tribute. Joannes VII. died A.D. 1448.

(1448.) CONSTANTINE XIII. (some call him XI.) PALAEOLOGUS, surnamed Dragasek, last emperor of the East, succeeded his brother John Palaeologus (1342-1444; 1448) in three sessions in the Moors to his brothers Demetrios and Thomas. His brief reign was ended by the capture of Constantinople by the Turkish Sultan Mahomet II. A.D. 1453. Constantin fell bravely in the defence of his capital; and the empire of the East fell with him: its dismembered portions were subdued by the ambitious and powerful Mahomet a few years after, except such as were occupied by the stronger hand of the Latin. Demetrios and Thomas Palaeologus were expelled from the Moors in or soon after A.D. 1449; the empire of Trebizond was extinguished in A.D. 1464, and all the value of Chersonese [Scandza-Bog, P.C.], who died a fugitive in A.D. 1467, which was, did not prove the final subjugation of Epirus. [MAHOMET II. P.C.]

Thus were extinguished the name and the last remains of the Palaeologae. From its reputed foundation by Romulus it had subsisted for twenty-two centuries; from the settlement of the empire by Augustus nearly fifteen centuries; a duration as yet unequalled in the history of the world, unless it be in China. From the account of these emperors and their times, the first Constantin to the capture of the city of the time of the last Constantine, that magnificent city was never in the possession of an enemy except during the half century of Latin occupation. The declarations of Pope Pius II. that papal power was hardly interrupted though the seat of empire was temporarily fixed at Nice. The despotical character
of the government; if it prevented the growth of that national spirit and character which really constitute the strength and prosperity of a nation, yet prevented the dissolution of the empire, which presents amidst frequent disasters a remarkable cohesiveness and unity, until the Latin conquest in A.D. 1204. But as from the same deep-seated conviction of the necessity of the recovery generally fell short of its predecessors. During the temporary fluctuation of the condition of the empire, the tide of its greatness and prosperity was gradually ebbing. The spirit of the time was not destitute of the characters of the extent of the empire both in the east and west. Justinian recovered only a portion of the latter. Heraclius saved the empire from extinction at the hands of the Persians, and effectively crushed their power; but he did not recover what had been taken by the Lombards in the west, and Africa and Palestine, which were wrested from his successors by the Saracens, were never recovered. The revival effected in the Macedonian period by Basil I., Nicephorus, John Tzimisces, and Basil II., fell short of that of Heraclius; and that of the earlier Comneni fell short of the success of the Macedonian princes. The history of Lazars and the Varmados never made a fragment of the empire of the Comneni, grew less and less until its extinction by the Turks. Yet this fragment preserved the name of the 'Roman Empire,' which it has transmitted to modern day. Byzantium (or Constantinople) was the Roman in Europe, the last seat of the Byzantine Empire (Bumill-i, P. C.), and Rome or Ruma, in Asia Minor, the seat of the empire of Trebizond.

Of the last period of the empire is contained in the 'Roman History,' or rather 'Romaic History,' of Nicephorus Gregoras (from A.D. 1204 to 1351); in the history of the emperors (from Michael Palaeologus to Andronicus the elder), by George Phocas (1369) by George Pamphilius; of the Emperor Johannes Cantacuzenus, containing the account of his own time; in the 'Historia Byzantina' of Ducau, especially including the reigns of the two Johns, V. and VI., and their brothers, to 1462; in the 'Geschichte der Georgii Phocas or Phrantas, from the recovery of Constantine in 1261 to A.D. 1477; and in the History of the Turks by Laoncous Chalcedonidales. We do not mention the contemporary Latin historians whose works include notices of Byzantine history; and much of the recent historians we shall only mention Ducange, Le Beau, with his continuator Amelin, and Gibbon. Much valuable information is contained in the articles on the Byzantine Emperors and other eminent personages connected with the Eastern Empire, chiefly written by Dr. Plate in Dr. Smith's Dictionary of Greek and Roman Emperors, and of his Decline and Empire, with all its admirable qualities, is unsatisfactory as a history of the Eastern Empire. The unity which he has given to his episodes has destroyed that of his main subject; and his readers feel the different parts of his composition, and the various portions which constitute the history of a reign or period. The empire itself is forgotten while we follow his absorbing narratives of the migrations of the Huns, the conquests of the Saracens or Moguls, and the vicissitudes of the Crusades; and the Byzantine history, interesting and important as it is, is yet to be written in a form suitable for the English reader.

ROMANELLI, GIOVANNI FRANCESCO, was born at Viterbo in 1617. He studied a short time with Demenichino, but he is chiefly known as the scholar of Pietro da Cortona; and he was one of the principal hangers on of Borghese, who has inherited a name as a rival to Carlo Maratta and the school of Sacchi; and even to Pietro Cortona himself. Romanelli's picture of the Deposition, in the church of Sant Ambrogio della Scala, is a testament of those good qualities with which his associates in the school. Romanelli showed more delicacy of execution, but considerably less power than Cortona. There is a Presentation in the Tempio in one of the chapels of St. Peter's, which he might have been allowed to be done at the church of the Certo. He was twice in Paris with his patron Cardinal Barberini, and he died at Viterbo in 1663, when about to set out with his family upon a third visit to that capital. There is a large copy of Guido's Triumph of Bacchus at Hampton-Court, by Romanelli. (Pascoli, Vite de' Pittori &c. Moderni; Lanz, Storia Pittorica, &c.)

ROMBERG, ANDREAS and BERNHARD, cousins, were the eldest sons of brothers who enjoyed a considerable share of reputation as instrumental performers during the middle and latter part of the last century.

Andreas was born at Osnabruck in 1767; Bernhard in 1770. Both held appointments in the royal chapel of the Elector of Cologne, at Bonn, about the year 1790. The younger was distinguished by his superior performance on the violin; the latter as an almost unrivalled player on the violoncello; and both by their compositions, even at that early period of their career. The progress of the French armies at the commencement of the revolutionary war drove the two cousins to Hamburg, where their talents immediately procured them engagements. In 1795 they quitted that city, and visited many parts of Germany and Italy, establishing their reputation, wherever they presented themselves, as professors of the first class. They returned to Hamburg in 1797, where the elder remained; but the younger left that city two years after, and proceeded alone through England and Spain to Lisbon, where he was appointed an instructor in the royal chapel at Berlin. Andreas in the meantime turned his attention more exclusively to composition, and produced four operettas; he also set Schiller's 'Ode to Music.' For the church music of modern day, Roumelin (from Roumania) composed for four voices, and a 'Pater Noster' for three, besides many psalms. For the chamber or concert-room he composed much music, Schiller's 'Song of the Bell;' 'Das Lied von der Glocke;' he also wrote other things, which are now lost, in every part of Europe. He also produced two full operas, 'Die Grosmuth des Scipio;' ('The Magnanimity of Scipio'), and 'Die Rolinen von Paluzzi.' ('The Ruins of Paluzzi'). In his later part of life he published his 'Italian;' and, if an opinion of the work may be formed from a pianoforte arrangement, it seems to be an opera that might be successfully adapted to one of our musical theatres.

Bernard was perhaps less known in B or Annales, but his much instrumental music, particularly for the violoncello. Both cousins indeed were for a time chiefly known as authors by their compositions for their respective instruments. Their posthumous fame is mainly attributable to their symphonies and overtures, the best of which have become familiar to the amateurs of this country by the admirable performance of them at the concerts of the Philharmonic Society.

Andreas Romberg died in 1821, and leaving a family in embarrassed circumstances, a concert for their benefit was generously got up in London by the Philharmonic Society, which was attended by twenty thousand persons. Bernhard was one of the principal presiders. Bernhard had pointed one of the professors at the Conservatoire de Musique at Paris, in 1801, and created Chevalier of the Legion of Honour, but retired from the office two years after. He came to London in 1820, and died there in 1831, of consumption. He visited this country, and gave a concert, by which he was no longer so much the scholar, or the composer, or the pianoforte player as he was the composer of the 'Emperor,' and the violoncello part of the 'Incidental Music' of Rossini's 'William Tell.' He had composed a great many operas, oratorios, or sacrid pieces, and other works in every style of composition.
accession of the respective bishops or patriarchs, according to the generally received computation; but we may observe that the succession of the earlier bishops is very obscure, and that the asserted apostolic foundation of the several churches (with the exception of Jerusalem) is quite destitute of Scriptural support, and has been vehemently disputed: not to speak of the question as to whether the government of the primitive Church was, in the modern sense of the word, episcopal or not. The bishop of Constantinople before Methodius, who was bishop in the early part of the fourth century, are especially doubtful.

In the fourth century the succession is perplexed by the fact occasioned by the Arian controversy; and from the sixth century, owing to the rise of the schism, there has been a double succession in the patriarchates of Alexandria and Antioch (the two names which are sometimes, from their situation, the Coptic patriarchs and Antioch: and the perplexity in the patriarchates of Antioch has been occasionally increased by the rivalry of contending Jacobites, as in the schisms of the thirteenth, fourteenth, and fifteenth centuries. After the conquest of the East and the greater part of Syria, by the first crusaders, and the capture of Constantinople in the fourth crusade, the division made was still greater by the appointment of Latin patriarchs at Antioch, Jerusalem, and Constantinople. In order to prevent mistakes, we give in Roman letter the prelates who were regarded by the Greek government and church as the legitimate holders of the see, without regard to the orthodoxy or heterodoxy of their opinions individually: the Jacobite prelates are given in italics, and the Latin patriarchs of the East in small capitals. We give the names in the usual Latin form, which, in most cases, continued in use in English books; a few cases in which the names have been Anglicized are indicated in italics, as the reader will easily recognize John in Joannes, Peter in Petrus, Mark in Marcus, Theodore in Theodorus, &c.

When two years not consecutive are assigned as the date of accession, it must be understood that the date of accession is not agreed upon, but that it occurred either in the years marked, or in the interval between them. Dates at the end of a name show that the person named was patriarch in that year or in those years, but that the exact date of accession is unknown. A, subjoined to a name, denotes Arius; M, Monothelite; C., Iconoclast; J., Jacobite, or Monophysite; H, Heretic (reputed), without reference to the nature of his heresy.

**ROSELLI, COSIMO, a celebrated old Florentine painter, was born at Florence, according to Gory, in 1439. There are few of his works remaining; the principal ones are those in the convent of Sant'Ambrogio at Florence, painted in 1456, according to an inscription upon it by Rumohr, when Cosimo cannot have been more than eighteen years of age; according to the above date, it was impossible that he was painted in his youth. And Rumohr observes that Cosimo, in the commencement of his career, followed the path which was opened by Angelico da Fiesole and Masaccio; but after a few brilliant examples of his ability, he left the approximation of the representation of things as they really appear, to follow an uninteresting, inanimate, and ugly manner. The fresco represents the transportation of a miraculously worked chalice from the church of Sant'Ambrogio to the episcopal palace; the abbots and nuns follow in the procession, and at the palace-gate is a group of priests and choristers ready to receive it: around is a crowd of curious spectators. The story is told, and the picture described, in Richa's 'Chiese di Firenze.' The picture has been engraved by Latino for his series of old Florentine paintings, and there is a group of it in Lestril's 'Etruria Pittoresca.'

Cosimo was one of the painters invited by Pope Sixtus IV. to Rome to paint the Cappella Sistina, built in 1473, by Baccio d'Angelo (Baccio della Porta), for that pope. Cosimo's paintings in this chapel are still in good preservation; they are—the Destruction of Pharaoh's Host in the Red Sea, in which the Israelites are also represented returning thanks for their deliverance; Moses receiving the Tables of the Law while the Israelites are worshipping the golden calf; the Sermon on the Mount and the healing of the Leper; and the Last Supper. The landscape of the third picture was painted by Cosimo's pupil, the eccentric Piero di Cosimo, afterwards the master of Andrea del Sarto. These works were purchased for a prize in competition with others in the same chapel by

Sandro Botticelli, Domenico Ghirlandajo, Don Bartolomeo, Luca da Cortona, and Pietro Perugino. Cosimo was very anxious to get the prize, but he doubted his ability, at the same time that he had little faith in the pope's judgment; he had, therefore, knowing his weakness in composition and design, painted his picture very high in colour, and used plenty of ultramarine and gold, counting upon attracting the pope's fancy by his gaudy display. When the pictures were all uncovered, his however was laughed at Cosimo for his peculiarities. Cosimo however proved himself a good man of the world, if not a good painter; his gay works fixed the pope's attention and he obtained the prize; the other painters were censured by his holiness for not using finer colours, and they were obliged to retouch them and heighten their effect in the same manner, to the great triumph of Cosimo, whose works however were in reality inferior to all the others.

Cosimo Roselli was still living in 1606: Vasari says he was sixty-eight years old when he died; if therefore he were born in 1439, 1507 may have been the year of his death. He was the master of Frà Bartolomeo.

**ROSELLUNI, IPPOLITO, Cavaliere, was born August 13, 1800, at Pisa. His father was a merchant, and Rosellini himself was designed for his father's business; but he acquired such a love of the study of antiquities from his first tutor, Padre Battini, a Serviant monk of St. Antonio, who was a tolerable numismatist, that he commenced at an early age to give himself up to those studies for which after wards distinguished himself, and the mercantile career was wholly abandoned. In 1821 he finished his university studies in Pisa, and took the degree of Doctor of Theology. He afterwards studied the Oriental languages for three years with the celebrated (now Cardinal) Mezzofanti at Bologna; and
in 1824 he was appointed professor of Oriental languages in the university of Pisa. In 1825 he appears to have devoted himself to the study of Egyptian hieroglyphics, following the steps of Champollion, of whose discov-
ery he was an ardent advocate. When Champollion, in
1826, for the further development of his system, examined the Egyptian monuments at Bologna, in Italy, Rosellini,
by the permission of the Tuscan government, attended him in
his researches; and he accompanied him to Paris, and there
spent the autumn of that year in similar researches: he pub-
lished in the same year 'Lettere, oramai池a finita di un disegno
monumentale dell' Egitto di Nubia,' 8vo., with four volumes of
text, 1823-41; the second, 'Tavoletta M. C.,' contains the civil
monuments, 'Monumenti Civi,' in 155 plates, four volumes of
text, 1834-56; and the third, 'Tavole MI. C. S.,' the civil
worship, 'Monumenti del Culto,' in 86 plates, with one volume
of text, 1844. An index of the whole work is said to be in
preparation by Rosellini's pupil Giuseppe Bardelli, who pub-
lished a continuation of his life at Florence in 1849. 'Biogra-
phia del Professore Ippolito Rosellini,' of which an abstract
appeared in the 'Allgemeine Zeitung' and in the 'Kunst-
blatt,' in the following year; the latter notice has been used in
the preparation of the index. Rosellini be-
quessed his Egyptian MSS. to the university of Pisa; the
drawings and plates are all the property of the Grand Duke.
Among the MSS. is a voluminous but unfinished 'Dizionario
Egiziotico,' Hieroglyphic Dictionary, with several thou-
sand names.

ROSIAN is a small tract, and a part of that immense
region of Oriental Asia which is called Persia, or Independent
Turkistan. It lies between 57° and 58° N. lat., and
between 70° and 72° E. long., but its extent is not well known, as
the country has never been visited by Europeans. It is a very
irregular region, and in some parts the mountains are high,
between which are wide and inaccessible deserts; in other
ranges which constitute the western declivity of the Boler
Tagh, and surround the elevated table-land of Pamir. Along
its southern boundary runs the river Oxus, which in these
mountains is divided into several streams, which unite to form
the Oxus, and enter the Caspian Sea. The mulb-
erry-tree is much cultivated, and the fruit is used for making
flour. Horses are not numerous: the camel with two hunches
is the principal beast of burden. Cattle and sheep, both of
the usual description, constitute the principal stock. The in-
habitants, whose number is stated not to exceed a thousand
families, speak a peculiar language. The sovereignty of
this country is dependent on the Khan of Kandah, but this
dependence is only nominal.

(Wood, Journey to the Source of the River Oxus.)

ROSMINI, CARLO DE', born in 1758 at Roveredo, in
the Italian Tyrol, studied first at Innsbruck, and then in
his native town, where he began early to show his aptitude for
literary composition by writing several disquisitions on poetry.
He afterwards removed to Ferrara, where he published in
1789 a 'De Filis Carminum Et Odiorum.' In 1793 were
added a letter by Vannetti on the style and the language
of Ovid, and a parallel between the Orphus of Ovid and the
same character in Virgil. This work obtained for Rosmini
the most signal honours in the Florentine academy. He next wrote: 'Della Vita di L. Anneo Seneca libri quatro,' Roveredo, 1793. In 1801 he
wrote an account of Vittorino da Feltre, a celebrated precep-
tor of the fifteenth century, and of his system of education:
'Idea dell' ottimo Frettore nella Vite e Disciplina di Vittori-
no da Feltre e de' suoi Disciplori.' This book may be called
a treatise on pedagogy, as well as the next work published by
Rosmini on Guarino Veronese, a contemporary of Vittorino
da Feltre, and upon his school: 'Vite e Disciplina di Guarino
Veronese e de' suoi Disciplori,' 3 vols. 8vo., Brescia, 1805-6.
In 1808 Rosmini published an elaborate biography of the
learned Filosofo: 'Vita di Francesco Filippo da Tolentino,'
3 vols. 8vo. His next work was a Life of Trivulzio, a great
captain of the sixteenth century: 'Della Istoria intorno alle
Milici Italiane del Granduca D. Gian Jacopo Trivulzio detto il Magnifico Libri XV,' 3 vols. 4to., 1811. This work was
accompanied with handsome engravings and valuable documents. The last work of Rosmini was his history of Milan: 'Dell' Istoria
di Milano Libri XVIII.' This history embraces the period from
the time of the end of the principality of the Visconti to the
year 1532, when Milan was annexed to the dominions of Charles V. The author
wrote a continuation of it down to the beginning of the reign
of the Empress Theresa in 1740, which continuation is still
inedited. Rosmini ranks among the most lucid of Italian
biographers of our times. He died at Milan in 1827. (Tipaldo, Biografia degli Italiani illustri.)
ROSSI, ROSSO DE, or IL ROSSO, called in France, Maitre Roux, a celebrated Florentine painter, was born in Florence in 1496. He studied the works of Michael Angelo, and, being impressed with his genius, he is said to have exclaimed, "I will be his equal." He executed several works in various cities of Italy, but his paintings are not numerous in Italy, as he passed the best portion of his career from about 1530 in the service of Francis I. at Fontainebleau, where he was the object of great esteem, and the superintendent of the palace, with a princely allowance, and a house in Paris, given to him by Francis. In the year 1541, however, while still at Fontainebleau, a few hundred ducats were stolen from him, and those he had been prevented from returning by a declaration of the theft, who was put to the torture and was declared to be innocent. Rosso's sorrow for what had happened, and the doubts of Pellegrino and his friends together, annoyed him to the lowest degree. After the discovery of the theft, and grief of Francis and his own pupils and assistants. He is said to have been called II Rosso on account of his red hair: he was remarkable for his large and handsome person and general accomplishments and acquisitions. Rosso was the boldest painter that had appeared in Italy up to the time of Vasari. Very few of his works were left at Fontainebleau; many of them were destroyed by his successor Primaticcio. Many of his works have been engraved.

(Vasari, Vita de' Pictori, etc.; Lettere Pittoriche; D'Argenville, Vies des Peintres.)

HANS FELIX, R.A., was born at Nottingham in 1762; his father, a native of Siena, though not a licensed practitioner, practised as a medical man at Nottingham. Young Rossal was apprenticed very early to a surgeon of the city, and after he had served his time, as a journeyman, at eighteen shillings per week; but being employed by his master to correct some work on which Locotta's principal assistants had been engaged, he suspected that his own abilities were of a superior class, and he demanded and obtained higher wages. It was now, however, having once felt the longing for praise, impossible for him to remain in his then subordinate situation, and he determined upon trying his fortune in London. There, still a boy, he entered himself as a student of the Royal Academy; and in 1781 he obtained the silver medal, and in 1784 the gold one, which entitled him to three years' maintenance at Rome. He went to Rome in 1785; in 1788 he returned to London; in 1800 he was elected an associate of the academy; and only two years afterwards, a very short interval, he was elected an Academician. He was subsequently appointed sculptor to the Prince Regent, and he was employed in decorating Buckingham Palace. He was afterwards sculptor to William IV. But he had little to do after the completion of his great public monuments in St. Paul's Cathedral;—The Marquis of Granby, in the nave; Captain Faulkner and Lord Heathfield, in the south transept; and Captains Mosses and Roo, and Lord Rodney, in the north transept. The principal of these are those to Lord Cornwallis, Heathfield, and Lord Rodney, now at last visible in the last finish of the mausoleum, which, except the second, are groups of three or more figures of the heroic size. That to Lord Cornwallis is placed opposite a Flaxman's monument to Nelson, and is in a similar style of composition, but much more vigorous and spirited. The Marquis, as a Knight of the Garter, on a pedestal forming the apex; below are three allegorical figures—Britain, and the explorations of the Bosphorus and Ganges, representing the British Empire in the East; and the Ganges has much grandeur of form. Lord Heathfield is a single statue, represented in his regimentals; on the pedestal is an altar-piece of Victory descending from a castellated rock to crown a warrior on the sea-shore with laurel. Against the same pier is the monument to Captain Faulkner, R.N., who was killed on board the Blanche frigate in 1755: Neptune, seated on a rock, is in the act of catching the naked figure of a dying sailor. Victory is abstract, and is crowned with a laurel. Lord Rodney's monument is a pyramidal group, the statue of the admiral forming the apex; below is Fame communicating with History. Art-Union J. [Companion to St. Paul's Cathedral.]

BOTTECK, KAHL WENCESLAUS ROLODEK, VON, was born on the 18th of June, 1776, at Freiburg im Breisgau, which now belongs to the Grand Duchy of Baden, but at that time was subject to the House of Austria. His father, Anton Roateck, was sent to the University of Freiburg, II, under the name Roateck von Rotteck, on account of the eminent services which he had done to his country and the emperor as perpetual dean of the Medical Faculty in the University of Freiburg, and as one of the councilors in the board of administration of Austrian S. His mother, Charlotte Pfotr d'Oegon, a native of Remiremont in Lorraine, is described as a lady of rare virtue and accomplishments. Karl von Rotteck received a very careful education, and as early as 1790 was admitted a student in the faculty of law in the university of his native town. He took the degree of doctor of civil law in 1793, and in 1798 was admitted to the bar. He devoted all his spare time towards the accomplishment of a great historical work, which secured him a high rank among the historians of Europe. Of his 'Allgemeine Weltgeschichte,' ('Universal History') the first volume was published in 1811, but it was only finished in 1897. Germany having recovered its independence through the treaties of 1814 and 1816, and political liberty having been promised to its inhabitants, Rotteck's law was rejected by the states; of Germany, as an object of his particular attention; and desiring to propagate his ideas, gave up his chair of history, and petitioned for that of politics and the law of nations in the same university, which he obtained in 1818. On those subjects he published a great number of works and memoirs as well as articles in the leading liberal periodicals of Germany, and the princes of Germany being then active in checking the rising liberal spirit of the nation, he obtained great popularity. In 1836, on his taking his university as their representative in the first chamber of the States of Baden. In the same year appeared his 'Ideen über Landstände,' ('Idea on Representative Bodies:') a work discussed and attacked by the German historians, and especially distinguished by great ability and an elegant and attractive style, for which he is remarkable among the German historians and publicists. Some time afterwards he wrote a work on standing armies, the danger of which he endeavoured to show, and a history of the States and Cities of States of Baden, which were well received by the people, but made him many enemies among the friends of the old state of things. Thus, lecturing in the university, propagating his liberal views through countless minor productions, and representing Freiburg in the states, he continued till 1830. The outbreak of the French revolution in 1830 gave fresh vigour to his activity; he became the leading spirit of the party among the liberal periodicals of Germany, several of which were founded by him; and giving up his seat in the first chamber of the states as member for the university, he accepted the membership for the city of Freiburg, which he placed him in the second chamber, among the representatives of the people. At the head of those members who by their unremittent zeal in developing political freedom in Baden set an example to all Germany, Rotteck was exposed to slander, the cause of which is, that he, in the year before France had subdued, the German governments took courage to punish those who had given offence. In consequence of a decree of the Diet, in 1833, the Baden government forbade Rotteck to deliver a public lecture in the University, which he had for Ritchfor, for five years, the right of editing any newspaper. Germany now looked upon him as a political martyr, and from its most distant provinces he received addresses and letters. His name was proposed as a candidate for the representa- tions of the people. The latter refused to give their sanction: they likewise tried to exclude him from the second chamber of the states, and to prevent his re-election; but there they failed, and from 1830 to 1840 he continued to represent Freiburg without any inter-
ruption. In 1840 the Baden government re-admitted him as a lecturer at Freiburg, but it was too late; after a severe illness in which the worst symptoms of the disease from which he had been exposed, Rotteck died on the 20th of November, 1840. His death was mourned as a public calamity in all Germany.

The principal work of Rotteck is his Allgemeine Weltgeschichte mentioned above, which extends from the commencement of authentic history to 1815. It went through three editions, the last with a continuation of the history of the years from 1815 to 1840, by K. H. Hermes, Brunswick, 1841-45, 11 vols. 8vo., of which nine are the work of Rotteck, and the two last the continuation of Hermes. No general history has produced such popularity as this did in the production of Rotteck; in Germany it is in the hands of almost every educated family; its fame spread over Europe and America; and it was consequently translated into most of the European languages. The English translation by T. Jonas, Philadelphia, 1840-42, four vols. 8vo., 2nd edition, London, 1842, is a however only a translation of an extract of the General History, which Rotteck published under the title Aeng aus der Weltgeschichte, Freiburg, 1831, 8vo. four vols. 8vo. Contrary to the practice of most German historians, Rotteck simply relates history, indulging neither in critical investigation of tribes, nor in metaphysical contemplation of the broad facts of human deeds. But the whole work is presented from a liberal point of view, and enlivened by sound reflections on the origin of freedom and slavery, and the causes of the rise and fall of nations. The style of Rotteck is clear and attractive, but too much is the desire for retrenchment; the narrative is interrupted; and every page shows that the author possessed that rare taste and that discretion which enable a man to distinguish between trifles and important facts, and to give neither too much nor too little. The reader who wishes to obtain a strong impression of the peculiar merits of this work, as the production of a German historian, need only compare it with Hamburger's far-famed History of the Turkish Empire. Among the other works of Rotteck may be mentioned: beside the legal and historical works, (Postel as a Metaphysical Science, and of Public and Constitutional Law,) four vols. 8vo., 1829, &c.; Staatsrecht der Konstitutionellen Monarchien (The Public Law of Constitutional Monarchies); three vols. 8vo., 1824, &c.; Rotteck was the co-editor, with Welcker, of that excellent work Staatsgesetze, vol. (Political Dictionary), which is still unfinished.

Dr. Hermann Rotteck, the son of the late historian, published Rotteck's Nachlass in 1842, as well as a volume of English Seins in 2 vols. (Minor Works), five vols. 8vo., 1829-35, which contain a great number of valuable memoirs, essays, letters, &c., on various highly subjects; Lehrbuch des Verfassungsrechts und der Staatswissenschaften (Doctrine of Law as a Metaphysical Science, and of Public and Constitutional Law), four vols. 8vo., 1829, &c.; Staatsrecht der Konstitutionellen Monarchien (The Public Law of Constitutional Monarchies), three vols. 8vo., 1824, &c.; Rotteck was the co-editor, with Welcker, of that excellent work Staatsgesetze, &c. (Political Dictionary), which is still unfinished. Dr. Hermann Rotteck, the son of the late historian, published Rotteck's Nachlass in 1842, as well as a volume of English Seins in 2 vols. sword of the Saracen, and had been made prisoner, with the remnant of his host, by the Mohammedans. Louis, however, was soon released upon paying a ransom, and entering into a treaty with the Soltan; and he was in Palestine in 1253. Although some accounts have reached, and been generally be- In quest of that great, undiscov erable, Christian potente of the East, Prestor, or Priest John, had returned disappointed, and with very discouraging accounts of the difficulties which lay in his way, he did not decline to charge his imagination of that visionary personage; and being more anxious than ever to contract an alliance with that fancied Christian prince, he resolved to send another mission in search of him, and to have some certain information of the Tartar, Sartach, son of Bauto-Khan, who commanded in the western parts of Tartary, was a good Christian. If this Sartach were not Prestor John, still his faith and devoutness, if truly reported, must make him a valuable ally to the Christians who were warring in the Holy Land against the Paynim. The mission of Louis was, therefore, to find, that Tartar prince, where he might be, and to whatsoever end and danger. It was composed of Rubruquis, friar Bartholomew of Cremona, and a certa n friar Andrew, whose country or birth-place is not named. Rubruquis, though the youngest of the three, appears to have been considered as the head of the mission. He, no doubt, owed this pre-eminence to his superior scholarship, wit, and courage. Before his departure King Louis strictly enjoined him to write down everything he observed, in his own hand; and, as well as he could, in order to keep a full account of all that was done, and of all that was said; and, above all, in order to keep a record of the conduct and movements of the Tartars, who, as usual, were conducting their flocks and herds with them, he procured a guide and pushed rapidly for Sarai, keeping due South; and arrived at Cherson, the most considerable place in the journey, the dangers and fatigues of which were supported with admirable temper, and in the course of which he threaded the great defiles of Mount Caucasus, crossed the Araxes, and traversed Armenia, Persia, and Asia Minor. Rubruquis reached Tripoli, in Syria, in the month of August, 1255. He had been, altogether, about two years and six months on his laborious travels, and he now earnestly besought his superior in France, Louis, to set him free; for the French prince had quitted the East after witnessing the failure of all his hopes. But the Franciscan provincial, being a strict disciplinarian, ordered the poor friar to write to Louis, and then retire to the convent of his order at Acre. The manuscript account of the travels was soon transmitted to Paris, together with an earnest prayer that his Christian Majesty would obtain the provincial's permission for his going, for a short season, to France. It has not been ascertained whether he obtained the favour, or whether he remained shut up in his cell at Acre. Indeed, after his return to Syria, nothing more seems to be known about Rubruquis except that he was living in the year 1260, when he died. He is thought to have kept on his way back to Europe from the remotest regions of the East. He was a man of rare good sense. The sobriety of his descriptions is marvellous for the time in which he lived. He was beyond a doubt the first and only European traveller that gave a correct account of the Caspian Sea. (Hakluyt, Collection of Voyages and Travels, A.D. 1600; Purchas, his Pilgrimes, 1615; Recent Edition of Rubruquis' Travels from a MS. in the British Museum collated with other MSS. at Cambridge and Leyde, published by the Geographical Society of Paris; Charles Mac Farlane, Romance of Travels.)

RUFFO, FABRIZIO, born about the middle of the eighteenth century, was a younger son of a noble and wealthy Neapolitan family. He was brought up for the church, for which however he had little disposition. Being introduced at Rome to Pope Pius VI., he was in a manner by which capacity he exhibited considerable economic abilities, and he incurred the jealousy of many of the older members of the Roman court. At last, he resigned his commission, offered himself, to France, and became Ruffo, and appointed him intendant or chief administrator of his palace and domain of Quaetta. Ruffo was fond of agriculture, and it was there he supplied his leisure. He had no great stock, and when King Ferdinand was driven away from Naples by the French republican army in 1798, Ruffo followed him to Sicily. He had disapproved of the provocation given to the French, and he revolted against his sovereignty to the court of France, which sent Dumas, the French consul, with the favourite minister Acton. The latter, in order to get rid of his presence, recommended him to Queen Caroline as a fit man to recover the kingdom of Naples by placing himself at the head of the Royalist party, who was in

P. C. S., No. 149.
which province the family of Ruffo had large estates, and exercised considerable local influence. The queen approved of the plan, however hazardous it might appear, and made the king sanction it by bestowing on Ruffo the rank of his vice-regal representative in the province. Ruffo had not only to escape from the intrigues and vexations of the court of Palermo, accepted the office. In February, 1799, he crossed over in a boat with an escort of only five men and 5000 ducats, and landed at Ragusa, a rib of his family. He collected a number of adherents, and unfurling the royal flag with a white cross, proclaimed a crusade against the French and their partisans. The republicans of Naples had committed many errors of judgment, and had exaggerated the rustic population, which were not ripe for the change from old absolutism to a republican form of government. The Calabrians flocked by thousands to Ruffo's standard. The army of 'the Holy Faith,' which was the name it assumed, marched to the town of Monteleone, which surrendered by capitulation, as well as Catanzaro; it afterwards stormed Cosenza, which was given up to plunder; took Coenzia though the treason of its commander; and thus in less than a month Ruffo was master of all Calabria, where he re-established the king's government. He was joined by many regular officers and soldiers, and was supplied with artillery. He then took the road to Apulia, and laid siege to Altamura, which opposed his passage. The inhabitants defended themselves desperately, but the town was taken and plundered for three days, incommensurate with proportion. The provincials in other parts of Apulia hoisted the royal flag; the Abruzzi was already in open revolt against the republicans of Naples, who were soon after abandoned by the French troops, which were retreating from Mayence towards North Italy, in order to oppose the Austrians and Russians, who were predominant in that quarter. Naples was left to its fate with only a small Frencharrison in one of the castles. On the other side, Ruffo was joined by some republican Italian and Albanian forces from Corfu. He then advanced towards Naples by Avellino, and surrounded the capital at the head of fifty to sixty thousand men, mostly irregulars. After some fighting outside the city, he mounted an insurrection in the province, which lower crept and within facilitated the entrance of Ruffo's bands, and the town became a scene of carnage; but the republicans still defended themselves in the castles and the adjacent districts, where they had fortified the massive palaces and houses. Ruffo, willing to spare further destruction, entered into a convention with the republicans, who were to be shipped off for France. The capitulation was signed by him, and a part of the republicans were actually sent off to France, when King Ferdinand arrived from Sicily in the bay, at the end of June, on board the English admiral Nelson's ship, and refused to sanction the capitulation. Ruffo had exceeded the powers in treachery, with rebels, and he appointed a special court to try the republicans, many of whom, chiefly of the higher orders of society, were put to death. The minister Acton charged Ruffo with having called for the Jacobins, for they were called the Jacobins and the cardinal, disappointed and humiliated, seized the opportunity of leaving Naples for the conclave, which had been summoned to assemble at Venice for the election of a pope. Ruffo followed the new pope, Pius VII., to Rome, where he was made Prefect of the Annona. Some years after he returned to Naples, where he resumed his place at the court. When the court of Naples was obliged to emigrate a second time to Sicily in 1805, in consequence of its own imprudence and tergiversations, Queen Caroline proposed to Ruffo to put himself again at the head of the country people to oppose the French, but Ruffo replied that 'once was quite enough,' and that life for such a event was more suitable. He went to Rome, where he remained till 1809, when he went to France and made peace with Napoleon, and he was one of the censors who sanctioned by his presence his second marriage.

In 1814 he returned to France, and was made Pope, Pius VII., who died after a few years. After his death Ruffo returned to Naples, and took again his seat in the council, where he displayed a marked moderation of sentiments. He went to Rome in 1828 to the conclave in which Leo XII. was elected pope. Ruffo died in 1830, and was succeeded by his brother, who continued his work.

Ruffo was a man of ability and accomplishments. He was worldly and lax in principles, by no means fanatical or convertible, which, for his own time, was a romantic expedition of 1790 cannot be justly attributed to him, although he may be blamed for not reckoning on them before he put himself at the head of the insurrectionary movement. Troubled in all things, the inhabitants of the province of the republicans of Naples had assumed a task beyond their strength; they misflew their own coterie for the nation, and they suffered cruelly for it, for the people were not on their side. The same error has been repeated again and again in other countries in our times. There is a graphic sketch of the adventures of Ruffo's life, in the Chronicles of the popular Tumults, published by Knight & Co. in 1837.

Contemporary with this Ruffo, there was another Cardinal Ruffo, of another branch of the same family, who was long archbishop of Naples, and a great writer and scholar. (Petrornati, Stella della Spedizione del Cardinal Ruffo; Collettta, Storia del Reame di Napoli; Coppi, Annali d'Italia.)

(Zimmern, Geschicht des Eim. Privatrechts, i. 889.)

RUGENDAS, GEORG PHILIPP, a celebrated German battle painter, was born at Augsburg in 1696. He was the pupil of Isaak FLeche, an eminent historical painter in his time; but Rugendas devoted himself at an early age almost exclusively to battle painting, in which he was partly conformed by the admirable battle-pieces of Bourgeois, Lemnike, and Tempes, which he studied on his journey to Venice, and afterwards by the pictures of the Flemish Schild-Bent, or Society of Painters, in which he was received, from his predilection for battle painting, under the nickname of Schild: all the members of this society were known to him.

In 1759, after an absence of five years, he returned to Augsburg, and had the opportunity of witnessing its siege in 1758, and of thus studying from nature what he had hitherto only acquired from his imagination and from the pictures of others. He lost a great portion of his property through this siege, but what he lost in substance he more than gained by excellent opportunities he found of perfecting himself in the line of battle-painting, and he acquired extraordinary excellence as a battle painter; and became distinguished also for his etchings of battles and skirmishes: he excelled in the manner in which he represented smoke, and made use of it in separating and arranging his groups. There is or was a large picture of the siege of Augsburg in the Stetten collection at Augsburg. Rugendas was made director of the Academy of Augsburg in 1710: he died at Augsburg in 1742. His pictures are very numerous, and there are not many collections without one or more examples of his style. He painted besides battles and skirmishes, horse-markets, and horse-racing, but he was particularly celebrated for his pictures. His design is vigorous and bold, but his colouring is unequal, sometimes being high and warm, and at others heavy and monotonous: and though his light and shade is often well adapted to the subject, it is too generally from black and obscure. Owing to an illness he painted many years with his left hand. There is a picture of the battle of Blenheim by Rugendas. He was the ancestor of a numerous family of painters and engravers, sons and grandsons. A Life of him by J. C. Fussli was published, together with a Life of Kupetzky, by the same writer: Leben Georg Philipp Rugendas und C. Johann Kupetzky; Zürich, 1746.

Christian Rugendas, his second son, engraved about sixty of his father's designs in a very spirited manner, chiefly in mezzotinto. His own etchings, of which there are about thirty, are also highly meritorious. RUCH. RACHEL, a distinguished Dutch painter, was born at Amsterdam in 1644: she was the daughter of Professor Ruysch, who had taught flower-painting by Willem Van Deelen. In 1656 she was married to the portrait-painter Francois van Mieris, who died two years her junior, to whom she bore ten children and with whom she lived fifty years. In 1701 she and her husband were elected members of the Society of Artists of the Hague, and in 1708 John Williams, a member of the Pia, is recorded aged 98. She died at Amsterdam in 1760, aged eighty-six, and she continued to paint till she was upwards of eighty years old. Her works have been described by J. van Sichem. De Heem, and have sometimes been sold for very high prices, even 8,500 francs for a single picture.

(Van Gool, Nieuwe Schouburgh der Nederlandse Kunst schilders, 1724; Cabinet de Peinture de M. de Tilly, Giesch iden der Vaderlandsche Schilders, &c.)
RULER, PARALLEL. A good form of this instrument is explained in Marquay's Rulers, P. C. S., which is particularly applicable to the case in which numerous and related parallel lines are wanted. Such a form of parallel lines is a kind of two, which might well be called parallel rulers and parallel rollers.

The principle of the common parallel ruler is a parallelogram of certain dimensions, the history of modern mechanics, according to which, the angles altered, the other side changes, and the angles are the same. The first postulate, to the first side of its parallels. Two rectangular rulers are connected by two crossbars, and are often found in schools and style books. He says that in such a manner that the four pivots, two in each ruler, shall be the four points of a parallelogram. The line joining two pivots on the same ruler is always parallel to the length of the other. One ruler being held fixed, and a line drawn with the edge of the other ruler in any position, then any motion given to the other ruler by the rotation of the crossbars gives, on the edge of the moving ruler, a line parallel to the first line. The defects of this construction are, that the four pivots may not make an accurate parallelogram, in which case the instrument is worthless; and the sides of the two rulers, when the instrument is closed, may not be parallel to each other, in which case all the lines must always be taken off the same ruler. Moreover, one ruler remaining fixed, there is but a small command of distance from it; so that, to have the parallel required, it may happen that the first ruler has been taken on, a first guess, an advance again, and so on. Now, owing to the rotation of the pivots, this gives an oblique line in the instrument; so that it is only the case, in which the required parallel is given, the point from which it is to be drawn is off the ruler. To meet this disadvantage, and to give the instrument more content, three rulers are sometimes put together, each connected with the next by cross-bars in such manner that the cross-bars connecting the first and second have an opposite revolution to those connecting the second and third. At its best however this instrument is rather clumsy; but, such as it is, it is safe and easily used, when well made.

The simplest kind of roller is the common round roller, which, with a little practice, will draw parallels for ordinary use very well. It is good practice in the use of instruments to draw parallels in this way; the roller being held in the middle and gently allowed to take its own rolling motion. If a ring be well drawn round the roller, it is good practice in drawing perpendiculars to adjust the roller so that the ring may roll over the line to which perpendiculars are to be drawn. But a roller which is more easily used is sold in all the shops. It consists of an ordinary roller of rectangular form, both edges of which are bevelled and divided into equal parts. The instrument is shown in the picture; the inch divisions being made to come exactly opposite each other. A roller is let into room cut out of the middle of the roller, in such manner as to project a little way, so that when the instrument is put down on the paper, either of the bevelled edges may be brought down on the paper, or both may be clear of it. In this case the roller (the efficient ends of which are strengthened) is used as a friend, and rolls easily, and additional stability is given if, while it rolls, one of the bevelled edges be slightly placed on the paper. The ends of the roller are graduated and a fixed index is in the frame, so that by allowing equal numbers of divisions to pass the index at each roll, a good approximation (though not quite with a draughtsman's accuracy) may be made to equal divisions of the parallel. Perpendiculars to a given line are drawn by adjusting the roller so that one edge of the bevelled edge may travel on the given line. With very little practice this instrument is of great power and accuracy. Before using it, draw a line with it, roll it away, and then roll it up again to that line, and see if the coincidence is as perfect as before. Various other modes of trial will suggest themselves; indeed no one should use a parallel roller at all until he has drawn pairs of parallels across each other, and satisfied himself that he can get the opposite sides quite straight.

A rough construction of this kind is now (very recently, September, 1846) sold under the title of 'Schleisinger's Parallel Roller,' and has been brought out by a firm of instrument makers, and sold with a flat bevelled roller, so as to carry it when it rolls. This is meant to rule lines for writing, but it may be made to do good service as a parallel roller for other purposes.

VON Distinct writer on art, was born of an old family at Reinhardsgrimma, his father's estate near Dresden, in 1785. He was educated at the Gymnasium, or high school of Holzminden, in Brunswick, whence he went to the university of Göttingen. From this institution he neglected every other study for that of art, abruptly discon- tinuing his studies at the university and placing himself with the painter J. D. Fiorillo, well known as the author of a general history of Rome, and a person of extensive evenings. From Fiorillo Rumohr heard much about Italy which excited his imagination and determined him to visit that country as soon as he had acquired some knowledge of the various languages, and in order to prepare for his journey he went to the university of Göttingen, where he acquired a knowledge of the languages of the Low Countries, and in this was imitated by Cambrai. From 1804 to 1816 Rumohr went to Naples, and there commenced the formation of a collection of antiquities; he had already been collecting prints for some years. He returned to Germany in 1806, in the company of Ludwig Tieck. In Bavaria he was honoured with the confidence of the crown prince, the present King of Bavaria. From 1806 to 1816 he lived in the little art city of Holstein. Though he took great interest in the political changes of that time he meddled very little with them. His literary activity was connected with his work, and he published essays on various departments of art, and among them a work entitled 'Sammlung für Kunst und Historie,' at Hamburg, in 1816, 2 vols. 8vo.

In 1815 he revisited Italy, and commenced in Florence the researches for his principal work, the 'Italienische Forschun- gen,' of which the three volumes were published in two portions in a later period of his life. In Rome he found Overbeck leading the German artists into a new or rather old sphere of art, of which a conventional sentimentalism is the principal feature, and which forcibly impressed Rumohr. In 1827 appeared at Berlin the first and second volumes of the 'Italian Researches' (Italianische Forschungen) a critical work on the history of art, and compiled exclusively from the original archives and documents in various buildings at Flo- rence, in this work Rumohr clears up many obscurities and cor- rects several errors, and brings to light new facts. In 1835 he went to Italy, when he was consulted in the purchases for the new picture-gallery which was then being established at Berlin, and he acted as Cerievos to the present King of Prussia in Florence, where he paid the visit of a friend. He returned to his native country, and in 1839 was appointed professor of history of art in the University of Ulm, where he died, in 1846. Rumohr was a friend of the curators of the Munich Museum, and of various literary works now followed in rapid succession and on various subjects. In 1832 appeared 'Römische Geschich' der Kunsthistorik, at Stuttgart; 'Deutsche Denkmiüden,' at Berlin; 'Drei Reisen nach Italien,' at Leipzig; and the first volume of his 'Novellin,' at Munich, in 1834. 'Sule der Hölleflelf für Alm und Jung,' at Stuttgart; and 'in the Leipzig pocket-book Urania, Der Letzte Serrufl,' at Berlin, which was the first of a series on the history of art in Germany, and was continued in Munich, the second volume of 'Novellin,' and in Lübeck, 'Kynoleopomachia, der Hunfchustreit, mit Bildern von Speckter,' Dog Hunter's Fight, a satirical poem on the times. Erwin Speckter was a good artist of History of Art, admired by Rumohr: he died in that year. [Speckter, Erwin, P. C. S.] In the same year also appeared the History of the Royal Collection of Prints at Dresden, by Rumohr and the keeper of the collection, Professor Thiele; and at Leipzig, Contributions towards the History of Art and the greater completeness of the Works of Bartsch, by a member of the Royal Society, and newly pub- lished at Leipzig two works on wood-engraving, 'Haus Holbein der Jüngere in seinem Verhältniss zum Deutschen Formenschatz,' and an answer to a censure of this work, 'Ueber Verlassenheit des berühmten Meisters Rumohr.' Jacob, the Sachsgudnngen against the Schrift Haus Holbein.' &c. These
were followed, in 1837, by a treatise, 'Zur Geschichte und Theorie der Formschöpfung.'

In 1838 he made a fourth journey into Italy, but he did not go to Florence, as his tour was mainly on business. His views then as an artist. He published an account of his journey at Liibeck in 1838, under the following title:—

Reise durch die östlichen Bundesstaaten in die Lombardie und die Toscania; zu welcher er mit den politischen Aufgaben seiner Bischofsberufung auf Völkerkunde, Landbau, und Staatswissenschaft; — to which he published some additions in the following year.—Historische Beilcke, &c. He had produced a sketch of the art of the period in a new and friendly manner,— Über die Besitzmöglichkeiten der Colonien im Neu- en Toscana, aus den Urkunden; Hamburg, 1830. In 1841, however, after a fifth visit to Italy, to Venice, in the previous year, he returned to his more general subject the history of art, and published in Leipzig an inquiry into the invasion attributed to Finiguerra of printing with engraved plates on damper paper—Untersuchung, dass Mano di Finiguerra Einbild des Haaggriffen sagt gestochen Metallplasten auf genesse. Papier abzudrucken. This was his last labour in the history of art, and his last poetical production of this class was 'Raphaele Lenzl und Wander-Jahre.'

In 1843 he purchased a house in Liibeck intending to end his days there, and he fitted it up according to his own fancy. The winter of 1843 he spent in Berlin, and he was then attacked with water on the chest: he returned in the spring to Leipzig. Lenzl recommended him to visit the baths in Bohemia; he accordingly set out, but being too ill to proceed he remained at Dresden, where he died of apoplexy July 25, 1843.

His last literary production was a preface to—Kampf
Demokratischer und Aristokratisher Prinzipien zu Anfang des sechszehnten Jahrhunderts,' Liibeck, 1843. It is a translation from the papers presented to him by Professor of number of Bruns. His 'Italienische Forschungen' will remain as a monument of his judgment and industry when probably nearly all his other works are forgotten. It is one of the best documentary works in the literature of art, and at the same time abounds in critical and theoretical reflections; it is likewise a work of great interest, though there may be different opinions about the correctness of Lenzl's theories. The two first volumes are upon modern art in Italy generally, from its origin to its decline in the 16th century, which is distributed under fourteen distinct heads; many errors in Vasari are corrected; much obscurity of the 12th, 18th, 14th, and 18th centuries is cleared up by authentic documents; and various false notions concerning the development of art are dissipated by critical reflections: the third volume is under two heads only, which treat chiefly of Raphael, and the artists of the next and present age.

(Kunsthifti, 1844.)

RUNCIMAN, ALEXANDER, an eminent Scotch painter, was born at Edinburgh in 1790. His father was an architect and he was taught the arts of painting during his childhood, and he made coloured sketches in the fields as early as his twelfth age. At the age of fourteen he was placed in the studio of John and Robert Norris, John being considered as a journeyman painter and his brother, for about only nineteen years of age he set up as an independent landscape painter in Edinburgh, but it seems the people of Edinburgh, like those of many other places, though lavish of their praise were very cautious in their purchases, and Runciman had the gratification of dwelling on his own pictures, for they were left on his hands. This state of affairs continued for about five years, when in 1796 he took to historical painting, understanding he had more ability in this part of his art it seems to have been very little if at all improved. In 1798 he visited Italy, and at Rome made the acquaintance of Fuseli. Their tastes in art were very similar: both were absorbed in what is termed the sublime, and both were alike wild and extravagant in their execution. They were, says Allan Cunningham, 'rivals in that unhallowed licence of imagination, which introduced an air of inspired madness and considered extraordinary powers in the delineation of the stoutest subjects of which they employed their pencil.' Runciman remained five years in Rome, and when he returned home he carried from that country the innovations to British art, which were the following passage:—'I send this by the hands of Runciman, whom I am sure you will like: he is one of the best of us here.'

He arrived at Edinburgh in 1797, a fortunate time for him, for Pavilion, the director of the new academy of the arts which had been established at Edinburgh in 1790, had very recently died, and Runciman was appointed to fill his places, with a salary of 120l. per annum, then a sufficient income to support a young artist. He had two of the best patrons in Sir J. Clerk, of Pennycook, and Robert Alexander, an Edinburgh merchant. The former employed him on a great work at Pennycook, suggested by himself, neither of which was proceeded with; the latter employed him on twelve great compositions from Macpherson's Ossian, which at that time was believed in Scotland to be authentic. The subjects are—Ossian singing to Malvina, the Valour of Cunnavor; the Battle of the Moors; the Death of Catholus; the Finding of Corban Cargius; Gogloosa mourning over Lamderg; Oina Morval; Cormac attacking the Spirit of the Waters; the Death of Cormac; the Hawaiian Wind; the First Visit to the Island of Inis Oirr; the Finding of the Spirit of Lua. The picture of Aganeerca is reckoned the best. One cannot but respect the enthusiasm of the painter of such a series as this, but as works of art they are extravagant in treatment and in composition, and incorrect in design. While engaged in this work Runciman painted also 'The Ascension' on the ceiling over the altar of the episcopal chapel in the Cowgate of Edinburgh. He painted also King Lear; Andromeda; Cassandra and her nymphs surprised at the Water Side by Ulyses; and Agrigippa landing with the Ashes of Germanicus.

Runciman visited London in 1772 and exhibited some pictures there. He was greatly admired, and was much remembered by, says Allan Cunningham, is that he took up his quarters with the widow of Hogarth, who was in those days reduced to let lodgings for subsistence. Runciman died suddenly before his own door in West New-street, Oct. 21, 1798

In every year he had contracted an illness while painting the彭尼 cuick cupola, being forced to lie much on his back, and to this is attributed the deformity of his life. Runciman's best works are his sketches; his faults are only multiplied in his pictures. The most offensive of his peculiarities of design is his huge length and uniformity of limb, the glaring defects also of the work of Fuseli; he was also invariably extravagant in his attitudes, and was conventional, mannered, and unnatural in his draperies. Indeed, to the precise and academic taste, the works of Runciman will, says Allan Cunningham, be ranked among the crude attempts of arrogant imbecility. In execution he was least defective in his colouring, but in composition he was ever ready, and his invention was grand and fertile. There are a few etchings by him from his own designs: the best is considered 'Simonsen weeping over the Heart of Tancred.' He is said to have lived very agreeable in conversation; Hume, Robertson, Lord Kames, and Monboddo were among his associates.

(Cunninghams of Emlyn, Sketch Painters, &c.)

RUSSELL, WILLIAM, LL.D., the son of poor parents, was born in the county of Selkirk in 1741, and educated, very imperfectly, in the country and in Edinburgh. He served as a page in a regular regiment of foot, after which he went on a journeyman in Edinburgh, edited a collection of modern poetry and executed a translation of a tragedy of Crebillon, which was submitted to Garrick, but rejected. In 1797 he went to London to seek his fortune for some time, having nothing better than a place as correct of the press for Strochman the printer. While so employed, he contributed to periodicals, and published unsuccessfully several poetical and other works, among which was a History of America. In 1799 appeared the first two volumes of the meritorious and popular compilation by which he is now known, 'The History of Modern Europe.' The third, fourth, and fifth volumes, bringing the narrative down to the year 1760, were published in 1799. In 1787 he married, and took up his residence on a farm in Dumfriesshire, where he spent the remainder of his life. In 1793 he published the first two volumes of a 'History of the Ancient World, from the Creation to the Accession of George III.' These unfinished works, however, as well as several tragedies and comedies, were stopped by his death, which occurred in the year 1793.

RYLAND, WILLIAM WYNNE, one of the best Eng- lish engravers of the eighteenth century, was born in London in 1732. He was apprenticed to F. Bewer, a French engraver, who was settled in England. After the completion of his term of apprenticeship he went to Paris, and studied there chiefly under Le Bas for five years. He did not con- fines himself however to engraving, but applied himself also to manuscript drawing, and etching, a master of eminence, and
after whom he engraved, besides some others, an excellent plate of Jupiter and Leda; he also etched some plates after Oudry while at Paris, illustrating the fables of Fontaine.

Soon after his return to England Ryland was appointed engraver to the East India Company, an office he continued to hold till his death, in 1785. He engraved two portraits of George III. after Ramsay, and one of Queen Charlotte holding the Princess Royal on her lap after Cotes; it was one of Cotes's principal works. 'It is very evident,' says Mr. Hacker, 'that his engraving of the Princes of Wales is one of the most spirited plates engraved by any of the early English Engravers, that Ryland's engagements in the mercantile line as a prizetrader, deprived him of so considerable and so precious a part of his time, and prevented his pursuing the arts with the spirit and assiduity which was necessary, when his health seemed formed for great and extensive exertions. The works which he has left behind him abundantly prove that he had sufficient knowledge and judgment to have carried them to great perfection.' These last words refer to the sad event which abruptly put an end to Ryland's labours and life at once, but which Strutt, who must have known Ryland well, does not more particularly allude to. He was executed for forgery in the prime of life, July 29th, 1785.

Strutt, whose work was published only two years after Ryland's execution, seems to have abstained, from delicacy probably towards his widow, from a more particular notice of the disgraceful termination to his brother engraver's otherwise successful career. As this case is not known and as Ryland persisted in his innocence to the last, it may be here briefly related as the facts appeared on the trial:—Ryland appears to have committed himself to the charge of forgery commercially engaged as a prizetrader, has been already noticed. He had once failed in this business, but he afterwards honourably repaid all his creditors in full, though not before being seized by a shoemaker and the engravers of the East India Company in London appear to have detected several forgeries of their bills, and suspicion attached to Ryland, apparently more in one case. He recovered by however intimation of his impending arrest, and by the advice of his wife concealed himself, whereupon the East India Company immediately offered a reward for his detection. He had concealed himself in the establishment of a shoemaker at Stepney, having once given the man some shoes to mend, the shoemaker discovered the real name of his lodger, and gave notice to the police. When Ryland found that he was discovered, in a fit of despair he attempted to cut his throat: the attempt failed, but he seriously injured himself. A true bill was found against him by the grand jury, June 5, and he was tried at the Old Bailey July 26, before Judge Buller. The specific charge against him was for forging and uttering knowing to be forged a bill of 210l. on the East India Company. The case for the prosecution was this:—Ryland had uttered or negotiated two bills of 100l. each on the East India Company for 210l. and at the same date, the original bill in May, 1782, and the forged bill in November of the same year. The two bills were so much alike that none could swear which was the true bill, except by a comparison of crosses on the paper which had passed; and, what was of chief importance, the paper-maker gave evidence to the paper of the other bill being made after the date of the bill. The first bill had been fairly negotiated, but the party from whom Ryland asserted that he had received the second, a Mr. Haggleston, was nowhere to be found. These facts and the circumstances of his flight and attempted suicide were urged against him by the counsel for the prosecution. Ryland made his own defence, but owing to the soreness of his throat from his recent attempt, it was written, and read by the clerk of the court: the following were its concluding words, as reported in the Morning Herald of this day:—'Judge, I conjure thee in the name of God to forgive my guilt by my flight; but let thee figure to yourself the fears, the dread, the horrors, of an honest mind, pursued by officers of justice, to take my life, if I could not prove my innocence. I have spent a part of my time in these, the entreaties and prayers of a fond, loving, and beloved wife, and then concluded my guilt from my flight. They have also presumed to drag into evidence my attempt on my own life. I confess the accusation, and see no defence in the nature of insanity; how then will they, how can they, torture insanity into a proof of my guilt!

Two bills, one a good one, one a bad one, have been ascribed to me by some. I am willing to try the case. What is the true, can any man say either is the forged one? Mr. Holt, from his infirmity, may easily make a mistake; and where then is any forgery? I cannot think that the court and jury will sacrifice my life to presumption, and, where there is no possibility of innocence, take it away on groundless suspicions.' He was found guilty of uttering the bill knowing it to be forged.

After the verdict was pronounced, which he bore with the greatest calmness, he merely observed,—'I dare not challenge the justice of my verdict: I am, however, conscious of my innocence; and I hope that my life will be preserved by the king, if not in justice, at least on one account, because it has long subsisted.' He heard his sentence pronounced without being moved, and retired from the court as if unconcerned in the proceedings. He was executed at Tyburn on the 29th of August, about twelve o'clock, before a large number of spectators, who were well satisfied with a single room which commanded a view of the barbarous and disgusting exhibition: so great a concourse of people had not met for a similar purpose since the execution of Dr. Dodd six years previously.

Character and probability were much in favour of Ryland's innocence, though circumstantial evidence was against him. He was wealthy, according to his own account. Besides the salary of 200l. per annum as engraver to the king, he exercised a very lucrative profession, possessed a great stock in trade, and had a large property in the Liverpool water-works. And many witnesses had been heard before the king's commission to say that Ryland was the most agreeable of men, so much so that the informer, Mr. Strutt, had to testify that he was a man respected and beloved by all that were well acquainted with him; for few men in private life ever possessed more amiable qualities than he did. He was a tender parent, a loving husband, and a considerate father. He frequently straitened his own circumstances to alleviate the sorrows of others; for his heart was always open to receive the solicitations of distress.

Ryland introduced chalk-engraving (lines composed of dots) into England, and in the latter years of his life devoted himself exclusively to engraving in this style, in which he had no equal, but chiefly, except a few drawings by the old masters, after the works of the English school. That art, however, like all others, is to be regretted, as the works of that lady have little to recommend them to the lovers of art. Ryland engraved twenty-four prints after Angeliers, and one of these, Edgar and Elfrida, a large plate, which was finished by Sharp for the benefit of Mrs. Ryland, is one of his principal works. King John ratifying the Magna Charta, a large plate after Mortimer and in a similar style, was given in connection to it. Ryland left this plate also unfinished, and it was completed by Bartolozzi, likewise for the benefit of his widow. It is his best plate in this style; but the best of these chalk engravings have been the medallion mezzotinto engravings: the style was, however, like the in-sipid drawings of Cipriani, much in vogue in the time of Ryland and Bartolozzi. As an etcher, where the needle and graver are combined, Ryland was also excellent. The prints which he engraved in France were executed in this style, and Wattelet terms his execution in this style most picturesque, and adds that one would suppose his etchings to be the work of a painter. The chalk manner is exactly in its place in imitations of chalk drawings, of which there are no better examples than Ryland's own in the fine Collection of Drawings published by Charles Rogers, as the two of St. Francis, after Carlo Maratti and Guercino, and many others. This work is entitled, 'A Collection of Prints in imitation of Drawings; to which are annexed Lives of their Authors, with explanatory and critical Notes, by Charles Rogers.' London, 1778; containing in all 116 prints, some of considerable size, of which 57 are by Ryland, besides the admirable mezzotinto portrait of Mr. Rogers at the commencement of the work. Among the imitations to his large, in various styles, the following are particularly worthy of note, either for their excellence or on account of their authors:—The Last Supper, by Leonardo Da Vinci; two drawings, by Michael Angelo, one of the tomb and the second of the grounds of the Church of St. Peter, after Berirocchi, and a third, the Tomb of Apolloionis; God the Father blessing the Creation, three young men naked, and another drawing, by Raphael; St. Francis, by Carlo Maratti; part of the Cupola of St. Peter's, by Correggio; some of the Executions of St. Peter, by Lodovico Carracci; Joseph and Jesus, and Caricatures of Painters, by Albani; Lot and his Daughters, St. Dominic presenting St. Catherine of Siena to the Madonna del Rosario,
St. Francis, St. Cecilia, and Chastity burning the Arms of Cupid, by Guercino; Bathsheba, by Boucher; Jacob persuaded to send Benjamin with his brethren into Egypt, by Veronese, and a Monk in his Cell, Rembrandt. Besides these there are drawings by the following masters:—Baccio Bandinelli, Battista Franco, Perino del Vaga, Bernini, Andrea Sacchi, Stefano della Bella, Borromini, Filippo Lippi, Guercino, Sacchi, the Counsellor, Parmigiano, Can. Francisci, an. Carracci, Schiöone, F. Mola, Elisa, Sirani, L. Cambiaso, S. Rosa, Jan Breughel, and P. Wouwerman. He engraved a few other prints also after P. di Cortona, Van de Velde, Ramsay, J. B. Oudry, and others.

RYSBRACK, MICHAEL. The date of the birth and the birth-place of this distinguished Flemish sculptor are differently given by different writers, but Charles Rogers, the publisher of the 'Century of Drawings,' &c., who was well acquainted with him, states that he was born at Antwerp June 24, 1693. He was the son of the landscape-painter Pieter Rysbrack, who, after he had given his son some instruction in design, placed him in 1706 with the sculptor Michael Walker Vorst, with whom he remained six years.

In 1720 Rysbrack came to London and distinguished himself for his small models in clay. He was the first sculptor who was extensively employed in England, and he spread a general taste for the art over the country by his fine monumental works. His progress in London was at first slow, and he gathered credit and notice, especially to the throne of the Earl of Shrewsbury. He was for some time engaged with Gibbs, who contracted with the original parties for monuments, for which he, on his part, contracted with Rysbrack, greatly to his own advantage. Gibbs, in 1724, undertook the monument of Lord Oxford, each for the statues on Prior's monument in the south transept (or Poet's Corner) in Westminster Abbey, while he gave Rysbrack only 35£. Rysbrack, however, soon became aware of his own merit, and shook off all dependence on Gibbs. Engagements crowded upon him, and there was not a work of sculpture of any consequence undertaken in England that was not entrusted to Rysbrack. When men found that the disposal of the funds of the most splendid monuments was in Rysbrack's hands, it created a great interest in his fame, and his reputation was long confined to great public monuments, though the study of his works is well worthy of attention.

In the reigns of Queen Elizabeth and King James I., a single figure reclining at length on the elbow in robes or serjeant's gown, was commonly overwhelmed and surrounded by diminutive pillars and obelisks of various marbles; and if particularly sumptuous, plaster busts and obelisks were also added. The handsome marble statue of Henry, the Duke of Newcastle, at Prince's Exchange, in London, is very tasteful. The Duke of Newcastle's statue in the Abbey, seems to have had an eye to that kind of tasteful expense. From the reign of Charles I. and James II. there are to be seen in Westminster Abbey, two statues of cherubines and flaming urns, generally satisfied the pietist of the time. Many of Rysbrack's stowed busts and bas-reliefs on those he decorated, but Sir Cloudesley Shovel's, and other monuments by him, made much of for love of beauty. One of these, the statue of Rysbrack, continues Walspole, 'taught the age to depend on statuary for its best ornaments, and though he was too fond of pyramids for back-grounds, his figures are well disposed, simple, and great.'

Rysbrack, unlike most of the artists of his age, studied exclusively nature and the antique; he had no respect for the works of his great countryman Rubens, and those of Rembrandt he would not look at, in which he was of course actuated wholly by the feelings of a sculptor, form and character being his exclusive study. He was the most industrious sculptor: fine works are to be seen by him in many parts of England, and in Westminster Abbey, at Stourhead, and at Bristol. In a few sculptor's workshops there has been more activity than there was in those of Rysbrack in Vere-street, Oxford-street, during forty years of the height of his fame. He worked in England through loyalty to his successful rivals Scheemaker and Roubillac, his occupation sensibly diminished.

Rysbrack's busts were very numerous, and include those of many of the great characters. His first public work was the bronze equestrian statue of William III., which was made for the city of Bristol, and erected in Queen's Square in 1735. Scheemaker also competed for this statue, and his model was accepted with 5£, though it was rejected for the design of Rysbrack, who received 3000£ for it; Walpole says 1800£. The monument to Sir Isaac Newton in Westminster Abbey, which was exposed in 1741, was executed by Rysbrack from a design by Kent. One to Mrs. Oldfield, in the cloisters of the Abbey, was presented the year before, was apparently his first independent monument in the Abbey.

In 1757 Rysbrack received a colossal statue of George II. for the parade of Greenwich Hospital, at the expense of Sir John Jennings, the then governor: it was cut out of a single block of marble weighing eleven tons, which had been captured from the enemy. It was also the statue of George II., which was in the old Royal Exchange, London. He obtained more however reputation by his monument to John Duke of Marlborough and his duchess in the chapel. At Blenheim-house, Rysbrack presented the model for the tomb of John, 2nd Duke of Marlborough, who died young, supported by Fame and History: in the lower part is a base-relief of the surrender of Marshal Tallard. At Blenheim also, in the library, is a beautiful marble statue of Queen Anne; it was erected in 1726.

In Christ Church College, Oxford, there is a statue of Locke by Rysbrack, which is in the 'Oxford Guide' erroneously attributed to Roubilac; it was made in 1737. This college contains also some busts of distinguished members by Rysbrack. Besides what has been already mentioned there are the following monuments by him in Westminster Abbey:—

1. To Admiral Vernon, and Richard Ken, governor of Minorca, in the north aisle; to John Friend, M.D.; and John Methuen, in the south aisle; to Sir Godfrey Kneller, in the nave; to John Gay, Nicholas Rowe, John Milton, and Ben Jonson, in the south transept (or Poet's Corner); and one to Daniel Fulleman in the cloisters.

The erection of Shakspere's monument by Scheemaker, in Westminster Abbey, is said to have greatly obscured the reputation of Rysbrack; but it only stimulated the industry of this sculptor to make still greater exertions. This dread rivalry was the cause of his making his Palladio, Inigo Jones, and Fiammingo, at Chiswick; and subsequently his masterpiece, the statue of the Hermitage in the north aisle, with the figure of Poet and Painter, by Mr. Hoare. This Hercules is a species of historical figure, a record of the English gymnasiaum or amphitheatre for boxing, an institution which was put an end to, as the principal gymnasts generally ended their career by being hanged. The figure was made for Henry Hoare, Esq., who built a temple expressly for it. It is of the heroic size, seven feet high, and cost Rysbrack three years' labour. The head is copied from the Farnese Hercules; the limbs are taken from several different English frequenters of this gymnastic amphitheatre. The arms, says Walpole, 'were Broughton's; the breast a celebrated coachman's, a busher; and the legs were those of Ellis, the greatest and greatest gymnatist.'

There are many other statues by Rysbrack—as a Flora, from the antique, at Stourhead; the Duke of Somerset, at Cambridge, presented by his daughter, in the possession of the Antiquary and Lady Gardiner; Duke of Coussac, a statue by Rysbrack, in his Duchess, in Salisbury Cathedral; Sir Hans Sloane, in the botanical garden at Chelsea, and his bust in the British Museum. Lord Elgin, Lord Goldsmith, Wits, Lady Booth, Leigh, Derby; the second, third, and fourth Dukes of Beaufort, at Badminton, Gloucestershire; Dr. Radcliffe, at Oxford; John Willet, Esq., Merly House, Dorsetshire; a statue of Charles I., for George Salway; and the following busts:—Pope, Gibbs, Sir Robert Walpole, Duke and Duchess of Argyile, Lord Bollingbrooke, Wooton the landscape-painter, Martin Folkes, Ben Jonson, Butler, Milton, Cromwell, the heads in the Hortzmance at Richmond, and those of the English Worthies in the Ellysian Fields at Stowe: he made also a good bust of himself. Notwithstanding his industry, Rysbrack was not rich, and when at the age of seventy he gave up his profession, he had no resources of his own. But the descendants of his effects—his remaining works and his collections of prints, pictures, drawings, marbles, casts, models, &c., including a large collection of his original drawings, which, says Walpole, were conceived and executed in one day of his life—though lamented by the ardent admiration of the last three years of his life was in making such drawings in bistre, and many were sold at the two auctions of his effects which took place after his death. He died January 3, 1770.

**Note:** The content appears to be a page from a book or a historical document, listing various entries that seem to be related to legal or historical references, possibly from a legal dictionary or a historical index. The entries are organized alphabetically with some entries indicating pages or volumes of a specific book or series (e.g., VOLUME II).
S.

SABINEA (named by De Candolle, in honour of Joseph Sabine, F.R.S., long time Secretary to the Horticultural Society of London), a genus of plants belonging to the natural order Leguminosae. It has a cup-shaped campanulate calyx, a four-angled and compressed staminal column, with an obtuse keel, rather shorter than the vexillum. The stamens are didaphous, the free one and four others half as short as the rest. The style is filiform, glabrous, and slightly compressed, linear, elongated, many-seeded, mucronate by the style. The species are unarmed West Indian shrubs, with abruptly pinnaed leaves, smooth mucronated leaflets, and one-flowered fascicled pedicels.

S. Florida has its leaflets in 8 or 9 pairs, elliptic oblong, the flowers rising before the leaves. It is native of the American Islands of St. John, Krabben Island, and St. Thomas. The violet flowers are considered poisonous.

S. dulcis has its leaflets in 10 or 12 pairs, elliptic obloneg, the flowers appearing after the leaves. It is native of Martinique and Porto Rico.

LIBERTY, FORA Medica: Don, Gardener's Dictionary.

SABINUS, MASSURIUS, a Roman jurist, a pupil of Aleius Capito, and the contemporary of Coccetus Nerva. He lived under Tiberius, but he did not die in that reign, as is generally supposed. He is mentioned in the passage of Gaius (t. 218) referred to Massarius Sabinus, of which indeed there can be no doubt. Massarius Sabinus gave the name of Sabinian to the school which he founded and to that of the Proculiani. [Roman Law, P. C. 6. 3. 9.] He was near fifty years of age when he was raised to the equestrian rank, and was in such poor circumstances that he was supported by the fees of his pupils (Pompon, Dig. 1, tit. 2, 4, § 47). It is said of him by Pomponius, 'par l'habile præsenis scripta' (he was the first who gave opinions publicly). Though the word is restricted in the modern editions of the Digest, the passage is quoted thus by Zimmerman: 'publicis scriptor.' It follows however from what Pomponius says, that with Massarius began the practice of giving written opinions, which were sealed with the seal of the jurist (responsa signa).

The reputation of Sabinus is shown by the publicity of his name, which was equivalent to the title of a great lawyer (Pergius, Sat. v. 90; Attian, Epist, iv. 5); and by giving his name to the school, of which his master Capito was considered to be the real founder. This is evidence of the greater originality and more enlarged views of Sabinus. His great work is 'Libri III. Juria Civilia,' from which there is no direct excerpt in the Digest, though there are various fragments in Gallus, iv. 1, 13, 18, 20, 21, 55, 56. The system is followed in this work has a great influence on subsequent writers. Pomponius wrote at least 56 Libri ad Sabinum, Gallus 47, and Ulpius 61. The arrangement of the matter of the work of Sabinus is confirmed by the order of the bands from the labours of his three commentators (Zimmermann, p. 313, n. 2).

The other works of Sabinus were—Commentarii de Indigenis, 'Libri Memoriale,' 'Fasti,' books of Responsis, a Commentary Ad Edictum, and 'Libri ad Vitellium.'

Zimmermann, Geschichte des Rom. Privatrechts; Index to A. Gallius, ed. Gronov. 1706; Grohues, Fine Juriscom. saltoresum.

SABINUS, CAELIUS, M., a Roman jurist, and the successor of Cælius Longinus. He was made Consul Designatus (Tact. Hist. i. 77); and his consulship belongs to the year A.D. 69, in which Otho and Vitellius became Emperors. He belonged chiefly to the time of Vespasian. He wrote a work, Ad Edictum Aedilicum Curulium, which is cited by other jurists (Gaius, Dig. 30, tit. 1, s. 90); but there is no excerpt from Cælius Sabinus in the Digest. He also wrote on other subjects (Dig. 35, tit. 1, s. 72, § 67). The extract in Gallus (vii. 4. Flileost servus, &c.) is probably from Ad Edictum, for Gallus in another passage (iv. 2) speaks of Sabinus as the author of such a treatise, though he calls him in this passage, according to some MSS., Cæcilis. He is often cited in the Digest simply by the name of Sabinus (Dig. 30, tit. 1, s. 14, 17, 65). The Cælius Sabinus is cited by Gaius in the Institutions (t. 70, 141).

SACCHAROLACTIC ACID. [Chemistry—Mucic Acid, P. C. S.]

SADI. [Saadi, P. C.]

SAFETY-VALVE. [Steam-Engine, P. C.]

SAGENOCRINUS, a genus of fossil crinoids. (Aust. & Forr.)

SAGENOPTERIS, a genus of fossil ferns. (Presl.)

SAGARABORDA, P. C. S.

SAHARUNPOOR, a district in the province of Delhi and presidential of Bengal, in Hindostan, formerly extended northward from the city of Delhi as far as the Serebic Mountains, which form the northern limit of the immense valley through which the Ganges flows. The Ganges and Jamna, north of the city of Delhi, run nearly parallel to each other at a distance of about 50 miles, and the district of Saharunpoor occupied the doss, or flat space, between them. The soil of the whole of this space is exceedingly fertile, producing grain of all kinds, sugar, cotton, indigo, and tobacco. Masjadee Sindia obtained possession of it in 1766, and it was held by the Mahratta king of Affar, and afterwards by the Maratha king of Satara, and is held to this day by the Bhopal king. In 1804 it was formed into two divisions, Northern Saharunpoor and Southern Saharunpoor, with a civil establishment for each; but this arrangement has been since modified, and the greater part of Southern Saharunpoor has been included in the district of Merut. Of the district of Merut, or Southern Saharunpoor as it is still sometimes called, the chief town is Merut, in 28° 59' N. lat., 77° 45' E. long. Of the district of Northern Saharunpoor the chief town is Saharunpoor, in 29° 59' N. lat., 77° 39' E. long., and about 90 miles, direct distance, N. by E. from the city of Delhi.

HAMITON, Zoil Indic Gemmaceae.

SAILORS. [Sails, P. C. S.; Sails, P. C. S.]

SAILS. Accidents involving serious loss of life and property are continually occurring from the inability of ordinary sails to resist violent gusts of wind. The sails of a ship [Sails, P. C. S. p. 318] usually consist of several widths of canvas sewn together side by side, with the seams arranged vertically; and the principal strength which they have to resist tearing arises from cords sewn along the edges of the sail. If these give way, or if from any accident a tear is commenced, the rupture frequently extends at once along the whole length of the canvas, and the sail is thereby, in nautical phrase, 'sailed away.' To provide a remedy for this formidable evil, Mr. Archibald Trail patented in 1844 an improved kind of sail, which, from their fitness to resist violent winds, he terms Storm-sails. These are made in the usual manner, and subsequently strengthened by sewing to their surface a number of canvas bands about an inch broad, with cords woven in them, such bands being secured at their ends into the bolt ropes, or cords forming the boundaries of the sail, and carried diagonally across the surface of the sail at an angle of 45° with the seams, and at a distance of about three feet from each other. Two sets of bands are used, crossing the sail in opposite directions, one set being attached on each side of the canvas; and the distance of the bands from each other is so adjusted with reference to the width of the canvas, that the points where the two sets cross each other may fall upon the vertical seams. By this simple expedient the strain is so equalised as to render tearing less probable than with an ordinary sail; while, if any injury be inflicted, the rent is confined within the narrow limits of one of the diamond-shaped compartments into which the sail is divided by the protective bands. In ordinary cases it is proposed to apply these bands not to new sails, but to such as are half-worn; and the patentee states that such sails may be thus protected at one-fifth of their original cost. Many naval men, after putting the invention to the test of experience, have testified their hearty approval; and it is suggested by some that its adoption may lead to the use of lighter canvas than would be safe with sails of the ordinary kind, with a view to lessening the cost of the handker, a circumstance of great importance in a gale of wind, while a saving may be effected in the cost of the canvas suffi-
cient to make the extra cost of the protection only one-ninth instead of one-fifth.

SAINT GEORGE, SAINT MARY, SAINT MICHAEL, Islands. [George, St.; Mary, St.; Michael, St.]

SAINT HILAIRE, GEOFFREY ETIENNE, was born at Etampes, in France, the 15th of April, 1772. He was destined by his father for the church, and received the appointment to a canonry in the twelfth year. He however, escaped the severities of the Nationality, and under him acquired a taste for the natural sciences. He first devoted himself to mineralogy, in which he published some of the most wonderful works. On coming to Paris he studied very diligently, and in 1793 was appointed subsecutor and demonstrator of the Natural History cabinet, in the Jardin des Plantes. He was subsequently appointed professor of natural history by the faculty of sciences in 1796. He was sent by the government on a scientific expedition to Portugal in 1808. In 1815 he was returned as a member of the Chamber of Deputies for his native city of Etampes. He died at Paris in July, 1828.

Geoffrey St. Hilaire was one of the most assiduous cultivators and ablest expounders of what is called philosophical anatomy. The idea on which this department of science was founded, he had in mind in his early works, and consequently applied to zoology and comparative anatomy during the latter part of the last century. It was however, amongst the rich collections of the Jardin des Plantes, and the activity and zeal of such men as Cuvier, Lamarck, Cuvier, Persoon, Valenciennes, Serres, and St. Hilaire, that it received its most important applications and its greatest development. The fundamental idea of this system is the unity of the composition, made up of various parts, and that all animals, and that this unity is capable of explanation in a few simple laws. What, in fact, might be predicated in botany of the various parts of a plant by a knowledge of the organization of the leaf, might, in the same manner, be predicated in zoology of the various parts of the animals, and a knowledge of certain fundamental parts of their organization. Thus Geoffrey St. Hilaire, amidst his other labours, established the fact that the numerous boxes of the head of the fish, and by consequence those of the higher animals, were transformations of the simple vertebræ; and that the laws of development which applied to the one applied to the other.

These views, equally applicable to every organ of the body, were generally developed by St. Hilaire in a work published in 1818, entitled 'Philosophie Anatomique,' which was illustrated with an Atlas of folio plates. He also published several papers and essays on the principles of philosophical anatomy. At the same time he published the lectures delivered on natural history in the Jardin des Plantes on the principle of the unity of organic composition, with the title, 'Sur le Principe de l'Unité de Composition Générale,' which had a wide circulation. St. Hilaire, it seems,&amp;#39; the morphological idea lying at the basis of philosophical anatomy had been applied to the explanation of the phenomena of abnormal forms of animals, just as it had been of plants, yet the subject had not been fully developed. In 1822 he published his great work on the anatomical philosophy of human monsters. These beings, which had formerly been regarded as mere unaccountable freaks of nature, were now found to be the result of the action of fixed laws, and under their various forms susceptible of the strictest classification. This work contained a new classification of monsters, with a description of and comparison of different forms, and a history of the various causes supposed to produce them. It also comprehended some new views on the nutrition of the fetus, and an accurate estimate of the phenomena attending the development of the embryo, and the development of the female fetus, in which the author pointed out the fact of a unity of composition in the reproductive apparatus of the sexes in birds and mammals.

A list of the works which St. Hilaire contributed to the various departments of natural history would be very long. There is scarcely a branch of zoology to which he did not successfully apply the great principles of his anatomical philosophy. His most important works were published during the present century, that do not bear testimony to the great influence he has exerted. At the same time the views held by the school, at the head of which Geoffrey St. Hilaire may be justly placed, have led to great controversy. Fully as Cuvier was impressed with the importance of Geoffroy's works, he opposed him in some of his conclusions, and this led to a controversy which developed, in the three inquiries, a theological question. Geoffroy opposed the doctrine of final causes, asserting in opposition to the the sensitive unity of composition. In his philosophy he states that he knows nothing of 'intentions' or 'objects' in creation; and when Cuvier spoke of the power animal and to you in nature, he rejoined that there were no 'animals which had the part to play in nature.' This controversy has recently, in this country, assumed a popular form; but it is obvious, from the use made by the Cuvierians of the principles of the 'philosophical anatomy,' that this theory is not incompatible with their views.

A complete edition of the works of Geoffroy, has been published in France under the title of 'Philosophical Works of Naturalists,' in 42 volumes. Etienne Geoffroy St. Hilaire has left behind him a son, Lidore, now Professor of Zoology at Bordeaux, and formerly at Paris, who has successfully cultivated the favourite science of his father.

Vol. II. -- 3 U
We must now present him exercising these quiet characteristics in a larger field, applying them to his conversion of causes, which differed from him in religious faith. The better to understand the peculiarly difficult nature of the mission with which he was intrusted it will be necessary to give some account of those persons. The city of Geneva had long ago pronounced the authority of its bishop and that of the Duke of Savoy; it was an independent republic and the stronghold of the Calvinistic party. It had become possessed of the ancient dioceses of Chablais, Lavaux, and Gailard; coincident with these changes was a substitution among the inhabitants of the creed of Calvin for the faith of Rome. In 1560, Charles Emmanuel Duke of Savoy, assiduously interested in this anti-Catholic portion of his duchy, and his first care was to attempt to bring back the inhabitants to their former religion. (De Thon, Hist. Univ., l. aclx.) For this purpose he applied to the titular bishop of Geneva, Claude de Grandier, to send missionaries over the conquered country. Francis de Sales, and his relation Louis, the canon of Geneva, were among the first to undertake an enterprise in the prosecution of which much opposition and some personal danger were to be apprehended.

On the 9th September, 1564, the two missionaries arrived at the frontiers of Chablais, where they dismissed their servants and equipment and determined to travel on foot, in order more easily to discharge to the example of the Apostles. The town of Tonon, the capital of the Chablais [Chablais, P. C.], which contained only seven Roman Catholics, was the first place in which they exercised their mission; the fruit of it was not abundant. On the fact of this Christmas-eve of 1567 eight hundred persons were admitted to the communion of the Eucharist in the church of St. Hippolytus in that town. But the most important object Francis had in view was the conversion of the bishops of the Calvinistic party. To this end he first solicited an interview with Theodore de Beza [Beza, P. C.], who was then fast sinking under the weight of age and infirmities; several conferences took place between them at the request of Beza, in the result of which that religious leader bowed down in obedience to the religious persuasion of the narrator. Whatever changes however took place in the mind of Beza through his intercourse with Francis, it is certain that it was accompanied by no public profession. [Michelet, without however citing his authority, remarks, that the Roman Catholic missionary added to his spiritual inducements the weight of temporal advantages, and made him an offer of a pension of 4000 crowns if he would conform to his church.] On the return of Francis to Annecy, in 1599, he was appointed coadjutor to Claude de Grandier, the bishop of Geneva, with the title of Bishop of Neapolis in particular indulgence, this being for a long time refused to accept, and only yielded on the earnest solicitation of the pope, Innocent IX.

In 1602 he visited the court of France for the purpose of obtaining permission from the king, Henry IV., to pursue his missionary labours in the territory of Gex, which had been given up to France by a treaty of peace concluded between Henry IV. and the Duke of Savoy. At the time which he preached in the chapel of the Louvre, is said to have created considerable sensation, and to have become the means of recalling several of the most influential of the Calvinistic nobility to a belief in their ancient faith. The king, desirous of retaining him in France, made him the offer of the first bishopric which might become vacant and the immediate enjoyment of a considerable pension. These offers however he declined, declaring that his chief wish was to be permitted to live and die among those whom Providence had intrusted to his care.

On his return to his native country, after a residence of nine months in France, as he was, by the death of De Grandier, a prelate who appears to have been worthy of so illustrious a colleague, appointed to the bishopric of Geneva. He prepared himself by a close retirement of twenty days at the castle of Chambesy, in order to this medium of retirement he framed for himself a rule of life by which he was in future to be guided; the details of it are given with elaborate minutiae by his biographers, and are so interesting a compilation of the conditions of his life that it suffices in itself the dignity of greater importance in the sight of God than the exercise of bodily mortifications or the display of an ascetic austerity. On the 8th December, 1602, he was consecrated bishop of Geneva. His bishopric was characterized by a reform of usage among the clergy of his diocese, and to reform various abuses which time had gradually introduced; these measures he chiefly effected by the issue of mandates in which he was the more vigorous by virtue of his new authority and Christian charity. In short, he showed himself a worthy disciple of St. Charles Borromeo, whom he professed to take as his model in the discharge of his episcopal duties. (Bosio, Hist. de Genève, v. 2, p. 215.) Francis de Sales then proceeded to France, where he was again successful in making converts. Several months after he hazarded the repeated offers of advancement from the French king, while at the time he gave proof of his consistency in declining the proffered honour of a cardinal's hat from the pope, Leo XI. In 1607 he was applied to by the reigning pontiff, Paul V., to express his opinions on the extent of the efficacy of Divine Grace on the free will of man. It was principally on this question that the Dominicans and Jesuits were divided (Black Flowers, P. C.; Jacours, P. C.). His answer is expressed with so much caution that it is difficult to discover from it his real sentiments; they are, however, more clearly shown in his other writings, especially in his treatise on the Love of God and how to attain it in the midst of a Religious Life", a book which still maintains a merited popularity. The style, though perhaps too full of metaphor for modern taste, is devoid of affectation, and breathes throughout a spirit of truth. From the general account given by Michelet, it is safe to find, as it were, living fountains springing up, flowers after flowers, rivulets meandering as in a lovely spring morning after a shower. It might be said that he amuses himself too much with a shower; that his method is no longer so strong as his shepherds guide, but such as would suit a flower-girl: as his Philotheso would say, he takes them all and takes too many; there are some colours among them badly matched, and have a strong tinge of the extrinsic; yet it is very different.

In 1609, Jean Pierre Camus was named Bishop of Bellay, and he wrote to the Bishop of Geneva to request him to perform the ceremony of his consecration. Between these two remarkable men, whose habits and dispositions were very dissimilar, the closest friendship ever after subsisted. It is to Camus that we are indebted for a most interesting work, 'The Spirit of St. Francis de Sales,' which, more than any other, develops the private excellences of the saint. The following year Francis founded a religious order for females, called the Order of the Visitations, and placed it under the superintendence of a pious lady, Madame de Chantal, sister of the Archbishop of Paris, with whose desire he concurred on his visit to Dijon. The fervent admiration of this lady for the qualities of the Bishop of Geneva, to whom she had intrusted the direction of her spiritual affairs, perhaps too impassioned a pity which she so frequently addressed him, and which may be seen in the collection published at Paris in 1650, have been malignantly dwelt upon by some who have hitherto held it libelous to ascribe to the persons of such men as Bossuet, Fenelon, and De Sales. The increasing infirmities of the Bishop of Geneva, arising from the constant application to the duties of his office, obliged him, in 1618, to seek for the assistance of a coadjutor bishop, and, at the suggestion of Cardinal Frederick Borromeo, his brother, John Francis de Sales, was consecrated to that charge with the title of Bishop of Chalcedon. In 1619 he accompanied to Paris the Cardinal of Savoy, to whom the mission had been intrusted of soliciting for the Prince of Piedmont the hand of Christina, sister of Louis XIII. On the marriage of this princess he was appointed her almoner, in an office of which he first declined on the condition that it should not be allowed to interfere with the discharge of his other duties. But the undiminished energy of such a spirit was too overpowering for so feeble a frame. In 1622 he retired to Chambesy, in order to rest, for himself or for it by severer mortifications and a closer communion with God. He preached for the last time on the Christmas-eve of that year; the next day he was seized with a paralytic stroke, and on the 10th of December, 1622, he died in the 59th year of his age, to the great loss of his subjects, of which his body was conveyed to Annecy, as his festival in the Roman calendar.
S A M

The claims of St. Francis de Sales as a devoted servant of the church have never been disputed, though they have been differently esteemed and represented. Humility and zeal were the two prominent virtues in his character, and it may be safely said that the former taught him to forget himself, the latter to be ever mindful of the wants of others. Between him and Fenelon a closer comparison might perhaps be made than with any other of his contemporaries. In the discharge of their pastoral duties they were alike successful, and by the use of the same means, a careful adaptation of advice to the temper and disposition of the advised. While, however, it must be admitted that Fenelon was a theologian, and St. Francis de Sales, Henri de Maupas, Bishop of Erreux, Le Pere Goul, Mad. De Bussy Rabutin, and the Jansenist Binet. See also Alban Butler’s Lives of the Saints; Moretti, Diet. Histoire de l’Eglise, ch. v. (Answered.)

SA M A R A. [SHIENK, P. C. S.]

SAMEN or SEMIEN MOUNTAINS. [ADYBIHA, P. C. S.]

SA M E N E S S or IDENTITY. This term is generally applied to what is called personal identity, or the sameness of a living and intellectual being, as man. There are some remarks on this subject by Bishop Butler in his 《Discourse of Personal Identity,》

The sameness of objects which are external to a man consists in the perception of a variety of circumstances as to these external objects and at different times, from which arises an opinion of sameness in a certain sense. A man sees a tree growing in a certain place, and he may have remembered it for many years. But in the mean time the tree may have increased a hundred-fold in bulk, and therefore its substance is not the same as that of the tree which he first saw there; and besides this, there may not be a single particle of matter the same in the tree at two remote times of his observation. The tree then is by the supposition not the same in a strict sense, but yet it is a real constant. A man may no more believe that all the change that the tree has undergone belongs to some other tree, than he can believe that the growth of his own body belongs to another being than himself.

When sameness is applied to a living and intellectual being, it includes both the matter of the body and something else. A man can have no doubt that his body is not entirely the same in youth, in middle age, and in old age. He can view his body as it does any thing external, and has a belief that it undergoes changes, and is therefore not the same in the strict sense. But yet he considers himself the same person; person herein including something besides the body, whether that something be a property of an organized body, or something else. ‘The ground of the doubt,’ says Locke, ‘is the supposition that the same person be the same substance, as well as the same substance, as that which the mind perceives of our existence, in youth and in old age, or in any two successive moments, is not the same individual action, i. e. not the same consciousness, but different successive consciousnesses.’ Butler’s answer to this vague talk is sufficient. But more may be said. How is consciousness of our personal identity, or if this form of words be objected to as a way of begging the question, bow is the thing called consciousness of our existence? at any two successive moments. Is not this a new consciousness of the same person, or the same consciousness of the same person, but different successive consciousnesses? What are successive moments in a man’s consciousness of his own existence? It is more consistent with that consciousness which we have to the belief that the consciousness of our identity is not the same, and the same; and if it is allowed that there is in man a belief that he is at different times the same being, in some sense which he cannot otherwise explain than that he feels that he is it follows that this consciousness of personal identity is one indivisible thing, that it is as continuous as the personal identity itself which it presupposes. Nor is it any objection to say that a man’s faculties are subject to illness, and he may lose the exercise of his reason and recovery; or an accident may befall him, which for a time renders his bodily and mental powers inactive, though he may finally recover his former state of health.

SAMOLUS, a genus of plants belonging to the natural order Primulaceae. It has a 6-parted calyx, its tube adhering to the lower half of the germen. The corolla is salver-shaped with a short tube and a 6-parted limb with interposed converging scales. The stamens, 5 in number, are inserted near to the base of the tube of the corolla. For capsules half covered by the persistent calyx, many-seeded, and opening with reflexed teeth.

S. volandallis, brook-weed, has obovate or roundish leaves, the upper leaves blunter with a short integument. The flowers are monocious, the calyx blist and 6-toothed, the style trifid, and the capsule 3-locu- cious. S. aucupariun is a tree 30 feet high, with ohlong lanceo-
late, acute, serrate leaves, with an intermixture of larger and rounder teeth, coriaceous, shining, and about 6 inches long. The spikes are terminal, lax, thick, green, and about 6 inches long; the male above, the female below. The calyx of both a dark purple. It is native of the woods of Carthage.

S. indicum has alternate stalked leaves somewhat pendulous, broad, lanceolate, serrate, smooth, and of a deep shining green, from 2 to 4 inches long, and broad in proportion; the stipules somewhat cordate and expanding. The filaments longer than the calyx, the anthers ovate. The female flowers at the base of the calyx often solitary. The capsule or not is globe-shaped, with a meagre, 6-valved, 6-seeded, and exceedingly hard. The seed is solitary, affixed by the apex, ovate, and smooth. The juice of this species, like the former, is highly poisonous.

(Loedii, Flora Medicai: Burnett, Outlines of Bot.)

SAPONARIA (from the Latin 'sapos', 'soap', so called because the bruised leaves are said to produce a lather like soap when agitated in water), a genus of plants belonging to the natural order Caryophylidae. It has a 5-toothed calyx naked at the base, 5 clawed petals, 10 stamens, and 2 styles. The fruits are red globular.

S. officinalis, soap-sor, has fuscated corymbose flowers, a cylindrical slightly downy calyx, retuse crowned petals, eliptic-lanceolate ribbed leaves, and an erect stem. It is native of many parts of Europe by the banks of streams, and in Britain, amongst grassy river sides and under hedges. The flowers are either single or double, of a rose or pink colour, seldom white. The double variety of this plant is esteemed as an ornament to the garden border, but is found inconvenient, unless planted in pots, from the spreading nature of the root, which extends under-ground like those of cough.

S. vaccaria has pinnuled flowers, pyramidal, smooth, fine-angled calyxes; membranous outer bracteae; ovate, lanceolate, scutelate leaves. It is native among corn in many parts of Europe, particularly Germany, Switzerland, and the Levant. It derives its specific name from the idea that it increases the lactic acid secret in cattle and sheep.

All the species of this genus are very ornamental. S. ocygnea is one of the most elegant plants we have in our gardens, and is well adapted for rock-work. It has red or pink flowers and is a trailing plant. A mixture of sand, loam, and peat is best adapted for all the species, and they are easily propagated by dividing at the root, or by seeds; the young cuttings taking root freely under a hand-glass.

(Doii. Gardener's Dict.: Thompson, Brit. Is.; Burnett, Outlines of Botany.)

SARCOSTEMMA (from σάρας, flesh, and στέμμα, a crown, in reference to the leaves of the inner corolla being flesh-colored by the natural order Apocynaceae. It has a rotate corolla, a corosnet of white stems; the outer one cup-shaped or umbrellate crenated, the inner one 6-leaved, higher than the outer one, with fleshy segments. The flower is nearly blunt and smooth, and the seeds cuneate. The species of the genus are natives of New Holland and the East Indies as well as of South America.

S. glaucum, glaucous-leaved Sarcostemma, is a lacticent smooth twining herbaceous plant. The leaves are lanceolate, short-stalked, slightly revolute, membranous, being with the midrib prominent on the under side, which is glaucous. The umbels are many-doubled between the petals, on very long peduncles. The segments of the calyx lanceolate, ciliated, and acuminate. The corolla white with a large fleshy similar wavy corosnet; the segments of the corolla fringed and purple.

S. Brownii is a twining glabrous plant, with lanceolate acuminated glabrous leaves, and interpetiolar umbels; the pedicels, calyxes, and corolla downy; the segments of the corolla and fringed and purple.

B (Loedii, Flora Medicai: Burnett, Outlines of Bot.)

SAROTHAMNUS, a genus of plants belonging to the natural order Leguminosae. It has a cupped calyx, the upper lip with 2, the lower with 5 teeth. The flower is long, conical, thickened upwards, and channelled within. The stigma terminal, capitulate, and small. The pod is flat.

S. scoparius, broom, is a species of the genus, is 6 to 8 feet high, angular, and glabrous. The leaves are terebinth or simple, the leaflets obovate. The flowers are axillary, solitary, or in pairs, shortly stalked, large, and of a bright yellow. The pods are dark brown, hairy at the base, and have numerous seeds. It is found on dry hills and heaths.

(Babington, Man. Brit. Bot.)

SARVINIUS, a name of several Roman jurists.

CLAUDIUS SARVINS, the name of a Roman to whom two Descriptions of Antoninus Pius are addressed (Dig. 20, tit. 5, s. 1, § 3; 50, tit. 7, s. 5); and a person of the same name was a person under the Divi Fratres, of the Pius Successors. He is generally considered to be the author of a work in a single book, 'De Poenis Paganorum,' which in the Florentine Index is attributed to Venuleius Sarvins. There is a single Excerpta in the Digest in the Digest of Sarvins (7).

QUIIIA SARTINUS is cited in the Digest (34, tit. 2, s. 19, § 7) as the author of a work 'Aedictum,' in ten books at least. Whether he is the same as Claudius or Venuleius Sarvins cannot be determined.

VENULEIUS SARTINUS, a Roman jurist, who is simply called Venuleius in the Florentine Index, though in the titles of the Excerpta in the Digest he is often called Venuleius Sarvins (Alexander Severus, 68) says that he lived under Alexander Severus; but there is some doubt about his period. His writings mentioned in the Florentine Index are, Ten Books of Actions, Six of Interdicts, Four of the Office of the Pagan Princes, Three on Publica Judaica, and Nineteen of Stipulaciones. The book De Poenis Paganorum has been already mentioned.

(Grolia, Vite Jurisconsultorum; Zimmern, Geschichte des Röm. Rechts, pp. 354, 379.)

SAURICHTHYS, a fossil genus of fishes from Amouth. (Agassiz.)

SAUROCEPHALUS, a fossil genus of fishes from the chalk series of England and America. (Hays.)

SAURODON, a genus of fossil fishes from the chalk series of England and America. (Hays.)

SAUROPSIS, a genus of fossil fishes from the olit and liss crania. (Agassiz.)

SAUUREA, a genus of composite plants belonging to the sub-order Caryocarpaeae. The fruits are all hermaphrodite and tubular. The stamens with ciliated setae at the base. They are common in the temperate zone, the racemose scaly. The pappus in 2 rows, the outer one consisting of short, rough bristles, the inner one feathery. S. alpina has a stem from 3 to 12 inches high, erect, the leaves finely downy, smooth, the underside of the heads with pinkish florets and purplish anthers. The leaves are nearly glabrous above, cottony beneath, the lower ones ovate lanceolate, the upper ones sessile lanceolate, all distantly-toothed, the heads in a dense corymb, the involucre sub- cylindrical, with depressed hairy scales. This is the only British species: it is found in alpine situations.

(Babington, Man. Brit. Bot.)

SAUSMAREZ, DE JAMES, ADMIRAL LORD, was born at St. Peter Port, in the island of Guernsey, on the 11th of March, 1757. His family name, De Sauzmarez, bears evidence of Norman extraction, and mention of it is to be found in the earliest records of the Channel Islands. From early youth he manifested a strong inclination for the naval service, in which several members of his family had distinguished themselves. When thirteen years of age he entered as a midshipman on board the 'Victory.' On the 17th of June he was commissioned in the 'Beds.' He afterwards served in the 'Narcissus,' 'Winchelsea,' and 'Levant.' He was afterwards appointed second-lieutenant to the 'Fortitude,' Ad-
mired Sir Hyde Parker, and he was in the engagement which took place on the 28th of June, 1782, while he was with the Dogger Bank, on the 5th of August, 1781. His behaviour in this action, in which he was wounded, caused him to be promoted to the rank of commander, and appointed to the command of the "Vengeance." In the month of December following, Captain Saumarez was ordered to place himself under the command of Admiral Kempenfelt who, with twelve sail of the line, was commissioned to proceed to the West Indies. He was reinforced by the Comte de Guichen, and which was destined to assist the Comte de Grasse in the capture of Jamaica. To inform Sir Samuel Hood, the English Admiral in the West Indies, of the arrival of these ships, and the probable importation, and Captain Saumarez was selected for this service. While at Jamaica he was enabled, through an exchange, to obtain post rank and the command of the "Russell," a ship of the line. In this ship he greatly distinguished himself at the memorable battle of the 12th April, 1782. [Hoon, P. C.; Rodkey, P. C.] On the 29th July following, he returned to the Russell to England, and from thence to his native island, where he enjoyed in the society of his friends the peace which was soon after proclaimed. On the breaking out of the war of the French revolution (January, 1793), Captain Saumarez was appointed to the command of the Crescent, of 36 guns, and of the fleet which was to proceed to Cherbourg, after a warm action of nearly two hours and a half, the French frigate "la Réunion," of 36 guns, but of larger size and with a much more numerous crew. This frigate had sunk the Crescent, but the French lost their Crescent had only one man wounded, and that by the recoil of a gun. The success of this action procured for him the honour of knighthood, and he was presented by the merchants of London with a valuable plate. In the month of November following, Sir James Saumarez was placed under the orders of Admiral Macbride, who gave him the command of a squadron consisting of the Crescent and Druid frigates, a brig, and a cutter: this was to assist the West India squadron under the orders of Captain Hood, to the joining of the Vondéans. On the 5th of June, 1794, an opportunity was presented him of displaying his skill and intrepidity; while proceeding from Plymouth to Guernsey with the Crescent, Druid, and Enterprise frigates, he was attacked by a French squadron of more than double his force. A running-fight ensued, the brunt of which was borne by the Crescent and the Druid, to cover the escape of the Enterprise, which, on account of its inferior sailing, ran considerable risk of being captured. This object being effected, he closed in with the enemy in the Crescent, and thus enabled the Druid also to take refuge into the roads of Guernsey. He effected the escape of the Crescent by his cool intrepidity and a perfect knowledge of the difficult coast in which he was engaged. As soon as the other ships were secure, he bore up as if to run the Crescent on the rocks to avoid the enemy. The boat of signal was sent in, in order to steer through a narrow passage between the rocks, which had never before been attempted by a ship of her size; he thus reached in safety an anchorage where he was enabled to defray his own expenses and that of the family. In March, 1796, Sir James was appointed to the Orion, 74, and placed under the orders of Lord Bridport, in which ship he opened the memorable battle which took place on the 23rd of June. In 1797 the Orion was attached to the squadron sent to reinforce the fleet of Sir John Jervis off Cape St. Vincent, and took a prominent part in the glorious engagement with the Spanish fleet. [Jervis, John, P. C.] He was, after this battle, employed till the end of April, 1798, in the blockade of Cadiz, and then selected by Lord St. Vincent to join the squadron under Sir Horatio Nelson destined to join with the Otho Fleet under Admiral Byron, of Toulon. At the important victory of the Nile, Sir James, as senior captain, was the second in command, and his ship was the third which entered into action; the courage which he displayed shone with especial brilliance. Having been deputed to save the remnant of the unfortunate crew of the Orient. [Nelson, P. C.] A wound which he received during the action was so severe as to prevent his leaving the Orient on his return. On the 14th of February, 1799, Sir James Saumarez was promoted to one of the vacant colonels of marines, and to the command of the "Crescent," a ship of the line, and of the duty of the Channel fleet, under Sir Alan Gardner, to bring home from Lisbon the ships captured at the battle of the Nile. During the winters of 1799 and 1800 he was entrusted with the command which was destined to watch the French fleet in Brehat. The difficulties to be encountered in this arduous service, particularly during the winter season, were very great; and it is no small praise to the careful vigilance and perseverance of the squadron, that during the whole time he remained on that station, not a single vessel sailed from or entered the port of Brehat.

At the commencement of the year 1801, he was promoted to the rank of rear-admiral, and was ordered to the West Indies, under the orders of Admiral Lord Hood. On the 12th of June following was appointed to the command of a squadron to watch the movements of the Spanish fleet at Cadiz. On this occasion he was created a baronet. On his arrival at Cadiz, information was given to him of the number of the enemy's ships and frigates, and his squadron of that date was composed of the Crescent, a frigate and a frigate were in the bay of Algiers, and he immediately determined upon attacking them. The position of the French was one of great strength, defended by the batteries in the bay and fourteen large gun-boats. The action commenced on the morning of the 6th of July, in which he had the misfortune to lose the Hannibal, 74, which accidentally grounded, and, after a long and sanguinary engagement, Sir James found himself compelled to repair to Gibraltar. The failure of his first attack on the French fleet did not discourage him. Expecting that the enemy's squadron at Cadiz would make use of the first opportunity which the weather might offer, to render the Nile, the French alone were seen steering for Algiers, with a squadron of not more than half the strength of the enemy; the admiral determined to attack them, for the purpose of preventing their return to Cadiz, and, on the 8th, sailed out to meet them. The enemy formed their line-of-battle off Cabrito. Shortly after the commencement of the engagement two of the enemy's ships were discovered to be on fire, and about midnight blew up with a tremendous explosion. The wind was at daylight to the Venerable, Captain Brenton, the disabled state of the English ships, and the sudden falling of the wind, prevented the admiral from attaining his object, which was to prevent the French and Spanish re-entering Cadiz; they did so, however, with the loss of three sail of the line, and upwards of 2000 men, blown up, killed in action, and taken prisoners. An important result of this victory was the preservation of a large fleet of British merchants, which was the object of the French to seize. A most unfounded imputation has been attempted to be cast on the military character of Sir James Saumarez by a well-known modern French historian, who has asserted that, contrary to the rules of war, a red-hot shot was used by him in that engagement, and that it was owing to these means that the burning of the Spanish ships occurred. This assertion has been indignantly refuted by the concurrence of several officers who were present at the action. The admiral was rewarded by receiving the Order of the Bath. On the meeting of parliament, a motion made by the Earl St. Vincent, and seconded by Lord Hood, was carried, in which Sir James received the thanks of the House for his gallant conduct in his late actions with the combined fleets of France and Spain. Lord Nelson remarked that "a greater action was never fought." The thanks and freedom of the City of London were also voted to him, with a valuable sword. At the peace of Amiens, Sir James Saumarez returned to England, and, in 1803, a pension of 1200£ a year was conferred upon him. On the renewal of hostilities, he was appointed to the command of the Crescent, which he held until 1806, when he was promoted to the rank of second in command of the Channel fleet under Earl St. Vincent. On the breaking out of the war, he was commissioned with the important command of the Baltic fleet. He there displayed considerable diplomatic talent, and, by his firm but conciliatory conduct, he was powerfully instrumental in deterring the Russians from a fresh approach to the North Sea. His policy he pursued towards the Northern States has been clearly detailed by his imperial biographer Sir John Ross in the work referred to at the end of this article. As an expression of gratitude for the services rendered to Sir James Saumarez, the Grand Cross of the Military Order of the Sword was conferred upon him by the king, Charles XIII. His influence with the king of Sweden was also the chief means by which the neutrality of Sweden was preserved on his association of Marshal Bernadotte as crown prince. [Charles XIV. of Sweden, P. C. S. P.]
The changes which took place in the aspect of affairs on the Continent having rendered the presence of a naval British force in the Baltic longer necessary, Sir James was recalled, and his recall accompanied by a letter from the Lords Commissioners of the Admiralty, in which they expressed "their marked approbation for the zeal, judgment, and ability evinced by him during his late command."

At the peace of 1814 he was raised to the rank of full admiral; on the visit of the allied sovereigns to England he received their personal thanks for the services which he had rendered to their cause, and, having accompanied them to Oxford, he obtained the honorary degree of Doctor of Civil Law. In 1819 he was appointed rear-admiral, and in 1821 viceroyalty of Great Britain. In 1834 he was preferred to the command of port-admiral of Plymouth, which he held till 1827, and with it may be said to have closed his professional career. At the coronation of William IV. in 1831, he was raised to the peerage of the United Kingdom, with the title of Baron de Saussure, of Saussure, in the island of Guernsey—a reward which his long and important services had merited, and which it was expected he would have received at an earlier period. He was shortly afterwards made general of marines, and in 1834 an elder brother of the Trinity House. In the same year he was presented by the King of Sweden with a full-length portrait of himself, accompanied by a most gratifying letter, which showed that time had not effaced from the mind of the king the services rendered by Lord de Saussure to Sweden. The remainder of his life was for the most part spent in the enjoyment of quiet and repose on his country estate in Guernsey. His religious and charitable affections had endeared him to his countrymen; and his death, which occurred on the 9th of October, 1836, was lamented as a public loss. He was succeeded in his title by his eldest son, James, the present peer, who is in holy orders.

Savings' Banks. The 5th and 6th Wm. IV. c. 57, passed in September, 1835, extended the provisions of the 3 Geo. IV. c. 29, and of 3 Wm. IV. c. 14, to savings' banks in Scotland, and enabled existing banks to conform to the said acts by preparing and depositing their rules pursuant to these acts.

Military or Regimental Savings Banks were established by warrant dated October 11, 1843. The following is the amount of all sums deposited in them within the year ended March 31, 1844; of all sums withdrawn during the same period; and also of the number of depositors on the 31st of March, 1844:

On the 9th of August, 1844, the royal assent was given to an act entitled "An act to amend the Laws relating to Savings' Banks, and to the Purveyance of Government Annuities through the Medium of Savings' Banks."

The first clause of this act reduces, from and after the 20th of November, 1844, the interest of all moneys invested by the trustees of savings' banks in the national funds, to the rate of 3½ per cent.; and s. 2 declares that the maximum of interest to be allowed to depositors shall not exceed the rate of 3½ per cent.

From the same date every depositor, on making his first deposit (s. 3), shall sign a declaration as provided by previous acts, a copy of which is to be annexed to the deposit-book; and on the back of the receipt this book is to be produced at the institution for the purpose of examination.

Any party, estate, or other person holding a situation at a savings' bank (s. 4), receiving deposits and not paying over the same to the managers of the bank, is declared guilty of a misdemeanour; but no trustee or manager to be liable (s. 6) for any deficiency unless they have declared in writing their willingness to be so responsible, and this responsibility may be limited, and with respect to cases of money actually and personally received by them.

When deposits are made in trust for another (s. 7), the sum is to be invested in the names of the trustees and the person on whose behalf it is made repayments not to be made without the receipt of both, or of their trustees, executors, or agents appointed by power of attorney.

Annuitants under the 3 and 4 Wm. IV. c. 14, are not to exceed 6½% a year in the whole, but separate annuities to that amount may be granted to a husband and wife; but instead of the charges under the former act, the charges are to be now (s. 9), for an annuity under 5½, the sum of 5½; 6½ and under 10½; 10½; and under 14½, 14½; and over 20½, 20½; and over 30½, 20½; and not exceeding 30½, 90. Where deposits exclusive of interest do not exceed 60½, (s. 10), if a will or letters of administration are not produced within a month, the money may be paid to the widow, or the person entitled to the effects of the deceased; if a depositor be illegitimate and die intestate, the managers (s. 11), with the consent of the public, and with power to appoint a manager to collect the debts. The time for issuing the half-yearly receipts for interest is extended (s. 13) to sixty days from and after the 20th of May and 20th of November; and the time for transmitting the annual statement is extended to nine weeks after the 20th of November in each year.

Any dispute between the depositors and the managers is to be settled (s. 14) by arbitration of the barrister appointed under the previous acts, who shall have power to determine any claim; and the barrister is empowered for this purpose.
(e. 15) to inspect the books of the institution, and to examine
witnesses on oath or affirmation: false evidence to be punished as
perjury.

Bonds given as security under previous acts (9 Geo. IV, c. 92,
and 3 & 4 Wm. IV, c. 14) are to be deposited with the
Commissioners for the Reduction of the National Debt (s. 10),
to secure the payment of the annuities, or any other sum
necessary for the purposes of the establishment, to the
trustees and three managers when required to be cancelled.
Every officer trusted with the receipt or custody of money
(s. 17) is to give sufficient security, such security, when
given by an executor, assignee, or receiver of a se

lary, shall be by bond, which is exempted from stamp-duty.
The direction for depositing the rules of a saving's bank
with the clerk of the peace (s. 18) is repealed; but two
written copies of the rules are to be certified by the
barrister for his certificate, who, on approval, is to
return one copy to the institution, and transmit the other to
the commissioners.

Payments to the relations of intestate depositors (s. 20) are to
be made to the next of kin by the law of Scotland, in the
case of deposits in that country.
The act is declared (s. 21) to extend to societies for pur-
chasing annuities as well as to saving's banks, and (s. 22) to
Great Britain and Ireland, Berwick-upon-Tweed, Guernsey,
Jersey, and Isle of Man.

SCABIOSA (from scabies, the Latin word for scab or itch, which
diskourge the common or net is said to cure), a genus of plants
belonging to the natural order Dipsacse. The inner calyx
consists of 5 bristles, the outer one is membranous and plaited.
The receptacle scale. The fruit nearly cylindrical, with 5 to 7
seeds in 4-6-8 wall, variegated, convoluted. The species are perennial or suffrutescent herbs with visible leaves.

S. suaveolens, Devil's-bit, has an abrupt root appearing as if it
were buried in the earth; at the end, the heads of the flower
and fruit nearly globose, the outer calyx hairy, 4-5-6 leaf, the lobes
ovate acute, the inner calyx consisting of 5 bristles. Tho
corolla is 4-5 leaf, the lower leaves toothed, the upper ones
entire. The stem and both sides of the leaves hairy or glabrous.
The flowers are white, blue, violet or purple, varying in

SCAPHITES, a remarkable cephalopodous fossil genus, irregularly
convoluted at both ends, and occurring in the lower parts of the cretaceous system. (Parkinson.)

SCAPHODUS, a genus of fossil fishes from the outie of
Stonesfield, (Anglin.)

SCARLET FEVER. [Scarlatina, P. C.]

SCARLATTI, RIGHT HON. SIR JAMES, LORD
ABBING, was a native of Jamaica, where his family was
wealthy and of long standing. He was the second son of
Robert Scarlett, Esq., and was born in or about the year
1760. His mother's name was Elizabeth Anglin. The fa
culty estates went, it may be presumed, to the eldest son;
a third son, who also remained at home and followed the pro
fession of the law there, became Sir William Anglin Scarlett and
Chief Justice of Jamaica, and died not long ago after having
held that office for many years; James was at an early age
sent to England. Having finished his elementary edu-
cation, he, was, about the year 1786, entered a Fellow Com-
mone at Trinity College, Cambridge; and he was also, a
year or two after, admitted a student of the Inner Temple.
He took his degree, B. A. in 1784, and was called to the Bar
8 July, 1791; and graduated M. A. in 1794. His suc
cess at the bar was very decided from the first, and every year
added to his reputation and his emoluments. It was soon
found that he was a man of inestimable value to the bar,
being able to make such a large proportion of verdicts. Even while he was
still a junior counsel, he was very frequently entrusted with the sole conduct of important cases. At last, in 1818, he re
ceived a silk gown, and from that date he was recognized as the leader of his circuit (the Northern), and as occupying also
a foremost place in Westminster Hall.

He had made an attempt to be returned to parliament for
the borough of Lewes at the general election in October,
1812, but was defeated by Mr. George Shiffer, who was
brought in, as second member, by a majority of 164 to 164;
and he failed also in a second attempt on the same borough
when a vacancy was occasioned in 1816 by the death of the other
member, Mr. T. R. Kemp, being then defeated by Sir
John Shelley. He was first introduced to the House of Commons in 1818, as one of the members for the city of Peterb
ough, under the title of Sir James Scarlett. He did not, however,
make a figure in parliament corresponding to his eminence at the bar; nor was he a frequent speaker, although
he both supported Sir Samuel Romilly and Sir James Macin
tosh in their efforts to mitigate the severity of the criminal law,
and also occasionally took part in debates on financial subjects.
He was returned again for Peterborough at the general
election in 1830; but he resigned his seat in 1832 to stand
for Cambridge University. In his writings he speaks of the
constituencies of the House of Commons, and in terms which it
implies that they were then alive. Septimius Severus, afterwards
emperor, and Fabian, were pupils of Cerridvus, who pro
vided for them a capital education; but these great men did not belong to the Roman nation. See Saccus, in the article of
section iii; but his opinions gradually assumed more of a

(Dig. 17. tit. 1, s. 62); but the facts on which the opinion
is given are clearly stated. His style has been blamed as
false and inaccurate; but these qualities of his great capacity, and he left a name behind him.

There are excerpts in the Digest of Justinian from his
forty books of Digesta, six books of Responsa, twenty Libri
Responsorii, and three books of Quaestiones, the latter pub-
lict tractaturn, probably a book of decided cases.
The Florentine Index also mentions a single book 'De
Quaestione Familiar,' but there is no excerpt from it in the
Digest. There are only 217 excerpts from the writings of Scac
vola in the Digest.

Many of the Responsa of Scaevola appear twice, both in
the Responsa and the Digesta. Conrabi, followed by Blume,
who supposes that the former contains a final edition of
the facts which are briefly indicated in the Responsa, and wcre
a kind of commentary to the Digesta. Puchta says that the
passages in the Digesta do not show this; and that this rela-
tions is rather that of the Quaestiones to the Responsa: 'the
Quaestiones were devoted to the complete examination and
justification of the opinions.

Clausius Tryphonius and Paulius commented on Scaevola;
and he is often cited by Marcianus, Tryphonius, Ulpius,
Paulus, and Modestinus. Scaevola commented on Julian and
Ulpius Marcellus.

Conservative complexion, and when the new Tory or mixed administration of Canning came into power in April, 1827, Mr. Scarlett, having been again returned for Petersborough at a general election, obtained the office of attorney-general. He was at the same time knighted. Having been once more returned for Petersborough he held his place throughout the administration of Lord Grey; but was succeeded in the Charles Wellington when the Duke of Wellington became premier in January, 1828; but was re-instated in May, 1829, upon the dissolution of Sir Charles for his opposition to the Roman Catholic Emancipation Bill; and, having declared himself in the late general election in 1830, he remained attorney-general till the accession of the Whigs in November of that year, when he was succeeded by Mr. (now Lord) Denman.

At the general election in May, 1831, Sir James Scarlett was returned for parliament for Cockermouth. At the next, which took place after the passing of the Reform Bill, in December, 1832, he was returned, after a contest, for Norwich along with Lord Stormont (now Earl of Mansfield). When this parliament was dissolved in December, 1834, on Sir Robert Peel being appointed premier, Sir James Scarlett was made Chief Baron and also the title of Baron Abinger, of Abinger, in the county of Surrey, and of the city of Norwich.

Lord Abinger died of a sudden attack of illness at Bury St. Edmunds, on the 20th of April, 1844. He had been twice married; first in August, 1792, to the third daughter of Peter Campbell, Esq., of Kilmorey, in Argyllshire, who died in March, 1829; secondly, in September, 1810, he married, as his third wife, Lady Sarah St. Jones, a sister of the Right Rev. R. J. Ridley, of Ockley. By his first wife he had three sons and two daughters, by the eldest of the former of whom he is succeeded in his title and estates. His eldest daughter married Mr. (now Lord) Campbell in 1821, and was created a peeress in 1856 by the title of Baronesse Stratheden.

Lord Abinger was a skilful and dexterous rather than an eloquent lawyer, and while on the bench he was more distinguished for the clearness with which he summed up a case for the jury than for the profoundness or subtility of his legal views. Yet he was considered also a sound and good lawyer. In the great art of gaining verdicts he was unrivalled; and no practitioner at the bar had ever before received so large a sum in fees in any year as he drew in the height of his practice. His conduct as attorney-general under the Tories in 1829, when he filed a number of criminal informations against the opposition newspapers, naturally exposed him to some severe animadversions from those who still continued attached to the more democratic political creed which he had originally been accustomed to profess.

SCHNECKEL, CARL FRIEDRICH, in the opinion of his own countrymen the great architectural artist of his age, and whose name has obtained European and permanent celebrity, was born March 15, 1781, at Neuppin, in Brandenburg, where he was 'super-intendent.' When only six years old he lost his father, and was taken to the care of his uncle, a merchant, in the 'Gymnasion' of his native town, where he remained till the age of fourteen, when he removed to Berlin. Soon after arriving there he obtained employment as an assistant to a pupil of the elder Gilly (David Gilly, born 1744, died 1800), a clever practical man in his profession, and author of several works on subjects relating to it. Hardly could he have been more fortunately placed; for about a twelvemonth afterwards, the younger Gilly (Friedrich) returned from his travels with an imagination warmed by his recent studies, and from him it was that Schinkel derived his best instruction, and together with an ardent relish for his art, more liberal and enlightened idea of its powers as a fine art than were generally entertained in those days, when a system of mere routine both in theory and practice prevailed almost universally. Friedrich Gilly and the young Schinkel, who was ambitious of elevating architecture to the level of the other arts of design, and to bring it into immediate contact with them, whereas it was then, and perhaps now, is too much regarded as one entirely apart from painting and sculpture, wished that Gilly himself would have achieved in his profession can only be conjectured, for he died within two years after his return, August, 1800, before he had completed his thirtieth year, leaving Schinkel to inherit the name that might else perhaps have been divided between them.

Although so young, Schinkel had been instructed by Gilly to superintend the execution of some of his buildings, and after his death Schinkel carried on the embellishment. Having required such proficiency in practice it would not have been
difficult for him to have adhered to that course under the
profession; but he preferred pursuing his theoretical and
analytical studies; during which time he turned his exercises in
them to account. He afterwards published various ornamental
articles for modellers, metal-workers, and other artisans of that
class. Out of such earnings he laid by sufficient to enable him
established schemes for a pilgrimage to the
' holy land of art.' In 1803 he set out for the
Dresden, Prague, and Vienna; and after extending his route to
Naples and Sicily, returned to Berlin in the spring of 1805.
But there in a period of two and a half years he was at that
time engaged in something that was to be considered as
prestigious to art, more especially architecture, to which the
state of public affairs in 1806 and following years threatened a
complete stoppage. He turned to landscape-painting, there-
fore, as an occupation, making use of the special views of scenery
which he brought home from Italy, and embellishing
his compositions with architectural accessories, or else
making the architecture the principal and the landscape the
accessorial portion of the subject. One work of note and
which gained him distinction with the public was a large
panorama of Palermo; and he also designed for the theatre
many acts of scenes, a collection of which, including those for
the Zauberflote, Die Braut von Messina, &c., were after-
wards published in a series of coloured engravings, whereby
they are rescued from the usual fate of similar productions of
the pencil. His various artistic labours during this period were
of the greatest consequence to him; for they helped him
call forth and exercise those two faculties in which those who
are otherwise able architects are generally deficient—
taste and imagination. Even had they been serviceable to his
own necessities, they were of service to the public in
recommendating him to the king, who, as soon as restored tranquillity
in public affairs permitted him to turn his attention to the
improvement and embellishment of his capital, began to em-
ploy Schinkel on those subjects which have a new aspect on
Berlin, and conferred on it a high architectural char-
ter. One of the earliest commissions of importance which he received from the king (who was then at London with the above-mentioned) was to join the collection of a national character intended to commemorate the pacification of Europe; but
though the architect's ideas excited great admiration, the
scheme itself was dropped. Whatever the disappointment may
have been at first, he had no time to dwell upon it; for from
the period of 1815 he was incessantly and most actively en-
aged. Among his earliest buildings were the Hauptwache,
Theatre, and Museum at Berlin, all of them treated in a pure
Heinrician style—a style which had only been hinted at in
such previous attempts at correct Grecian architecture as
Langhans's once celebrated Brandenburg Gate.' The façade
of the Museum more especially displays, together with severe simplicity of form, a decided tendency to and unthought of for any previous modern example which is
called Greek. The external elevation consists of merely a
single line of eighteen columns in ants (Erechtheum Ionic)
round a centre story on a flight of steps, enclosed by podestal walls (in continuation of the stylobate) and forming the ascent to the colonnade. Taken by itself, however, there would be nothing very remarkable in the general idea, whereas an extraordinary degree and kind
also of variety and effect are given to the whole by the inner
elevation or background behind the outer row of columns;
which presents in the centre portion of it a second colonnade
(four columns in ants), with a screen-wall rising about half
its height, and above and beyond that the upper part of the
open staircase, whereby the whole composition ac-
quires singular movement and play both of perspective and light
and shade. In which the wall forming the rest of this inner elevation, instead of being left a blank surface, or nearly
so, is completely decorated from top to bottom, or rather was intended to be so, the upper division of it on each side
of that inner colonnade being to be filled up by a single
large fresco, the cartoons or designs for which were prepared
by Schinkel himself, and have been extolled as masterly com-
positions. There is reason, however, to suppose that either the artist or his disciples, who have been more or less being spoken of as the artist to whom the task is to be con-
fided; and only when the frescos shall have been added, will
Schinkel's idea and the effect contemplated by him for the building be fully executed. Neither is there the least
mention of any of his works which have not been completed—not yet, at
least, according to his designs; for the two other buildings
above mentioned have not received their full complement of
sculpture, which, though it may be dispensed with for them as structures, is essential to them as works of architecture. It
is fortunate, therefore, that in any case we have Schinkel's
own ideas exhibited to us in his 'Entwürfe,' an unusually full
and extensive series of designs for all his principal buildings,
some of which are illustrated and explained far less sparingly
than is the custom in similar collections; for besides orna-
mental details, many of them strikingly original as well as
tasteful, perspective representations of the different parts of
the building and of the different ones of the same building are given; besides which, the engravings themselves are illustrated by the information contained in the letter-press. The publication of his designs contributed
nothing to the task of reading Schinkel's fame much more
rapidly than it would otherwise have been the case; and
it is one that forms a very complete gallery of his unusually
timorous, many and less varied architectural productions. With such ready materials, a descriptive catalogue of hisuildings might be easily drawn up, but we can merely mention a few of them: the Werder Kirche (Gothic), Bauschule, and Ob-
servatory, at Berlin; the Theatre at Hamburg; Schloss
Krescowice, Charlottenhof, and the Nicolai Kirche at Pots-
dam, which last would have been a most imposing structure
had the design been carried out, instead of being cut down
altogether by the omission of the cupola. His 'Entwürfe'
also contains his design for the Sing-Academie at Berlin—one
of his happiest ideas, which was unfortunately set aside for
that by Ottmer [OTTMERS, P. C. S.]; and six several designs for
a monument to the Great, in which he gave free scope to his imagination, and indulged in luxuriant archi-
tectural pomp. Another publication, entitled 'Werke der
Höeren Baukunst,' gives us a series of designs by him for
the now extinct Academy at the Palais at Amsterdam, the
Acropolis, forming an irregular assemblage of courts, colon-
ades, and buildings, some of which, especially one magnifi-
cent saloon, would have been marked by originality of
character as well as by strict adherence to the Greek, in
which his design was much superior to that by Klenze, which
is also published among those of the latter architect's; but, as
has been said already [ATHENS, P. C. S.], neither of them was adopted.
Another remarkable work of Schinkel's, his last one, not
his least poetical conception, was a design for a summer
palace at Orlanda, in the Crimea, for the Empress of Russia,
surrounded by terraces and hanging gardens on a lofty
eminence, commanding a prospect of the Black Sea. That
was in 1839, the same year in which was conferred upon him
the highest rank in his profession—that of Ober-Landes-Bau-
director; but it was to him a mere honour, for his career was
closed; his health immediately after the event had given
way, and in the autumn of the following year, on his return from
the baths, by whose waters he had hoped to be benefited, he was
attacked by an organic affection of the brain, which reduced him
to a state of almost unconsciousness; and his eyesight,
were somewhat impaired, his memory, and in that deplorable condition he remained upwards of a twelvemonth, till released from it by death on October
9th, 1841.

Schinkel has been called by some of his countrymen the
Luther of Architecture; and he certainly gave a fresh impulse to all
his work; and if he himself did much, his example and in-
fluence have perhaps accomplished more; for by venturing to
think for himself, he has led others to do the same. Yet with
all his freedom and originality, he was, perhaps, rather too
timid than too bold in his reforms, adhering in many respects
to the strictest letter of Greek examples, par-
sicularly in regard to the orders. As to Gothic, it would have
been better had he abstained from it entirely, and given his
undivided attention to the other style, first efecting and then
maturer new ideas from it. With all his invention, too, he
exercised none rather than the others in the light and airy
windows, for which he repeats the very same design again
and again in different buildings.

Schinkel has been made the subject of biographical notice
and of criticism more than any other modern architect. Of
two separate publications relative to him, one entitled
'K. F. Schinkel, Eine Charakteristik,' &c., 1842, is by Dr.
Kugler; the other by O. F. Gruppe; and both of them have
portraits of him, both by himself, and in different positions;
the latter represent him in his usual dress, and with his hat
on, and therefore conveys a better idea of his personal ap-
pearance.

Vot. II. — 3 X
C. between 1812, Le (The small S and ' traced review collection Frederic Romanism Among the tember, Heine early his the French. models for Weimar, 3 1767, intrusted with his name to an edition of Virgil. For some years Schlegel lectured at the university of Göttingen: his contributions to Bürger's ' Akademie der Sciences (especially on his poem on La Licorne,' and his essay on Dante), and to Schiller's ' Musen-Almanach' and 'Horen,' especially his translations from Dante with com- ments, secured him an honourable rank among the best writers of Germany. In 1816 he published the first volume of his translation of Shakespeare. In the same year he was appointed professor of Humanists in the university of Jena, and continuing his literary activity he soon placed himself among the leaders of German literature. He remained at Jena till 1802, a friend of Schiller, and an admirer of Goethe then at Weimar, who, however, did not return the sentiment. Pushed by ambition, Schlegel left the little town of Jena, and repaired to Berlin, where he gave public lectures to a mixed but highly intelligent public on literature and the fine arts. He remained there till 1806, having meanwhile imbied that puerile passion for little court distinctions, titles, and crosses, which in later years proved such a severe drawback on his real merits. Among the specimens of his literary activity in the period from 1797 to 1805, may be mentioned, besides the continua- tion of Shakespeare, his translation of the 18th grade of the Periander, a critical review, which he edited with his brother Frederic, and which did a great deal of good towards purifying the taste of the public; ' Gedichte' (Poems), Tübingen, 1800; 'Athen &um,' a book which he edited with the success and in which he first betrayed his growing tendency towards Romanism and mysticism; 'Vorlesungen über Literatur und Kunst des Zeitalters,' (Lectures on the Literatur and the Fine Arts of the Age), which appeared in the 'Europe,' a review edited by Frederic Schlegel. In 1806 he made the acquaintance of Madame de Stael-Holstein. Surprised at finding so rare a combination of deep learning, uncommon poetic talents, and the manners of a courtier as Schlegel presented, she became his sincere friend, and henceforth accompanied her during several years on her travels through various parts of Europe. The reciprocal influence of these two distinc- ted talents was so great that each other was the reverse of his genius. They were published under the title ' Vor- lesungen über Dramatische Kunst und Literatur,' Heidelberg, 1809-1811, 3 vols. in 8vo.; and edition, 1817. A new col- lection of them was published in Berlin a few years before. In 1816 among which are his masterpieces, Arion, Pygmalion, Saint Lucas, and others. At that time Schlegel and his brother Frederic had already succeeded in founding, in opposition to the models commonly called classical, the modern romantic school of poetry and fine arts which had its origin, in a great measure, in the depressed state of Germany and the deep wishes of the people for a moral, religious, and political re- generation. Some enthusiastic patriots, and Augustus William having ventured to depreciate the French drama and to call Molière a mountebank, at a time when such liberties met with punishment or cruel penalties, the importance of this opinion was made popular to a degree which he would perhaps not have enjoyed at another time. 'Das Deutsche Museum,' a review which the brothers Schlegel founded in 1812, was the chief mekest besides other romantic periodicals with 'Das Romantische,' 'Das Deutsche,' 'Das Literatur,' 'Das Recht Deutschlands,' 'Das Deutsche Journal,' 'Das Deutsche Almanach,' 'Das Deutsche Monthly,' and 'Das Deutsche Monat.' Among the best are 'Das Deutsche Museum,' 'Das Deutsche Journal,' and 'Das Deutsche Almanach.'

In 1810, Augustus William von Schlegel was appointed professor of history in the university of Bonn, which had just been founded by the king of Prussia: it is not known why he was made professor of history, for he had never written on history. He had now ceased to be a poet, but still ambitious of the honours of the French language. He published several critical essays-of undoubted merit, however—in foreign languages. Such are, 'Le Couronnement de la Ste. Vierge, et les Miracles de la Vierge,' a translation of Tableau de Jean de Fieschi; with an notice on la Vie du Peintre, Paris, 1811; a fol.; an essay on the famous Venetian horses, which he declared to be of Greek workmanship, in Italian, in the 'Biblioteca Italiana.' 'Réflexions sur les Études des Langues Asia, adressées a Sir J. Macintosh suivies d'une Lettre à Mr. H. H. Wilson,' Bonn, 1832, 8vo. To such minor works, however, he devoted only part of his time, for even proviso to his appointment at Bonn, and at the suggestion of his brother Frederic, he had made up his mind to study Sanscrit. He so attracted a small number of students round him, and thus became one of the principal promoters of the study of the Ancient languages, and the printing-office at Bonn owes its foundation to Schlegel, who, it is said, purchased the types at his own expense. Although he did not attain the exact knowledge of that difficult language which his brother with so much exertion was still trying to reduce to exhaustion, Turin, however, had yet no contemptible Sanscrit scholar, and surpassed Bopp and others in his general views: and it may be that his principal merit consisted in encouraging students and aiding them in pursuing the study of Sanscrit, Zend, Persian, and other Indo-Persian languages. Schlegel in his turn was assisted by the superior learning of Professor Lasen. As early as 1820 he founded the 'Indische Bibliothek,' a review exclusively devoted to Indian languages and antiquities. Specimens of Schlegel's Sanscrit scholarship are, 'Ramāyana,' with a Latin translation and critical notes, Bonn, 1829; 'Bhāgavat-Gīta,' an episode of the celebrated Indian epic 'Maha- bharata.' It is in a great, and may be traced in his works: the result was, that he made her popular in Germany, and she brought him out in France, where his vanity afterwards met with so much gratification. At her mother's instance, he was published in 'Dante and His Contemporaries,' the Phoebus of Racine and the Hippolytos of Euripides, and this work was the foundation of his subsequent fame among the French. In 1806 Schlegel delivered at Vienna a course of lectures which was published in the 'Salzburgische Zeitung,' among which are his masterpieces, Arion, Pygmalion, Saint Lucas, and others. At that time Schlegel and his brother Frederic had already succeeded in founding, in opposition to the models commonly called classical, the modern romantic
Schoenberg is one of the most celebrated of the early German painters and engravers. He wrote, according to recent discoveries, born at Ulm of a family which produced many artists in the early part of the fifteenth century; his name occurs in Ulm documents from 1441 to 1461. The inscription which stood before his name in the gallery at Munich, though probably authentic, is apparently erroneous. He settled about 1461 in Colmar, and died there in 1485 or 86, Sandrart says 86, and various incidents prove the date by Nagler to establish this date. The time of this painter's death has until very lately been a matter of much dispute.

Martin appears to have been chiefly an engraver in his youth, and to have been called by the Italians Martino da Pordenone; and by a letter of Lambert Lombardus to Vasari dated April 27, 1566, and published by Gaye in his Cariclegio Inedito d'Arati, iii, 177, it is supposed that he studied under Roger Van Bruges, now from good evidence considered to be the painter of the portable altar of Charles V., which has been hitherto attributed to Memling. S. myricoides is found on turfy bogs in Great Britain. It has a round naked stem, from 5 to 10 spikes, celed into a terminal roundish head, overtopped by the lower bract; the glumes scarious at the keel. The stem is clothed at the base with a tuft of pubescent sheaths of which each is

and in have His this the the formed & 38, Mr. The of schools of dark-brown be of evidence of return of Rev. of New of Henry Brougham, now Lord Brougham, was chairman of the committee, and the evidence is printed in the 'Report from the Select Committee of the House of Commons in 1816.' Henry Brougham, once after committee, stated that he had been upward of six years in the superintendence of the cotton-mills there, and that there were 444 children in his schools at the time when he was examined (1816) from three to ten years of age, inclusive. As to the origin of these schools he says, 'I have been led in the establishment at Lanark, to receive children at the age of three years, principally for the purpose of preventing them from acquiring bad habits, which they would have done if they had been permitted to ramble in the streets among children who were ill instructed, and whose habits were bad: and also for the purpose of giving them good habits, and for settling the knowledge they acquire more firmly in their minds. They are continued in the school upwards of seven years.'

Mr. Owen gave the following account of the management of the schools:

'The children are received into a preparatory or training school at the age of three, in which they are perpetually superintended, to prevent them acquiring bad habits, to give them the best ideas of cleanliness and mutual kindness, and a sincere desire to contribute all in their power to benefit each other. These effects are chiefly accomplished by example and practice, precept being found of little use, and not comprehendible by them at this early age. The children are taught also whatever may be supposed useful that they may understand, and this instruction is combined with as much amusement as is found to be requisite for their health, and to render them active, and happy, fond of the school and of their instructors. The school in bad weather is held in apartments properly arranged for the purpose; but in fine weather the children are much out of doors, that they may have opportunities of sufficient exercise. In this training school the children remain two or three years, according to their bodily strength and mental capacity. When they have attained so much strength and instruction as to make them capable of mutual kindness and a sincere desire to contribute all in their power to benefit each other, they are admitted into it; and in this school they are taught to read, write, account, and, the girls, in addition, to sew; but the leading object in this stage of their instruction is to form their habits and dispositions. The children generally attend this superior day school till they are ten years old; and they are instruction and useful amusement for an hour or two every day during the whole of this latter period.'

In the year 1819 Henry Brougham, the Marquis of Lansdown, Joseph Wilson, John Smith (who had seen the schools at New Lanark five years previously), Joseph Wilson, and other gentlemen, established, by subscription among themselves, a school in Brewer's Green (now Vincent Square), Tothill Fields, Westminster, on the plan of Mr. Owen's school at New Lanark; and James Buchanan, an experienced teacher at the Manchester School, was engaged with Mr. Owen's approbation, to superintend the new school.

On the 24th of July, 1820, an infant school was opened in Quaker Street, Spitalfields, London. This school was established at the expense of Joseph Wilderspin, a dissenting minister, as a demonstration. Samuel Wilderspin and his wife were engaged to manage the school, and their salaries were fixed and paid by Mr. Wilson. Mr. Wilderspin had been previously a clerk in a London office, and he and his wife, having saved some money, published a small work 'On the Importance of educating the Infant Poor from the age of eighteen months to seven years, containing an account of the Spitalfields Infant School and the new System of Instruction there adopted.' By S. Wilderspin, master of the above school, 12mo., 2nd edition, with considerable additions, London, 1824. The first edition was probably published in 1822, but we have no evidence. Mr. Wilderspin was afterwards employed in delivering lectures on infant education, in assisting in the establishment of new schools, and in otherwise promoting the cause of infant education in all parts of Great Britain as well as in London. Mr. Buchanan was master of the infant school at twenty years, and then went to America.

A pension of 100l. a year was granted (August, 1846) to Mr. Wilderspin, who was before a committee of the House of Commons in 1816. Henry Brougham, now Lord Brougham, was chairman of the committee, and the evidence is printed in the 'Report from the Select Committee of the House of Commons in 1816.' Henry Brougham, once after committee, stated that he had been upward of six years in the superintendence of the cotton-mills there, and that there were 444 children in his schools at the time when he was examined (1816) from three to ten years of age, inclusive. As to the origin of these schools he says, 'I have been led in the establishment at Lanark, to receive children at the age of three years, principally for the purpose of preventing them from acquiring bad habits, which they would have done if they had been permitted to ramble in the streets among children who were ill instructed, and whose habits were bad: and also for the purpose of giving them good habits, and for settling the knowledge they acquire more firmly in their minds. They are continued in the school upwards of seven years.'

Mr. Owen gave the following account of the management of the schools:

'The children are received into a preparatory or training school at the age of three, in which they are perpetually superintended, to prevent them acquiring bad habits, to give them the best ideas of cleanliness and mutual kindness, and a sincere desire to contribute all in their power to benefit each other. These effects are chiefly accomplished by example and practice, precept being found of little use, and not comprehendible by them at this early age. The children are taught also whatever may be supposed useful that they may understand, and this instruction is combined with as much amusement as is found to be requisite for their health, and to render them active, and happy, fond of the school and of their instructors. The school in bad weather is held in apartments properly arranged for the purpose; but in fine weather the children are much out of doors, that they may have opportunities of sufficient exercise. In this training school the children remain two or three years, according to their bodily strength and mental capacity. When they have attained so much strength and instruction as to make them capable of mutual kindness and a sincere desire to contribute all in their power to benefit each other, they are admitted into it; and in this school they are taught to read, write, account, and, the girls, in addition, to sew; but the leading object in this stage of their instruction is to form their habits and dispositions. The children generally attend this superior day school till they are ten years old; and they are instruction and useful amusement for an hour or two every day during the whole of this latter period.'

In the year 1819 Henry Brougham, the Marquis of Lansdown, Joseph Wilson, John Smith (who had seen the schools at New Lanark five years previously), Joseph Wilson, and other gentlemen, established, by subscription among themselves, a school in Brewer's Green (now Vincent Square), Tothill Fields, Westminster, on the plan of Mr. Owen's school at New Lanark; and James Buchanan, an experienced teacher at the Manchester School, was engaged with Mr. Owen's approbation, to superintend the new school.

On the 24th of July, 1820, an infant school was opened in Quaker Street, Spitalfields, London. This school was established at the expense of Joseph Wilderspin, a dissenting minister, as a demonstration. Samuel Wilderspin and his wife were engaged to manage the school, and their salaries were fixed and paid by Mr. Wilson. Mr. Wilderspin had been previously a clerk in a London office, and he and his wife, having saved some money, published a small work 'On the Importance of educating the Infant Poor from the age of eighteen months to seven years, containing an account of the Spitalfields Infant School and the new System of Instruction there adopted.' By S. Wilderspin, master of the above school, 12mo., 2nd edition, with considerable additions, London, 1824. The first edition was probably published in 1822, but we have no evidence. Mr. Wilderspin was afterwards employed in delivering lectures on infant education, in assisting in the establishment of new schools, and in otherwise promoting the cause of infant education in all parts of Great Britain as well as in London. Mr. Buchanan was master of the infant school at twenty years, and then went to America.

A pension of 100l. a year was granted (August, 1846) to Mr. Wilderspin, who was before a committee of the House of Commons in 1816. Henry Brougham, now Lord Brougham, was chairman of the committee, and the evidence is printed in the 'Report from the Select Committee of the House of Commons in 1816.' Henry Brougham, once after committee, stated that he had been upward of six years in the superintendence of the cotton-mills there, and that there were 444 children in his schools at the time when he was examined (1816) from three to ten years of age, inclusive. As to the origin of these schools he says, 'I have been led in the establishment at Lanark, to receive children at the age of three years, principally for the purpose of preventing them from acquiring bad habits, which they would have done if they had been permitted to ramble in the streets among children who were ill instructed, and whose habits were bad: and also for the purpose of giving them good habits, and for settling the knowledge they acquire more firmly in their minds. They are continued in the school upwards of seven years.'

Mr. Owen gave the following account of the management of the schools:

'The children are received into a preparatory or training school at the age of three, in which they are perpetually superintended, to prevent them acquiring bad habits, to give them the best ideas of cleanliness and mutual kindness, and a sincere desire to contribute all in their power to benefit each other. These effects are chiefly accomplished by example and practice, precept being found of little use, and not comprehendible by them at this early age. The children are taught also whatever may be supposed useful that they may understand, and this instruction is combined with as much amusement as is found to be requisite for their health, and to render them active, and happy, fond of the school and of their instructors. The school in bad weather is held in apartments properly arranged for the purpose; but in fine weather the children are much out of doors, that they may have opportunities of sufficient exercise. In this training school the children remain two or three years, according to their bodily strength and mental capacity. When they have attained so much strength and instruction as to make them capable of mutual kindness and a sincere desire to contribute all in their power to benefit each other, they are admitted into it; and in this school they are taught to read, write, account, and, the girls, in addition, to sew; but the leading object in this stage of their instruction is to form their habits and dispositions. The children generally attend this superior day school till they are ten years old; and they are instruction and useful amusement for an hour or two every day during the whole of this latter period.'

In the year 1819 Henry Brougham, the Marquis of Lansdown, Joseph Wilson, John Smith (who had seen the schools at New Lanark five years previously), Joseph Wilson,
the genus Sciara, of which a single species, the maggot, Sciara aperta, occasionally occurs from the seas of South Europe into our own. Haemulon, Pristona, Diagramma, and Amphipiron are among the many genera belonging to the second section.

DONEMOCINO, born at Palermo in 1765, studied in his native town under Rosario Gregorico and other good masters, and became a proficient in classical erudition. Afterwards he applied himself to the study of the mathematical and physical sciences, and to the theorems of the science of life, which he chiefly devoted. In 1796 he was appointed Professor of Physics in the University of Palermo. He was repeatedly sent by the government to various parts of Sicily to explore the geological, mineralographic, and agricultural resources of the islands, and to examine the results of his observations. He gave an account of the eruption of Etna of 1811, in two letters: 1. Lettere scritte da Catania a Monsignore Gramsci in Messina. 2. He wrote on the curiosities of the strata of Messina; 3. Memoria dei Fili Refidi, e i Vorticari appartenenti dello Stretto di Messina; in which he gave a better explanation of them than either Spallanzani or M. Recucci, has done. In 1788 he published an interesting paper, 'Topografia di Palermo e dei suoi Contorni,' in which he describes the geographical aspect of the tract, its geological and mineral formation, its vegetable and animal productions, and its meteorology, with the hortus focus, &c. In the following year he was sent to explore the mountainous group called Monti Madonie, the ancient Nebrodes, which rises in the centre of the island, especially with regard to the fragments of the ancient apparatus, &c. Di Benvenuto, 'Rappo della Visita alle Madonie, Iscriv. per Ordine del Governo,' Palermo, 1819. In 1823 he went on a like mission to the district of Ogliastro, near Termini, where an earthquake had recently occurred, and on the spot he observed the springs of the mineral waters from which the town of Termini takes its name. He wrote two reports on the subject, which were inserted in the Sicilian 'Giornale di Scienze, Lettere, ed Arti.' In 1829, on the occasion of some fossil remains found in the neighbourhood of Palermo, Scina wrote a 'Rapporto sull' Ossa Fossili di Mardolce e degli altri Contorni di Palermo,' which attracted much attention. When a volcanic explosion occurred in Sicily in 1880, Scina was sent to examine the new phenomenon, and he wrote a 'Breve Rappaggicli del nocciolo Vulcano.' Scina was not neglected by the Sicilian government. Both King Ferdinand and his successor King Ferdinand bestowed their favour upon him. In 1816 he was appointed historiographer of Sicily.

In 1822 he was made chancellor of the University of Palermo, and a member of the commission of public instruction and education for the whole island. In 1823 he was made curator of the public library of Palermo, and also rector of the 'Educatore dello Nobili Donzelle,' or 'House of Education for young Ladies of Bank.' In 1829 King Francis presented him with a valuable book, fixed at the library of the University of Sicily. 3. 'Elogeo di Francesco Maurolico,' a distinguished mathematician of Messina in the sixteenth century. 4. 'Memorie sulla Vita e Filosofia di Empedocle, Girgentino,' in 2 vols. Svo., Palermo, 1819, a work more censured but not less accurate and interesting than that of F. W. Sturz, Leipzig, 1805, on the same subject. Scina's book is divided into four parts: the first treats of the time in which Empedocles lived; the second is a biography of the Antiquite philosopher; the third treats of his philosophy; and the fourth is a collection of the fragments of his works translated into Italian. 5. Discorso inteso ad Archimede. 6. 'Saggio di Storia Naturale e Tertia di Palermo,' 1823, with a biography of that ancient and little-known Sicilian poet. 7. 'Prospecto della Storia Letteraria di Sicilia.' This is one of Scina's latest works, to which it bears a very fragmentary title. 8. 'Lettera al Padre Pianzi intorno a Girolamo Settimo, Matematico Palermitano.' 9. 'Esperienze e Soveroie sull'Elettromagnetismo.' Scina died of the Asiatic choler, which afflicted Palermo in July, 1867. He was one of the most learned men to remain Palermitani has produced.

(Tipalelo, Biografia degli Italiani Uomini; Mortillino, Sulla Pianta di Sciara, detta Sciara aperta. Abate Domenico Scina. Palermo, 1837.)

SCILOPTIC BALL is a globe of wood about five inches diameter, with a cylindrical perforation 2 inches diameter passing centrally through it, and having at one extremity of the perforation a glow iron. Connected, and fixed by a number of screws, fixed in a socket, which is made in a board about 8 or 10 inches square, in such a manner that while it cannot fall out, it is capable of being turned on its centre, to a small extent, in any direction.

The board being screwed to a window-shutter, or to the vertical face of a building in which an aperture has been made for the reception of the globe; the rays of light from external objects, after being transmitted through the globe, are reflected by the images of those objects on the opposite wall of the apartment, or on a white screen placed in a vertical position to receive the light; the apartment being darkened in order that the images may be distinctly visible. The images on a vertical screen being inverted, two arms generally project from the board, within the room, and carry a plane mirror which turns on an axis so as to allow the rays of light, after passing through the lens, to fall on a screen placed in a horizontal position; by this means the spectators are enabled to see the images in correct positions. [Camera Lucida and Camera Obscura, P. C.]

When the construction of the building is such as to allow the ball and lens to be fixed at an aperture in the roof, a plano mirror being placed above it at an angle of 45 degrees to the horizontal, so as to reflect the rays from external objects down on the lens, the images forming on a screen within the darkened apartment are more distinctly formed and more conveniently seen. An apparatus of this nature was formerly applied to the roof of a building connected with the astronomical observatory at Greenwich, Edinburgh, and Glasgow, for the amusement of visitors.

SCIRPUS, a genus of plants belonging to the natural order Cyperaceae and suborder Cyperoideae, is divided into nearly equal glumes; the lower ones are perhaps the largest, and one or two of them empty. The bristles are either absent, or about six in number. The nut is plano convex or trigonous, inserted in the filiform not dilated base of the style. S. maritimus has stalked or scaly spikes in a dense terminal cluster, several foliaceous bracts, bifid glumes, with an intermediate point; acute segments and a trigonous smooth or crumpled style. S. Crinus and the tribe Scirpeet has a nut-shaped spore, which is in salt marshes in Great Britain, and is much relished by cattle. Withering says that the roots of this species are excellent, and have been ground down and used instead of flour in times of scarcity.

S. lascutia, Bullrushi, has a round stem from four to six feet high, naked, with one or two long sheaths at the base, the spikes in a terminal twice compound panicle; the glumes emarginate, mucronate, glabrous, and fringed. The nut obtusely trigonous and obovate; stigma three. The panicle is not lateral, although the bract closely resembles a continuation of the stem. It is found in rivers and ponds in England. The root is saturated and is used in medicine. The leaves are employed for making matting, chair bottoms, and many other domestic purposes.

S. triqueter has a stem scutately triquetrous throughout, flat or concave between the nodes, and the spines ascending from the base, the upper one terminating in a very broad triquetrous leaf. The spikes are in a small cymose panicle, the glumes emarginate, mucronate, glabrous, and fringed, the lobes rounded obtuse, and the nut rounded oblate, plano-convex, and smooth. This species is found on the muddy banks of the Thames, near London, and the Arun, near Amberley, Sussex.

S. Holoschoenus is the &lt;br>&lt;br>
S. tuberosus is the Pl-tai, or water-chestnut, of the Chinese, and is cultivated by them for food in large tanks, which are regularly manured and the water at intervals drawn off. The tubers are eaten boiled or roasted, and are used as food and medicine. There are fourteen British species of Scirpus, none of which however are worth description on account of any qualities they possess. (Babington, Mem. Br. Bot.; Lindley, Veg. King; Burnett, Outlines of Bot.)

SCLERANTHUS (from scler-ath, hard, and &lt;br>&lt;br>
Scleranthus (from scler-ath, hard, and &lt;br>&lt;br>
Scleranthus (from scler-ath, hard, and &lt;br>&lt;br>
are small, greenish white, and sessile in the axils of the fork of the branches.

t. crassifolia, Annual Knawel, has subdecandrous flowers, seg-
mented by the stamens, six of the fruit, patent style, with a very
membranous margin as long as their tube. The styles are
longer than the stamens, the stem green and repeatedly
dishomotous. The flower green, often solitary. It is found in
the eastern part of the British Isles and Germany.

The rachis of the fruit is thin, and the seeds are round and in
the Polish cochinial (Coccus Polonicus) is frequently found
on the roots and leaves of this plant in the summer months.

The seeds of these plants only require to be sown in the open
border. Of one of the species are worth cultivating except in
b辜nical collections.

SCLERODERM, a genus of grasses belonging to the tribe Festucaleae. It
has unequal acute membranous glumes. The outer panicles with
4 main but distinct and parallel nerves, membranous, cylindrical
below, smooth, often keeled at the tip or with a very minute
membrane. The styles are terminal.

S. maritima has a branched panicle, the lowest branches in
pairs or simple, the branches alternately erect, the spikele-
ks linear, that are 2 to 6 flowered, the outer panicles oblong,
the midrib not reaching to the apex, the root fibrous, without rooting
scales. It is found on sandy shores in England.

t. procerula is known by its ovate lanceolate compact panicle,
linear lanceolate spikelets of about 4 flowers, the rachis terete,
angular, the outer panicles oblong, with an apicus
formed by the extremity of the dorsal nerves; the root is
fibrous; the flower large. It is found in salt marshes in Britain.

There are six British species of this genus.

SCLERODERM, the second family of Plectognathous
fishes (such as have incomplete and soldered jaws). The
Scleroderma are distinguished by their conical or pyramidal
snouts, with or without lateral teeth in the upper
jaw. The skin is rough, or covered with large hard scales.
The first division of Plectognath is named Gymnoderas.
The fishes included in it have no true teeth, but a substitute in
the form of scales, which were not rooted in the bone of the lower
jaw. It includes the Pterodon, the Diodon, the Orthoge-
ricus, or sun-fish, and other genera.

The Scleroderma are mostly tropical fishes, and are
remarkable for their hard dragon-like plates, the teeth,
the tail, the mouth, and gill-openings passing through
holes in its coat of mail.

SCLE/RODUS, a genus of fossils from the upper
Siberian strata of Lovlow, &c. (Asgasia.)

SCLEPENDRUM, a genus of forms belonging to the
tribe Apleneae. The soroi elonget, straight, and two-
gether. The lunula of each pair opening towards each other.
S. nuphar, Hart's tongue, is a particularly handsome and
ornamental plant, very different from every other British
species. It is universally and abundantly distributed through-
out the British Isles. It is very commonly found on old walls
and ruins. It was first found in Europe, sparingly towards
the south and in the United States. It is described as growing in Africa, Asia, or South America.

The roots are black, stout, and very long and strong, the
rhizomes blackish, scaly, almost spherical, the young
fronds make their appearance very different from every other
British species. It is universally and abundantly distributed throughout
the British isles. It is very commonly found on old walls
and ruins. It was first found in Europe, sparingly towards
the south and in the United States. It is described as growing in Africa, Asia, or South America.

church. At the revolution the presbyterian form was re-established. The followers of this system, who through the opposition of the covenanters distinguished themselves, have been to be made an exclusive establishment, now thought that the hour was come for the extermination of their opponents; but they were told by King William that that was a word not in his power. Nevertheless, the first act of the Scottish parliament was the re-establishment of an act of the British parliament in 1710. This act created many disputes in the church; it occasioned the secession of 1736, and the act was passed [Free Church, P. C. S]. It was the cause of the great secession in 1843 [Free Church, P. C. S]. In the same year with that secession an act was passed for modifying the right of patronage, called Lord Aberdeen's Act, (67. 32) in which a measure was taken to have been passed for the purpose of satisfying the scruples of some clergymen who would not remain in the church as it was, but would continue with a less comprehensive measure than the Veto Act. The difference between these two systems was, in the first place, that the Veto Act bore to be passed by authority of the church, its supporters denying that they required the interposition of any lay legislature. By that measure, the simple object of a certain number of the male communicants without any reason given, was a cause of disqualification to a presbyter. By Lord Aberdeen's Act, any members of the congregation may object to the presbyter, stating his case in the courts, and they think them good, whether in their general tenor, or with respect to the particular circumstances of the charge, may give effect to the reason by rejecting the presbyter.

SCOTT. [Eldon, P. C. S.]

SCOTT. [Stowell, Lord, P. C. S.]

SCREW-PILES. [Sea-Lights, P. C. S.]

SCREW-PROPULSERS. [Stewart, Vasco-Navar, P. C. S.]

SCROPHULARIA (so named from its supposed use in cases of scrofula), a genus of plants belonging to the natural order Scrophulariaceae. It has a 5-parted nearly equal calyx, a globose corolla, with a short 5-lobed limb, the segments of which are rounded at the upper end, united into an upper lip. The style is simple thickened at the apex, the stigma emarginate. There are four fertile disomes (stamens) with the rudiments of a fifth appearing. The species are herbs or shrubs with an unpleasant smell.

S. perennis, Figwort, has cordate shining glabrous leaves, alternate peduncles from 2 to 5 flowered, the lobes of the calyx not membranous, globose and acute. The stem is acute-angled at the base, but obtuse apexed at the apex, and of a dark purple. The leaves are full of pellucid dots. The corollas small, purple, and veiny, the lobes all denticulated. This species grows in moist places.

S. nodosa has a round smooth herbaceous, which when bruised smells like elder. The root is whitish, tubular, and beset with pellucid knots. The leaves are stalked ovate oblong, acute, sharply and unequally serrated, hardly hairy on the back. The corollas are divided into two small lateral ribs. The flowers are a little drooping, the corollas of a dull green, with a livid purple lip, the calyx is smooth, the capsule ovoid ellipsoid, ridged and hairy. They have a bitter taste and a disagreeable smell. A decoction is used by farmers to cure the sear in swine. Wasp greatly resort to the flowers. Goats eat the plant, but other animals refuse it. It is native mostly throughout Europe.

S. aquatica has an entirely fibrous root. It is a smooth plant of a deep shining green colour, the stem is quadrangular downwards, the leaves copiously and finely serrated, heart-shaped at the base. The flowers are in clusters, their tube is green, the corolla of a deep red. The capsule globular. This plant is called Water Betony, Bishop's leaves, and Broadroot. It is called by the French Berbe du siege, because during the siege of Rochelle by Cardinal Richelieu the garrison supported themselves in extremity by eating the roots.

It was released from the list of the plants reported by the French Academy, that the plant is identical with the Equisetum of the Brazilians, celebrated as a corrective of the unpleasant flavour of senna. The Edinburgh college, in their common inflation of the plant, have placed it under the care of the Academy, and continued it, we infer that it was not found to exercise the desired effect. The disagreeable smell of the plant causes cattle to reject it as food. Bees collect much honey from the flowers.

S. stricta, or Figwort, has these six generally recognised British plants. They are very of easy culture and propagation, but prefer a moist situation. They are all readily propagated by seeds. The shrubby species require protection during the winter in some districts.

(Don, Gardener's Dictionary, Babington, Manual of British Botany; Burnett, Outlines of Botany.)

SCUTELLARIA (from the Latin 'scutella', 'a little saucepan', in reference to the form of the calyx), a genus of plants belonging to the natural order Labiatae. It has a campanulate bilabiate calyx, the lips entire, the upper one with a concave scale on its back. The tube of the corolla, much exerted, 2-lipped, with the upper lip corolla entire, its segments simple; the anthers of the two longer and inferior stamens 1-celled, of the shorter and superior one 2-celled. The species are annual or perennial herbs, rarely shrubs.

S. galericulata. Suckling has branched divergent stems, leaves on short petioles, oblong, lanceolate, cordate below, crenate, serrate; flowers axillary, opposite, and on short pedicels. The corolla is large and blue. The whole genus is remarkable for being provided with a curved, elongated support to its nut. This species was once considered efficacious in certain fevers. It is plentiful in Europe, Asia, and North America, in humid places, and in Britain.

S. minor, smaller Scullcap, is a humble glabrous plant, with its leaves on short petioles, the lower ones broadly ovate, the middle ones ovate-lanceolate with the base cordinate, the upper one lanceolate, rounded at the base; the flowers axillary, the stamens opposite, secured at their roots, their segments abruptly narrowed and hardly dilated. It is native of Europe and Siberia, in damp places, and of Great Britain.

S. lateriflora has erect fleshy stems, pedate ovate lanceolate acuminate, rosetted at the base; the upper floral leaves hardly exceeding the calyces, the racemes axillary and terminal, the flowers opposite and secund. It is native of North America, on the margins of ponds, and was once extolled as a remitter for bleeding, but on no good grounds. Most of the species of Scutellaria are very pretty ornamental plants, and will grow in any common soil.

(Doon, Gardener's Dictionary, Babington, Manual of British Botany; Burnett, Outlines of Botany.)

SCULLYODUS, a genus of fossil fishes. (Agassiz.) From the chalk.

SCYPHIA, a fossil genus of Spongiate. Chiefly in the chalk. (Goldfuss.)

SEA-LIGHTS. Since the publication of the article Lighthouse-Houses, P. C. S., p. 478, some changes have been effected in the management of the coast-lights and beacons of the United Kingdom, and many important points with respect to increasing the efficiency of sea-lights have been introduced. Our brief notice of these will be briefly founded upon the Report of the Select Committee of the House of Commons on Light-Houses, in the Report of 1845, 'Recent Improvements in Light-Houses,' published in the 'Penny Magazine' for 1842, pp. 286 and 294.

The Select Committee of 1845, having directed their attention chiefly to the better management of light-houses and lighthouse establishments of the British Islands subsequently to the date of the Report of the Committee of 1834 (extracts from which are given under Lighthouse-Houses), report that by an act of 1856 (6 & 7 Will. 4, c. 78), all light-houses and sea-marks on the coasts of England were vested in the corporation of the Trinity House (Triinity House of Deptford, P. C. S., p. 245), which was empowered by the act to purchase the private light-houses of Harwich, Dunse, Winterton, Husanton, and Orford, which were held by individuals under leases from the crown; the Smalls and Longships, which were held on leases under the Trinity House itself; and the Skerries, Sperms, and Tynemouth lights, which were held by private parties in perpetuity under acts of parliament.

The purchase of these ten lights was effected (the amount of the purchase money was £80,000) for the purposes for the interests of individuals, of 1,182,540l.; and the rights of the crown on the five first were surrendere`d on condition that the Possessions and Land Revenues of the Crown should not exceed £1,000,000, upon the issue of a consolidated fund on their security. Thus, at a very large cost, the recommendation of the Select Committee of 1834 'to have all public lights placed under one board, and free from private claims' has, so far as this act of parliament has gone, been carried into effect, and, as the Committee of 1845 observe in their Report, parliament will thereby be enabled to legislate freely respecting them, in such manner as shall be considered best for the public interest.

Sealights are commonly divided into two principal classes,
In addition to the above there were, in 1844, 7 local lights belonging to the Isle of Man, which, having been included in the returns for 1838, we have omitted in those for 1844. These raise the number of local lights for the United Kingdom to 150, and the gross number of lights to 509.

Of the 04 fixed general lights in England and Scotland 76 were, in 1844, coterie lights, with an aggregate number of 1098 burners, which gives an average of nearly 144 burners to each light, and 18 were dioptric, of power equal to an aggregate of 288 burners, which gives an average power of 14 burners to each light. The aggregate illuminating power of the fixed general lights in England and Scotland was, therefore, equal to 1366 burners, while that of the 25 English floating general lights (exclusive of that at Plymouth breakwater) was 288 burners, giving an average power of 11.4 burners to each light. In Ireland the 27 fixed general lights had an aggregate power of 583 burners, which gives an average of rather more than 21.4 per light.

From the evidence laid before the committee of 1845 it would appear that the public general lights of the United Kingdom are in an efficient state, and, according to a witness who had ample opportunities of comparison, on the whole superior to those of the United States of America; but while no complaints were made of their want of brilliancy or general efficiency, many were laid before the committee, both by pet owners and on their own admission, of the defective light, the inadequacy of lashing them, or the irregularity of their rates. How greatly the gross amount levied upon commerce in the shape of light dues has increased since the date of the Report of 1839 is evident from the following comparative statement of dues levied in each division of the United Kingdom in 1832 and 1843. The return for England and Scotland appears to apply solely to general coast lights, no complete account being given of the dues levied on breakwaters; but that for Ireland embraces such, they being, as before stated, in the hands of the Ballast Board. Of the dues levied in England in 1832, only 88,041l. belonged to the Trinity House, and 70,676l. to private individuals; in 1843 the whole fell into the hands of the Trinity House.

From the statements laid before the committee of 1845, it appears that these charges, which, in consequence of the general reduction of freight and the competition to which ship-owners are exposed, and to which we are interestingly alluded in the Report of 1839, are not only more oppressive to trade, but for the mere maintenance of the lights, but are also levied on a much smaller and more lenient plan, as appears upon particular branches of the shipping interest. Steerage packet companies especially complain of the amount of the dues as compared with the advantages derived. The Peninsular and Palace Steam Packet Company, for instance, being 20 years engaged under the charter, and their vessels employed on the Peninsular line, of an average tonnage of 368 tons, and making fifty-two voyages in the year 1844, paid 12l. 7s. 4d. per voyage for light dues, or 545l. 1s. 4d. in the course of the year, and that two others, plying between Southampton and Alexandria, averaging 888 tons each, and making twelve voyages in the year, paid 220l. 14s. per voyage, or 2696l. 8s. per annum. One case that appears of peculiar hardship is that of a small steamer engaged between Grunton, in the Firth of Forth, and Dundee, completing her voyages entirely by daylight, and therefore deriving no benefit whatever from the lights, but which, nevertheless, paid dues to the following amount in one year, during which it was at work for forty-nine weeks, and three weeks refitting:

*49 belonging to the Trinity House, 1 under their management, and 14 in private hands; viz. 3 on lease from the Trinity House, 7 on lease from the owner of the respective lighthouses; 12 belonging to the Trinity House, and 1 under their management. Of the 25 public general lighthouse stations, but at four of these, viz. the Isle of May, Pentland Firth, Fladda, and the Eddystone, which are laid down in the table, the number of lights was as given in the table. These new light houses, not included in the return, were stated to be in preparation. In addition to the 29 permanent local or harbour lights reported, there were some used in the fishing season only.*

In 1844, 20 local or harbour lights were in commission. In 1832 there were only 11, and in 1835 only 15, showing an increase in little more than ten years (for the returns dated 1834 refer, at least in some cases, to 1833, while those given under 1844 appear to actually for that year), of 88 stations, classified as follows:

Total for forty-nine weeks | 7092. 4s.
1843 and 1844 thirteen voyages, with an average load of 400 tons, earning a gain of 2007l. 18s. 1d., out of which 69s. 10s. 7d., or more than 23 per cent., had to be paid for light-dues; and Mr. Ogilby, a London shipbroker of forty years' standing, stated, in evidence, that the traders to the principal ports of Ireland have paid on the average 5s. 14d. per ton on the average of the year; that the Mediterranean and the South of Europe, making a less number of voyages, pay 3s. 6d. per ton; and that ships to India and China, making one voyage in the year, 1s. 14d. per ton; and that the coasting trade in the great western ocean, would, he thought, consequently benefit the most by the abolition of the light-dues.

The following table, compiled from the returns given in the Committee's Report, shows what proportion of the light-dues of each division of the United Kingdom is derived from each class of ships:—

The light-dues are, it should be observed, charged upon the whole tonnage of a vessel, however small may be the carrying capacity, or, as it is termed, the 'tonnage'; if one ton, or one box, or one passenger paying freight be on board from port to port, light-dues for the whole ship's tonnage is invariably charged; and consequently the ships often are deprived of considerable quantities of cargo, and the quantity of cargo; a course of proceeding which, in the commerce of Ireland, operates very injuriously on the merchants, and on the consumers in the smaller ports to which the vessels go for.

Of the recommendations of the Committee of 1845 for removing the evils complained of we need say very little, especially as nothing has, down to the close of the session of 1846, been done to give them legislative effect. Their principal features are the proposed transfer of the management of all public lights, buoys, and beacons, on the coasts of England, Ireland, and Scotland, to one central board, which is suggested should be the Corporation of the Trinity House, with some modifications in its constitution; the defraying by government of the heavy debt incurred by the Trinity House in buying up private lights; and the future maintenance of public lights, buoys, and beacons either out of the public revenues, or by a small tonnage-rate on all the registered tonnage of the United Kingdom, and all colonial and foreign vessels entering its ports: such rate being made out of the surplus revenue of the Corporation, which is that above the quantities previously paid for, like the present light-dues, a large surplus revenue for pensions and charitable purposes. They suggest that it may be considered whether the ships of the Navy, and those in the Customs, Revenue, and Excise, Service should continue to be, as they now are, exempted from the payment of these light-dues; and they conceive that a more economical mode of collection, by the agency of the officers of Customs, might be substituted for the present.

One interesting detail of the investigations of the late parliamentary Committee is that relating to the cost of various modes of illumination. Their Report states that for many years past the French have used colza or rape-seed oil, which costs about 3s. 6d. per gallon, while the best sperm oil, which is usually burnt in English light-houses, costs 6s. to 8s. per gallon. It is admitted that a greater quantity of colza than of sperm oil is necessary to produce the same effect; yet some of the witnesses examined expressed an opinion that one-half of the expense of the oil consumed might be saved by its use, and how seriously any such saving would affect the general cost of maintaining light-houses may be perceived from the statement that, out of 701, the total expense of the Flamborough light in 1843, 303l., was expended upon oil, and that in the Dungeness light-house the same item amounts to 225l. In a total expenditure of 592l. Mr. Alexander Gordon, however, in his evidence, objects to rape-seed oil because, in common with all other vegetable oils, it wastes by burning to overflow, and occasions increased labour in trimming the lantern, and, by theire being intermixed with a secret vegetable oil, makes the cost, and places next to it some of the South Sea whale oils, and then cocoa-nut and palm oils. In the United States, where the cost of maintaining light-houses is far less than in this country, experiments have been made on the comparative economy of various substances, from which it appears that burning for the whole night, and giving the same degree of light, 3-05 burners using hard-oil cost $2.49 cents each—

The following statement shows the average total cost per burner and per light-house of the public general lights of each division of the United Kingdom, and of the harbour-lights of Ireland, in 1844 and 1845. It is important to notice on the returns of 1832, the average cost for the United Kingdom being 456l. per annum in 1843-44, and 508l. in 1842:

We may conclude our statistical returns for England by noticing the number of buoys and beacons maintained by the Trinity House, and, for the sake of comparison, some figures relating to the sea-lights of France and America.

The beacon lights of the Trinity House, England, and Scotland, numbered 33, and in 1844, 46, showing an increase of 15. In 1833 the number of buoys under the same management was 227, and in 1844, 295, being an increase of 72. The beacons and other light-duties levied by the Trinity House, England and Scotland, and buos amounted to 14,207l. or 1042l. No corresponding duties are charged in Scotland and Ireland by the Northern Lights Commissioners and the Ballast Board, and the Light-houses Committee of 1845 recommended the abolition of such in England.

In France the light-houses and harbour-lights are all under a public board, and their expenses are paid out of the treasury, and met by levying a port-charge of 14d. per ton upon shipping instead of light-dues. There were, in 1834, 28 light-houses and 61 harbour-lights, making a total of 74; of which 29 were provided with lenticular apparatus, the nature of which is explained under Light-houses, P. C. S. No. 2671. The establishment of new lights has there proceeded more rapidly than with ourselves, the number having more than doubled in about ten years. In April, 1845, it was reported as 52 general coast light-houses and 101 harbour-lights, making a total of 153, of which 96 have lenticular apparatus. Some of these lights being grouped in twos and threes, the total number of light-house stations or separate establishments is only 105.

In the United States of America, where the general duties are supported by the general government, there were, on the 1st of July, 1842, 242 fixed and 50 floating lights, having an aggregate power of 2671 burners.

In advertising the introduction of one of the most important mechanical improvements recently introduced in the construction of light-houses, we may first notice the construction of such buildings wholly of iron or other metal. Though first carried into effect by Mr. Alexander Gordon, this improvement would appear from the first of the papers already referred to in the 'Fenny Magazine,' to have been previously suggested by the ingenious Captain (afterwards Sir) Samuel Brown, who is best known for his share in the introduction of suspension-bridges and piers, and who proposed to erect a light-house of either iron or bronze upon the Wolf Rock, near the Land's End. His plan was to construct a tower 50 feet high, 16 feet in diameter at the bottom, and 4 at the thinnest part, composed of several truncated conical pieces of cast metal, fitting one another like the joints of a telescope. Within the body of this metallic column were to be sleeping-lobits for the attendants, and storerooms for provisions, fuel, water, and oil; and at the top was to be the keeper's house, surrounded by an open hanging-galley, and surmounted by the lantern. Captain Brown conceived that such a structure would possess the advantages of being much less costly than a stone light-house; of requiring much less time for its erection; of presenting a much narrower surface for the sea to act against; and of greater security and stability, seeing that it was no less affected by the wind meeting the light than the lantern, while a stone structure would have many thousands, and that, the whole circumference of each stage or story being cast in one piece, it would be capable of resisting enormous pressure.

* Captain Brown's simple and ingenious design was not carried
into effect, but a cast-iron lighthouse on a somewhat different plan was erected in 1842, by Mr. Alexander Gordon, upon an unhealthily lagoon in Jamaica, where, owing to local difficulty, it was required that a tower should be placed at the coast, which had been constructed for less than 20,000£, or in a less period than six years, with the almost invariable loss of many lives. For this locality Mr. Gordon designed an iron tower forming one of the height of the highest point on the coast of Ireland. The erection was determined upon by the commissioners in Jamaica on the 5th of March, 1841; eight months after that date it was ready for shipment; and it was erected near the mouth of the Thames, in October, 1841, when lighted until November. The cost of the tower and lantern, including the fitting up in London, to pieces, packing, and shipping for its destination, was 5,500£, and the putting up was done at a cost of 2,200£. The total outlay in the case above stated cost about 600£. additional. The diameter of the tower is 18 feet 6 inches at the base, and diminishes regularly to 11 feet at the top; and instead of being formed, as in Captain Brown's plan, of a few large castings, each embracing the whole circumference, it is formed of nine tiers of cast-iron plates, each 10 feet high, from 4 feet to 5 feet wide, and nearly an inch thick, the circumference being composed of eleven such plates at the base of the tower, and nine at the top. These are cast with flanges all round their inner edges, and, when put together, these flanges form the joints, which are fastened together with nut-and-screw bolts, and caulked with lead. The upper part of the column consists of ten radiating plates, which form the floor of the light-room, these being secured to the tower upon twenty pierced brackets, and finished above by an iron rafter. The lantern is a cone-shaped iron box, with a glass dome, containing a revolving light, consisting of fifteen Argand lamps and reflectors, five in each side of an equilateral triangle; so arranged as to produce a continuous light, but with periodical flashes. The lower part of the rock, upon which is laid a grooved course of granite to receive the flange of the lower plates, from which lighting conductors extend into the sea. The base is also encased with granite, to protect the iron from the action of sea-water; as might filter through the stratum of sand which covers the coral rock; and the protection is increased by coating the exterior of the iron with tar. The interior of the tower, to about one-third of its height, filled up with masonry and concrete so as to form a solid core, which imparts great stability to the structure; and above this are the necessary rooms. Of the precise nature of the arrangements actually adopted for securing comfort in this singular habitation we are not informed, but it is stated in the 'Penny Magazine,' on the authority of a paper in the 'Civil Engineer's Journal,' published while the structure was yet in theoria, 'to preserve the air, and to regulate the temperature, the circumstances and climate will permit, the iron shaft or tower is to be lined with a non-conducting material, such as slate or wood, leaving an interstice through which a constant ventilation is secured, so as to carry off the excessive heat.' In his evidence before the parliamentary committee of 1845 Mr. Gordon stated that a taller and better lighthouse of similar construction was in progress for Bermuda, which would weigh about 190 tons, and would contain in its base about 450 tons of masonry and concrete. Among the numerous advantages of this kind of lighthouse may be mentioned their superior safety in thunder-storms, the whole structure constituting a great unbroken conductor for the lightning; and the safety arising from the whole being virtually in a single piece, and therefore far better able than a tower of masonry to resist the shocks of earthquakes, to which, as well as to intermittent thunder-storms, lighthouses are continually exposed. The iron-work is so constructed as to be readily put together from inside, without any external scaffolding; and these, in common with other points adverting to the economy of being easily removable, in case the shifting of sands or any other circumstance should render a change of position desirable; a contingency which, as will be seen by reference to the Argand lighthouse at E.C., p. 249, has occurred, and which is very likely to recur as the substitution of fixed for floating lights in the vicinity of shifting sands, and the general extension of harbour lights, proceeds.

The first screw-pile lighthouse was proposed in 1836 to a Select Committee of the House of Commons on Shipwrecks, by Mr. Bush, as suitable for erection on the Goodwin Sands, where the extreme difficulties of the locality have hitherto deterred the Trinity House from establishing any other than a floating light or lighthouse. Mr. Bush's plan, as then proposed, was to construct, on land, a wooden truncated cone 100 feet high, 60 feet in diameter at the base, and 12 feet in diameter at the cone which should be in contact with it at the base, but, diminishing less rapidly as it rose, should gradually recede from it towards the upper part. The intervening space between the base and the cone would be filled with earth and materials after the structure was floated to the required position, so as to sink it in the sea until it found a firm bottom. The sand in which the inner cone was then to be drawn out, remaining in place, and leaving the outer cone, though not subject to the same fate, would be supplied with a solid mass of masonry or concrete, which might form a secure foundation for an iron lighthouse. The outer cone might, it was suggested, be eventually removed without prejudicing the security of the foundation, which has, at his own expense, partially carried out his scheme in a modified form, using a cylindrical casework of iron 64 feet high and 80 feet in diameter in lieu of the proposed timber cone; but it appears by the evidence laid before the lighthouse Committee of 1845, that the Trinity House refused to sanction the lighting of his unfinished structure, and that some of its officers deemed Bush's plan to be impracticable. Mr. Bush proposed not merely a lighthouse, but an extensive asylum for shipwrecked sailors, and even the construction of a harbour of refuge at the Goodwin Sands. In connection with this scheme we may notice, though not strictly falling within the subject of our present communication, that a lighthouse erected in 1840 upon another part of the same dangerous sands by Captain Bullock. This beacon, which is intended simply as a refuge for shipwrecked sailors, and not for a light, is a conical screw-pile, of ordinary material, 64 feet high, with a diameter of 30 feet, and stands about 40 feet high, surrounded by a flag-staff 10 feet high, and supporting, near its upper extremity, a gallery in feet in height, constructed principally of sail-cloth, and capable of holding forty persons, to which access may be obtained from below by means of ropes and cleats or notches in the mast. The mast or shaft is secured to a massive platform of oak, sunk several feet below the surface of the sand, and loaded with upwards of three tons of iron ballast; and it is further supported by oblique bars of iron and chains. The mainmast or shaft of the beacon stands 30 feet above the dry sand at low water, and 17 feet 6 inches above high springs. In the gallery is placed a barrel of fresh water and a bag containing a blue flag, which is to be hoisted when assistance is required from the land, which is seven miles distant; and to render the beacon accessible to all who are likely to make use of it. In directions 'to hoist the flag' are painted in eight different languages on the sides of the gallery.

Perhaps the most curious recent invention connected with our subject is that of Mr. Alexander Mitchell, of Belfast, for constructing lighthouses and beacons entirely supported by piles, which, instead of being driven into the ground like ordinary piles, rest upon a screw, which is firmly attached to the piles, and is fitted with an ordinary screw attached to their lower extremities. These screws, which were first employed instead of mooring-anchors, are of cast-iron, and consist of a broad thin plate or share wind¬ing round a conical iron core, the diameter of the screw being from two to five feet, and the thread or share taking only one turn and a half round its axis, and having its outer edge sharp, so as to cut its way readily, when the axis is turned round by suitable means, into sand or earth, while its broad surface offers great resistance to any attempt to pull it out of its place. The great success of this invention, as applied to moorings, led to the attempt to apply it to the purpose of extending these piles, on which purpose it bids fair to become highly important, as such lighthouses may be erected where there is not sufficient depth of water to moor a light-ship, and fixed lights are always more exposed to perish by the action of wind and wave than floating lights. The first screw-pile lighthouse was commenced on the Maplin sands, at the mouth of the Thames, in 1835, by screwing into the sands the eight wrought-iron shafts, arranged so as to form an octagonal light-house, 25 feet in diameter, and already on that part of the coast exposed to the constant and motion forwards at the upper extremities, and a ninth perfectly upright, in the centre. These shafts were about 25 feet long, and were screwed 20 feet into the sand; and to the top of each shaft a lighthouse were secured upon three or four pillars, strongly braced and bound together, supporting a massive timber framework upon which is built the lighthouse, comprising store-rooms and apartments for the keepers. This lighthouse was not completed until February, 1841; but in
November, 1839, a similar structure, supported upon seven instead of nine piles, was commenced at the mouth of the river, its purpose to prevent any breakers from entering into the new port of Fleetwood, which was completed in June, 1840, at a cost of about £3000. In both these structures the supporting framework is left open to a considerable extent, as being necessary for the purpose of keeping an extended surface for the waves to beat against, and are thus protected from the violent shocks to which other lighthouses are subject. A third lighthouse of similar character was erected in Carrickfergus Bay in 1844, as a fort, for state service and labour only (Mr. Mitchell giving his services as engineer gratuitously), of only 1000 l., although the building, being used also as a pilot station, is large enough for the residence of two lighthouse keepers and their families. The station, according to the framework two heavy pilot-boats. Economy of maintenance appears to be striking a feature of this kind of lighthouse as economy of construction, that at Fleetwood having in the five years between its erection and the date of Mitchell's evidence before the committee of 1845, cost nothing for repair beyond occasional painting. It has been suggested that life-boats might be kept suspended to such lighthouses, like the pilot-boats at Carrickfergus Bay. The parliamentary report of 1845 refers to another mode of inserting piles in sand for the purpose of supporting lighthouses, the invention of Dr. Potts, as being under experiment by the Turkish authorities, of constructing hollow iron cylinders by pumping out the air from their interior, and thus forcing them into the sand by atmospheric pressure.

Some ingenious suggestions of Mr. Alexander Gordon, with regard to the method of making the lighthouses seen from the sea, and other things in the report, relate to the use of a kind of hollow iron tower or funnel in light-ships, through which the lanterns might be hoisted and lowered for trimming more safely and conveniently than when attached to a mast, and through which men might ascend when necessary to attend to the lights, secure from the effect of rough weather; and also to a plan for distributing in foggy weather, by means of revolving parabolic reflectors, the light produced by a powerful whistle, constructed like the steam-whistle of a railway locomotive.

The second of the two papers above referred to in the 'Penny Magazine' contains a notice of an important suggestion made by Captain Basil Hall in a letter to the 'United Service Journal,' in reference to revolving lights. A fixed light, if required to be seen in one direction only, may be readily mounted with a parabolic reflector, so as to show at a very great distance; but where the light is required to be seen in all directions a difficulty arises, because, even supposing twenty-four distinct lamps, each having its own reflector, to be arranged in a circle, they will, owing to the light being reflected several times on the walls of theuin the part of the horizon, leaving the intervening portions in darkness, while at the same time the light will, from being so divided and scattered, be less efficient than if it were concentrated upon a smaller surface. It is shown that the greatest advantages of revolving lights, for if, as the case is put by Captain Hall, instead of twenty-four lamps arranged at equidistant intervals round the circle, six be directed, by their reflectors, due north, six due south, six due east, and six due west, and then that part of the lighthouse upon which the four sets of lamps is mounted to cause to revolve upon a vertical axis, the four concentrated blazes of light, instead of illuminating only the four points to which they were originally directed, will light up, in succession, every part of the horizon, and that with a blaze of light six times more powerful than in the case first described. As, however, variety is essential to prevent one light being mistaken for another, it frequently happens that a fixed light must be adopted for the sake of distinction, notwithstanding its inferiority. Captain Hall suggests, therefore, that a revolving light might be made to rotate on its axis with such rapidity as to exhibit an unbroken line of light along its path, on the principle of a burning stick whirled round so as to produce the appearance of a circle of fire. If this could be accomplished, the result would, in a great measure, be the production of the line of the revolving light, be continuous in every direction.

An important improvement has recently been introduced by Professor Faraday in the ventilation of lighthouse lanterns. He has pointed out the great difficulty that has been experienced in the proper ventilation of lighthouses generally, ordinary means of ventilation, by allowing the free admission and egress of air, are inapplicable; but Mr. Faraday, having his attention directed to the subject by the first-lighthouse, has devised a method of ventilating lighthouses which has answered well, and which does not endanger the lights by permitting gusts of wind to get into the cowl. The contrivance is pretty fully described in an abstract of the paper referred to in 'The Athenæum' 1845, p. 637.

Sea-nettle. [Actinia, P. C.]

Seamen. Employment, Wages, &c., of Merchant Seamen.—The 6 & 8 Wm. IV. c. 19 repealed all former acts which regulated the employment, wages, and other matters connected with, merchant-seamen. The 6 & 7 Wm. IV. c. 19 has been repealed, (except so far as such act relates the acts thereby repealed, and except so far as relates to the establishment, maintenance, and regulations of the office called 'The General Register Office of Merchant Seamen'), by the 7 & 8 Vict. c. 112, which contains the present law relating to merchant-seamen and for keeping a Register of them. This act contains sixty-four sections: s. 2, &c. regulate the appointment of hiring seamen; s. 6, &c. assign the punishment of seamen for refusing to join the ship, or abstaining themselves from it; s. 9 fixes the forfeiture for desertion; s. 11 the periods within which wages not exceeding twenty pounds; s. 17 provides for seamen being sent home when the ship is sold in a foreign port; s. 18 regulates the supply of medicines, lime or lemon juice, salt, and other provisions for seamen; s. 22 provides in what cases there shall be a physician, surgeon, or apothecary on board; s. 19, &c. provide for a general register and record office of seamen; s. 31 provides for the disposal of the effects of seamen who die abroad; s. 36 provides that on board a British ship, and leaving money or effects not on board such ship; s. 32, &c. provide for apprenticing parish boys to the sea-service; s. 40 provides against masters of ships directing any person to be employed as a seaman in colonies or plantations, or at any other place abroad, except as herein provided; and s. 50 provides for seamen being in liberty to leave any ship and enter the naval service of her Majesty; s. 58 provides for offences against the property or person of any subject of her Majesty, or of any foreigner, committed at any port or place, either ashore or afloat, out of the dominions of her Majesty, by the master and crew; s. 61 declares to what cases this act relates.

Seamen in the Royal Navy and Impression.—It is stated by Blackstone, on the authority of Foster, 'that the practice of impressing and granting power to the admirality for that purpose is of very ancient date,' and that the present practice, is continued by a series of precedents to the present time, whence he concludes it to be a part of the common law. As impression is effected by the king's commission, the power of impressment being contained in the grant of the seamen for sea-service,' the limitations on, the 26th of March, 1846, p. 334, 5th ed., shows that the king used once to exercise the power of impressing men for the land service also, and even for his own private service, as in the case of goldsmiths. The legality of impressment is fully established, though the practice cannot be defended even on the ground of the safety of the state, until it has been shown that seamen for the royal navy cannot be procured by other means. The general rule is that all seamen are liable to impressment. There are several legal decisions as to the question who are seamen, and who may be privileged.

Volunteer seamen are induced to enter the royal navy by higher wages; and every foreign seaman who shall have served in a ship of war, a merchant-ship, or privater waters for two years during a war, is thereby naturalised. The 7 & 8 Vict. c. 112, s. 29, enacts that overseers of the poor, or other persons having the authority of overseers of the poor, in and for any district, union, parish, township, or place in the United Kingdom, may put out as apprentices in the British navy and merchant sea-service, all seamen of sufficient health and strength, with his consent, who, or his parent or parents is or are chargeable to or maintained by such district, &c., or who shall be held for alms therein: the time of apprenticeship in the case of such seamen shall be twenty-one years, or shall have served seven years as an apprentice, whichever shall first happen. Section 38 of the same act provides for turning over, with their consent, of garf apprentices, who shall have been bound to a master or service.
on shore, to the sea-service, to be employed as is provided in the case of apprentices to the sea-service under s. 32, for the period then remaining unexpired of their apprenticeship. Section 59 provided that all British ships of the burden of eighty tons and upwards, except pleasure-yachts, shall have apprentices in proportion to their tonnage, as in this section provided; all which apprentices must at the time of being bound to such vessels be below twenty-two and under seventeen years of age, and be duly bound for four years at least. Section 59 provides, 'That nothing in this Act, or in any agreement contained, shall prevent any seaman or person belonging to any vessel whatever from entering into or being received into the naval service of her majesty, nor shall any such entry be deemed a desertion from the ship or vessel, nor shall such seaman or other person thereby incur any penalty, or be liable to the discharge of such wages, clothes, or effects, or other matter or thing.'

The commerce of Great Britain gives regular employment to a vast body of seamen, and the habits and occupation of a large number of people on the sea-coast give them a relish and a capacity for sea-service. With the great increase of the commercial navy of Great Britain which has taken place of late years, and the prospect of still greater increase of commerce by the restrictions on trade being removed, we may always reckon on a sufficient number of seamen in the commercial navy to make up the deficiency in the royal navy in case of a sudden war. The apprenticeship system also is well adapted to a regular supply of young seamen. It is probable that ten or twenty thousand men might be at once drawn from the commercial navy for the royal navy on any emergency by offering them better wages, and thus the successor to the old system might be removed. To the amount of inconvenience that may be sustained by the merchant-service by the withdrawal of a great number of seamen at once is the same, whether the seamen are impressed or go as volunteers, but to the former service the inconvenience from the actual withdrawal of seamen by impressment must be added the loss and inconvenience to the merchant-service which may arise from seamen keeping out of the way in order to avoid being impressed.

Sedition (from the Latin sedicio]. It is stated that in many of the old English common law writers treason is sometimes expressed by the term Sedition; and that when law proceedings were in Latin, sedicio was the technical word used in indictments for treason, till it was superseded by the word Productio.

Sedition does not appear to be very exactly defined. It is stated to comprehend contumacious, indecent, or malicious observations upon the king or his government, whether made in words only, or in writing, or by tokens (which last term must comprehend pictures or drawings), calculated to lower him in the estimation of the community by injuring his government. All these offences fall short of treason; but they are considered crimes at common law, and punishable by fine and imprisonment.

There are also statutes against particular acts of sedition, such as seditious libels. [Law, Criminal, P. C. S., p. 176, No. 40. There are also various acts against societies established for sedition and treasonable purposes, and against sedition meetings and assemblies.

The Roman sense of Sedicio (sed or se, and itico, a going apart, a separation) is properly a disunion among the citizens, a riot, or turbulent assemblage of people for the purpose of accomplishing some object by violence or causing fear. It was included among other forbidden acts in the Lex Julia de Majestate. (Dig. 48, tit. 4.) It is often used in connexion with "politics," and "to riot," and seems to have the same significance. (Rein, Römisches Criminaledrecht, p. 522.)

SELM III., son of Sultan Mustapha III., was born Dec. 12, 1626, at Constantinople, and killed by his own brother Abul-Hamid, and Selim was shut up in the seraglio among the women and eunuchs. Abul-Hamid died April 7, 1639, and Selim then became sultan. The principal events of his reign are his remaining under the influence of Sofi, the chief eunuch, which was fatal to the state. He was deposed May 29, 1607, and Mustapha IV., son of Abul-Hamid, was elected in his place. Selim was put in confinement, and was starved by order of Mustapha, July 16, 1608, and the sultan was deposed immediately afterwards, and was succeeded by Mahmud II. (Mahmud II., P.C.S., Mustapha IV., P.C.)

SALVA, GIANNANTONIO, was born of respectable parents, at Venice, June 12, 1756, and had for his earliest instructor his uncle the Abate Giannemaria Selva, a man of considerable literary and scientific attainments. His inclination leading him to make choice of art as his future profession, he was placed in the studio of the celebrated Canova, who died in 1804, aged 72; but after he had grounded himself in drawing and the elements of painting, he passed to the study of architecture, and became a pupil of Taverna (Taverna, P.C.S.), and after leaving the studio of the celebrated Canova, with whom he visited Naples, Pompeii, Caserta and Poetum. While at Rome, he also obtained the notice and favour of his countryman the noble Girolamo Zuan, who placed him in the studio of the celebrated Mengs, and who was a liberal encourager of art. By him Selva was commissioned to embellish and fit up a salon in his palace expressly for an entertainment given to the Archduke Ferdinand of Austria and his bride; before which he had been similarly employed by the Senator Rezzonico to decorate an apartment for him, which was to have been done by Quarenghi, but that architect was then obliged to depart for Russia. (Quarenghi, P. C.) On quitting Rome Selva visited France and England, in both which countries he diligently collected information of every kind bearing upon architecture and building; and returned to Venice at the close of 1780. There, as opportunity offered, he embellished various public and private edifices among them greater attention to internal convenience and disposition of plan, setting also the example of a more sober taste in design. Among the private mansions on which he worked was that of the celebrated Comte di Canova, in which he added the Loggia della Teresia, and the Palazzo Manin, which last, however (a work of Senovino's), he only restored and altered in the interior, though it was at first intended to greatly enliven the whole edifice according to foreign designs by him, and a model which is still in existence. He also rebuilt the Palazzo Pisani at Padua. The public work to which he owes his chief reputation is the celebrated Teatro della Fenice, erected 1790-91, and his design for which was selected from among forty by twenty-nine other architects (Theatre, Théâtre, P. C.). Another structure of the same class designed by him was the theatre at Trissie, but in the execution of the work very great liberties were taken. A third theatre planned by him was never executed, but when he was some years afterwards at Florence, he found that parts of his design had been adopted for a theatre then lately erected there. To the above may be added the facade of the Casa Vigo d'Arreti, and a Casino at Padua; the Casa Vela at Verona; the facade of the church Santissimo a Udine; the facade of San Minuto at Venice, begun by Zagarini, and left unfinished by Selva, after which it was completed by Diedo. The same fate attended his last and most favourite work, the small church Del Gesti, which was finished after his death by Diedo (author of a work on the history of descriptions in Cicogna's "Fabbriche più conosciute di Venezia," and Giuseppe Boratto. Selva died rather unexpectedly, at the beginning of 1819, and therefore could not have executed, as Nugler says he did, Canova's church at Possane, the first stone of which was not laid till July 11th in that year. Two years before, indeed, he made a journey to Rome expressly to visit his friend the illustrious sculptor, and he may probably have then given the latter some hints and ideas, but beyond that he certainly had no share in the structure. Selva was also a writer upon subjects of his art; be as well as Diedo contributed to Cicogna's work above referred to; and there are also two small papers on the orders, and Chambers' 'Civil Architecture.' There is a portrait and short notice of Selva in Gamba's 'Galleria de' Letteriti.'

SEMIOTONUS, a fossil fish from the slim. (Agassiz.)

SENIUS AGER (in honor of John de Senehler, of Geneva, a vegetable physiologist), a genus of plants belonging to the natural order Crucifera. The pouch is somewhat kidney-shaped, entire at the end, or notched above and below, and almost to the middle. The seed is immediately after the flowers, and is covered with white
membranous margins. This plant was formerly gathered and eaten as a salad, but it has since been reasonably neglected, as it is acrid and unpleasant, and must require much boiling to render it eatable. It is native of Europe, North America, and Asia, and is extensively cultivated for ornamental purposes.

S. didyma, has a pouch notched by two wrinkled lobes, an extremely short style, and pinnatifid leaves. The stem is spreading, about a foot in length. The flowers small and white in long clusters. It is found on waste ground near the sea in Great Britain. S. nitricia is eaten as a salad in Egypt. As these plants possess no beauty, they are not worth cultivating except in botanical gardens.

(Don, Gardner's Dictionary; Bahning, Manual of British Botany.)

SEQUESTRATION (Scotland), (Bankruptcy, P. C. S.)

SERAPROPE (P. C. S.)

SEQUESTRATION (Scotland). (Bankruptcy, P. C. S.)

SERAPROPE MISSION. A brief account of the origin of the Baptist Missionary Society, and of the history of this, one of the most important establishments connected with it, having been given under Missions, P. C. S., p. 270, an article under this head is chiefly required to supply the omission in its proper place of a memoir of William Carey, D.D., its principal founder.

Dr. Carey was the son of the master of a small free-school at the village of Paulcraggy, in Northamptonshire, where he was born on the 17th of August, 1761. Even in childhood he was remarkable for his intense love of knowledge and ardor in its pursuit. He was apprenticed to a shoemaker at Hackleton, but becoming early the subject of deep religious impressions, he began to preach about the age of twenty, and, without entirely giving up his business, settled at Moulton, in his native county, as pastor of a small Baptist church, whence, in 1789, he removed to Leicester. It was during his residence in obscurity at Moulton that Carey wrote the work alluded to above, 'On the advantages which gentlemen may, at an important degree, to the formation of the Baptist Missionary Society; but it was not published until some years after it was written, it being found difficult to excite even ministers to a more active interest in the cause of missions. The circumstances attending the organization of the society need not be repeated here, but we may state, as an indication of the difficulties to be overcome by its first agents, especially in consequence of the opposition of the English East India Company to any efforts for the evangelization of Hindostan, that Carey and his companion, Mr. Thomas, were, before the ship in which they set sail finally left the coast of England, set ashore in consequence of threats held out in an anonymous letter which followed the captain, and were thus compelled to take passage in a Danish ship, which was not under the Company's control. For some months after their arrival at Calcutta the missionaries endured great trials, and they were at length compelled to accept engagements tosuperintend indigo-factories in the vicinity of Malda, sparing what time and money they could for the promotion of their primary object. In 1786 Carey began the work of Bible translation; and in 1799, in which year he removed to Kidderpore, he bought a press and printing apparatus. A third missionary had been sent out in 1796 to join Carey and his fellow-labourers, and he was at length received into the society, with including Mr. (afterwards Dr.) Marsham, and Mr. Ward, who had been brought up to the printing business, and to whom Carey had, before leaving England, expressed a hope that the mind of any of their construction of the necessary which might arise for his practical knowledge of the art, were rent out. As the East India Company would not allow them to settle as missionaries in their dominions, the mission establishment was, about the time of their arrival, removed from Kidderpore to the Danish settlement of Serampore (Serampore, F. C., p. 259), where for many years the work of translating and printing the Bible continued. Various portions of the various languages of Hindostan was carried on with surprising energy. It appears from the appendix to a 'Tenth Memoir respecting the Translation of the Sacred Scriptures into the Oriental Languages, by the Serampore Brethren,' which was published in London in 1834, that the translation and printing of the New Testament into Bengali was completed in 1801; and that between that date and the month of July, 1832, the whole of the Bible was rendered into this language, and after the whole or part into at least thirty-nine other Oriental languages or dialects, 212,665 copies of the New Testament and other portions of the Bible having been issued during that time from the Mission press, in addition to many prints for the British and Foreign and some other Bible Societies. During the same period a great number of religious tracts and miscellaneous works were also produced, in several different languages, including a Bengali map of India, a grammar and two dictionaries, a semi-weekly newspaper, and a Youth's Magazine, in Bengali and English; and, in Bengali alone, several large volumes of Government Regulations, a History of India, a transit newspaper of Goldsmith's correspondents, a Treatise on Anatomy, intended as the first volume of an Encyclopaedia of the Sciences, a Treatise on Geography, and a translation of the Pilgrim's Progress. The list of works in all languages, native and foreign, and other languages comprises also many important books.

In these great undertakings Dr. Carey was the chief director, while a very large proportion of the actual literary labour also rested on his shoulders. In addition to the duties of principal professor of oriental languages in the college of Fort William at Calcutta, from its establishment in 1800 until its virtual abolition by the discontinuance of the fees of the university of the town, he was also awarded a pension from government. He died at Serampore on the 8th of June, 1834, in his seventy-third year, leaving some autographic memoranda which have been used by his nephew, H. H. Wilson, in the Rev. Eustace Cary's History of India, published in London in 1836, to which a portrait is prefixed. In a biographical sketch by his son Jonathan, incorporated in the memoir referred to, it is observed that in all objects connected with the general good of his adopted country, Dr. Carey took an active part, and that 'he prepared, under the direction of a noble lady then resident in India, the prospectus of an agricultural society in the East, to which was united an horticultural society, of which he was a member, and in the affairs of which he took a lively interest, till his last illness; and he had the gratification to see that the society became at length the most flourishing and interesting society in the East, in which gentlemen of the first rank in the country, united, and which still continues an eminently useful and flourishing institution.' Botany was, indeed, a very favourite study with Dr. Carey, whose share in the publication of Rumphius's Elzas Indica, and of Parkinson's Roxburgh, P. C., p. 197. 'In this Asiatic Society,' continues his son, 'he also took an active part; and for many years, up to his death, was one of the members of the committee of papers, and afforded considerable information, and in various ways promoted the general interests of the institution.' At his death, he adds, 'the Bishop of Calcutta, in a speech, passed the highest encomiums on the character and talents of Dr. Carey; and a minute was recorded expressive of the loss sustained by the society, and their regret at the removal of one of its most excellent members.'

From 'Remarks on the Character and Labours of Dr. Carey, as an Oriental Scholar and Translator,' by H. H. Wilson, Esq., Boden Professor of Sanscrit in the University of Oxford, which is also appended to the 'Memoir' by Eustace Carey, we select the following sketch of his more important and legitimate labours. 'At the time when Dr. Carey commenced his career of Oriental study, the facilities that have since accumulated were wholly wanting, and the student was destitute of all elementary aid, With the exception of a few works of Dupa, the natives of India as sacred and classical, such as the Arabic and Sanscrit, few of the Indian dialects have ever been reduced to their elements by original writers. The principles governing the formation of their construction of the necessary, which might arise for his practical knowledge of the art, were not yet set out. As the East India Company would not allow them
the familiar use of their vernacular inflexions and idioms, the natives of India never thought it necessary to lay down rules for their application; and even in the present day they cannot exactly define them, or, by providing them, introduce correctly the dialects which they daily and hourly speak. Europeans, however, are differently circumstanced. With them the precept must precede the practice, if they wish to attain to a correct composition of a foreign language. But when the Oriental languages first became the subjects of investigation, these precepts were yet to be developed, and the early students had, therefore, as they gathered words and phrases, to investigate and to apply them to the rules of grammar, as they formed in frame, as they proceeded, a grammar for themselves. The talents of Dr. Carey were, he adds, "eminently adapted to such an undertaking." Mr. Wilson goes on to state that Dr. Carey "was a man of genius of a different order from any of his contemporaries. His mind was the only authority for the language of the Sikh nation; and although, he remarks, "he must concede to Halked the credit of first reducing to rule the construction of the Bengali tongue, yet by his own grammar and dictionary, and other useful rudimental publications, Dr. Carey may claim the merit of having raised it from the condition of a rude and unsettled dialect to the character of a regular and permanent form of speech, and as an instrument of a literature, as capable through its intimate relation to the Sanscrit, of becoming a refined and comprehensive vehicle for the diffusion of sound knowledge and religious truth." Some of the works he mentions as illustrative of the point of view held of the Sanscrit grammar, for example, comprising upwards of 4000 quarto pages, and the Bengali and English Dictionary, published in 1815 and 1825, in three volumes, upwards of 2000 quarto pages, and about 50,000 words. An abridgment of the latter work, prepared by Dr. Marshman under the supervision of Dr. Carey himself, was published in 1827 in one thick octavo volume. One of the extensive literary productions of the Serampore press was 'The Ramáyana of Valmíeki, in the original Sanscrit, with a Prose Translation, and Explanatory Notes,' edited by Drs. Carey and Marshman, of which four quarto volumes were published, in 1806 and subsequent years, under the sanction of the Asiatic Society and the Council of Fort William College, but which, unfortunately, was never completed.

It may, at first sight, excite some surprise that the Serampore missionaries should, in some instances, have issued translations in languages or dialects with which none of them were fully acquainted. In this department, observes Mr. Wilson in explanation, 'Dr. Carey took a leading part, and it was in connection with this duty that he entered upon the difficult task of the translations that he added to his great proficiency in Sanscrit and Bengali, a knowledge of those dialects whose elements he first investigated. Possessed in this way, he states, 'of at least a superficial acquaintance with the dialects, and of Sanscrit for the whole family, and endowed with a genius for philologica! investigation, Dr. Carey was peculiarly qualified to superintend the translation of the Scriptures into a number of cognate languages. It may be granted, that, in combination with his colleagues, he carried the project as successful an issue as could be expected from the bounded faculties of man.

In the above sketch of the labours of Dr. Carey frequent allusion has been made to Joshua Marshman, D.D., perhaps the most eminent of his colleagues, but of whose particular share in the great undertakings of the Serampore Brethren, as the brother of proponents among whom the most prominent often styled themselves, it is not necessary to give any account. From a statement in the 'Baptist Magazine' for April, 1838, it would appear that he was born in 1768, and came to India in 1797. In 1826 he visited England on the subject of the disagreement between the Serampore Brethren and the Baptist Missionary Society, which led to their separation in the following year; he acted as their agent, returned to Calcutta in 1828, and resided there for thirteen years, until 1841, when he returned to England in 1828 on the same occasion. In this disagreement, which arose about 1817, the uncompromising and somewhat impracticable spirit of this otherwise excellent man, appears to have had considerable weight. In 1820 he was placed at the head of the printing-office of the Serampore Mission, a task which he performed with great success until his death on the 5th of December, 1837, a few days previous to which event arrangements were concluded in London for the re-union of the Serampore Mission with the parent society, and for retaining him in the superintendence. In a sketch of his character at the end of the first volume of Dr. Cox's 'History of the Baptist Missionary Society' he is said to have been possessed of great mental power and energy, and of a strong disposition to controversy, and of much warmth. Dr. Marshman's name is especially known by his controversy with Rammohun Roy (Rammoukor Roy, J. C. S., p. 464), who distinguished himself in the publication of 'Amrita Bazar Patrika,' a most interesting and able criticism upon idolatry, and by the publication of a work entitled 'The Precepts of Jesus, the Guide to Peace,' in which, while admitting the precepts, he expounds the miracles of Christ.

Of the history of the Serampore Mission itself little more need be said. The leading facts are given under MISSIONS, p. C., to which we may add, that although Dr. Carey had been selected as an asylum from the opposition of the East India Company, the missionaries were not disturbed when, shortly after their settlement, the place came into the hands of the British government. Since the death of Dr. Marshman the newly-established Missionary Society at Calcutta has been under the name of the 'Friend of India,' a periodical issued by the Serampore missionaries, which were subsequently republished in London, in 1822, in a separate volume, entitled 'A Defence of the Principles of the Bible.' In 1817 the first volume of the 'Friend of India' appeared, and in 1824 another London edition of Rammohun Roy's work, illustrated with portrait of the author, and containing replies to Dr. Marshman.

SERAPHINE, a musical instrument of the keyed kind, recently invented, and may be described as a small organ, in which very short, thin, and narrow steel bars, or springs, put into vibratory motion by means of a bellows acted on by the foot, are used instead of pipes. The principle on which this instrument, as well as every variety of it, is constructed, has been explained under the head ACCORDION, C.S., and under the term CONCERTINA, P.C.S. Nothing therefore remains to be added, except that the Seraphine is in the form of a chippot, about thirty-seven inches high, forty wide, and twenty-two deep. Its compass is five octaves, including all the semitones, and it is played on in the same manner as any other keyed instrument. It combines the advantages of both organ and pianoforte, by affording the means of prolonging the sounds, and of increasing the volume of sound by means of these by the more or less pressure of the fingers and the bellows: while further power of augmenting the loudness is obtained by a pedal acting on a swell. The effects to be drawn from so small an instrument are therefore limited, but they are praiseworthy as various; and its convenient form, moderate price, together with its invaluable property of standing in tune—perhaps we might say of never going out of tune—are such additional recommendations of the Seraphine, that, we are
PERSERULIUM, a genus of annulose (?), from the Silurian strata of Salop, etc. (Marchion.)

SERIFALCUS, a genus of grases belonging to the tribe Festucineae. It has unequal herbaceous many flowered glumes, the lower from 3 to 5 nerved, the upper 7 to 9. The flower is oblong and triquet. The outer pairs with a short seta formed on three nerves from below the tip. The styles lateral below the summit of the fruit. The epipaleata navel at the top.

S. acutus has a loose panicle slightly compound, the simple peduncles about equalling the oblong glabrous spikellets, the flowers at first loosely incurved, afterwards distinct, about as long as the panicle, the outer paler not overlapping the next flower. The flower is large and downy, the leaves hairy with nearly smooth sheaths. It is native of Great Britain.

S. rotundus has a close or elongated erect panicle usually simple, the epipaleata glabrous ovate and somewhat compressed. The midrib of the glumes and palea scabrous towards the top, the leaves and sheaths slightly hairy. It is a common species in sandy places in south of Great Britain. (Wallingford, Manual of British Botany.)

SERICORNES (Insects), the third family of Penta-

S. centauri Coloptera. They have four palpi, elytra which cover the abdomen, and antennae, which are for the most part equal throughout, or smaller at the extremity. The Linnean genera Brachystomus, Elater, Lepismus, and Pityius belong to this family, as also do Melophyris, Cerura, and Cabio. The family Pityius is the one which have done so much damage among collections of natural history.

SERVITUDES (servitute). A servitude in the Roman law signifies that the owner of some particular property is bound in respect to some other person, simply as such person, or as being the owner of a particular property, either not to do certain acts to his property, or to allow that other person to do some particular acts to the property. The rights of this kind which one person may have to the property of another person are also called servitudes. The thing which is the object of the servitude is said service, to owe a servitude. It follows from the definition that a man can only have a servitude in another man's property, and in a corporeal thing; and that the owner of the servient property is not required to do any thing in order that the other may enjoy the servitude (Dug. 8, tit. 1, s. 16): his duty consists in not doing, and in permitting to do. The servitude must be a thing which gives some profit or advantage to him to whom it is due; and it gives him a right in re. In case of doubt there is no presumption in favour of a servitude; the term is those it is established are to be strictly interpreted, and its existence, and the rights attending it, in the way least prejudicial to the owner of the servient property.

A man must be the owner of a property, or have a dominium utile in it, in order to be able to enunciate it with a servitude awaiting on it.

Servitudes were either a right belonging to some particular person, which ceased with his life, unless they were granted to his heirs, and were called servitutes personalium or servitutes onerum; or they were attached to a piece of property, and were called servitutes rei, or servitutes praeedituum or servitutes servientium. Personal servitudes were in some cases called servitutes usurae, servitutes servorum; and servitutes servorum atque servorum. (Servitude, servitute, servitor, servitus.)

FRAZEL SERVITUTES were either Servitutes Urbanae or Rustices. They were Urbanae if the property which was entitled to the servitude was a building: they were Rustices, if it was a piece of ground. There was no limit to the number or kind of servitudes of this class which might be established. Those servitudes Urbanae which were of ordinary occurrence were such as follow: Servitites oneris servientium, the right which a man has to let his building rest on the building, the wall, or the gable which belongs to another's; his right to be indemnified for the damage which that causes him; Servitites servorum, the right of fixing a man's chimney in his neighbour's wall; Luminaria servientium, the right of a man's making windows or openings in his neighbour's wall, or in a common wall, in order to light his building; Servitites servorum, the right of opening holes or windows in a man's own wall, which holes or windows look into his neighbour's property, in such cases as would be unlawful without the existence of the servitude; Servitites servorum, the right of opening windows or openings in his neighbour's wall, or in a common wall, in order to light his building; Servitites servorum, the right of opening holes or windows in a man's own wall, which holes or windows look into his neighbour's property, in such cases as would be unlawful without the existence of the servitude; Servitites servorum, the right of opening windows or openings in his neighbour's wall, or in a common wall, in order to light his building. The common wall is the act of the subjects and the servitudes of the subjects of the state, and the servitudes of servitute are the act of the state, and the servitudes of servitute are the act of the subjects. It is the subject of the state, and the servitudes of servitute are the act of the state, and the servitudes of servitute are the act of the subjects. It is the subject of the state, and the servitudes of servitute are the act of the state, and the servitudes of servitute are the act of the subjects. It is the subject of the state, and the servitudes of servitute are the act of the state, and the servitudes of servitute are the act of the subjects.

Servitudes might be established by contract, at least in the case of a negative servitude, that is one by which the owner of the servient property was bound not to do certain things; by testamentary disposition; by prescription in the Roman sense; and in some other ways.

Servitudes might cease by the party entitled to them renouncing them by express words or tacitly: in the case of praevidens servitude, by one person becoming owner of the two properties, but not unless the whole of the servient or the whole of the dominant property was acquired; and in some other ways.

The actions that a man might have in respect to servitudes need not be particularly mentioned here, as the Roman forms were peculiar, and the object of this article is simply to show the general nature of servitudes, and the particular servitudes which may be compared with some of the easements and rights of
the English system. [Wat, P. C.] The personal servitudes of the Roman law do not correspond, except in some few cases, with any thing in the English law, except limited enjoyment. [Uxurxurius, P. C.]

The subject of the Roman servitudes would require a long exposition to be treated fully. A good outline is contained in [Wat, P. C., De Dominio, ed. L., p. 269, f. 36 ed.; and in Mackeldy, Lezheb, &c., ii. § 274, 15th ed.]

SESLERIA, a genus of grasses belonging to the tribe Seclerian. It has a spiked panicle, sessile spikelets tiled all round, the glumes from 2 to 6 flowered, nearly as long as the spikelet. The outer paleae keeled and membranaceous, with a scarious margin ending in 3 or 5 points, the dorsal palea evanescent.

S. sessilis has an ovate slightly one-sided spike, the outer palea terminating in 4 teeth, the dorsal palea rough, with a short excurrent point, the leaves shrew, with a minute rough point. The roots are tufted, the stem from 6 to 12 inches high. The spike about 4 inches long, and of a bluish-purple colour. This is the only British species. It is found chiefly on mountains.

S. quenensis is the Ficus quadridentata of Humboldt and others. Humboldt tells us that it is very poisonous.

(Lindley, Flora Medica; Babington, Manual of British Botany.)

SESSION, COURT OF, is the Principal Tribunal of Civil Jurisdiction in Scotland. As at present constituted it dates back to the year 1532; but it was then reconstructed on the basis of institutions which had existed at a much earlier period. The early records of the Scottish Parliament show that the administration of justice, which in those times was mixed, with the legislative functions of that body, was often deputed to committees. These were termed Domini Auditores, or Domini ad Querelas, and received other like titles. We find their committees and their functions placed on a quite different footing in 1503, when a permanent body received the designation of The Daily Council. It is worthy of observation that these incidents in the history of the court usher in the absence of jury trial as a fundamental feature in the Court of Session, while in early times it is known to have belonged to the courts of the inferior judges. Parliament being the high judge of the nation, it would be an anarchy that a committee of that body should act through the aid of a jury. The number of the court as finally established in 1592 was fifteen, the usual number of a Scottish jury in former times, and still the number of a jury in a criminal prosecution.

There was then a Lord Chancellor of Scotland, whose functions in some degree resembled those of the same official in England. He presided over the Court of Session, and his judicial functions gradually came to be absorbed in those of the judges, who presided in union with English law. It was deemed necessary to retain a separate chancellor of Scotland, and the great seal to be appended to private documents for that part of the country being committed to a keeper, the court was presided over by the lord president, or a deputy appointed in his absence of the chancellor. In 1806 the Court of Session was divided into two divisions: the head of the court, the lord president, who is also now lord justice-general or head of the supreme criminal court, presides in the first division, and the lord justice clerk, or deputy head of the criminal court, presides in the second. In 1815, trial by jury in civil cases on the English system was introduced in Scotland. A separate tribunal was established for jury cases, presided over by a Lord Chief Commissioner, but in 1830 the practice of jury trial was united with that of the Court of Session. It is still only adopted in a limited number of cases, and is far from being popular or satisfactory. The Scottish system of pleading is ill adapted to it, and no means have been found of carrying it through with the promptitude and precision which mark the English practice. Its chief benefit has been in enforcing the separation in all pleadings of the facts stated from the law applied to them. In 1830 two separate courts of limited jurisdiction and small practice - the Admiralty and Commissionary Courts - were absorbed in the Court of Session, and the number of the judges was reduced at first to five, and then to fifteen to thirteen. By this measure the court was made to assume less the form of a deliberative assembly acting through a majority, which was the particular characteristic of the court before the reforms. The work was thrown largely upon individuals. By the act of 1830 (2 Geo. IV., 1 Will. IV., c. 68), as carried out by a later act (3 & 2 Vict. c. 118), eight of the judges, formed into two courts of four judges each, sit in the two divisions of the Inner House, where each division forms a court of second instance. The other five judges are called the Lords Ordinary, and each sits on his own, as if he held a separate court, which, in reference to the court of further resort is called the Outer House. The judgment of a lord ordinary on a closed record is final in the outer house, but it may, within a limited time, be carried by appeal to a court of the Inner House, under the provisions of the act of 1830. The Inner House, where it may be pleaded again on the record as made up in the outer house. The system of pleadings has of late years been much abbreviated and systematised, and this, added to the reduced number of judges who sit and give their views on each case, has materially abbreviated the procedure, although it is still the practice for the whole court to be assembled and consulted in difficult cases. The Supreme Court of Session is the court of final appeal on questions of civil right. It gives remedy when other courts whose functions it is to regulate the rights and duties of certain sections of the public as members of a particular class - such as courts of real and ecclesiastical exceed their powers. The proceedings before the Court of Session in relation to the church courts, were the cause of the great secession from the Scottish church in 1685 (This Church, P. C.). As every description of civil question between man and man in Scotland can be competently decided before the Court of Session, it is usual in England to speak of it as a court 'both of law and equity;' but this is a distinction proceeding from incidental circumstances and is no necessary or proper systematic division of the administration of the law. The Court of Session have the authority enjoyed by the equity courts in England, in the appointment of receivers, the supervision of the protection of property, or of persons where discretionary protection or direction are necessary, and there is no person competent in ordinary course of law to act. In 1839 (2 & 3 Wm. IV., c. 30), the judges of the Court of Session were appointed according to a certain rotation to perform the duty of judges of the court of justice in matters criminal, and those of judges of the court of exchequer, where the duty is to act as a court of quarter sessions of the peace. This change was made in the system of rotation in the performance of the duty of courts of which certain of the lords of session had previously been permanently appointed the judges. By an old practice in Scotland each 'Senator of the College of Justice,' as the judges of the Court of Session are officially called, takes the title of lord.

SESSIONS, the criminal jurisdiction of justices in general and quarter-sessions, is the subject of c. 38, which enacts 'that after the passing of this Act neither the justices of the peace acting in and for any county, riding, division, or liberty, nor the recorder of any borough, shall at any time sit as a jury on any indictment or other accusation of a person or persons or any treason, murder, or capital felony, or for any felony which, when committed by a person not previously convicted of felony, is punishable by transportation or transportation and fine, or for any other felony when committed by a person not previously convicted, to be tried by the justices of the peace, or a court of quarter sessions, or any person appointed under the 18 heads contained in the first section of the act. The second section provides that any judge of the supreme courts at Westminster, acting under a commission of oyer and terminer and gaol delivery for any county, may try in writing or writing by certiorari or other process directed to the justices of the peace acting in and for such county, &c., or to the recorder of any county within the same county, commandments of the said justices and recorder severally to certify and return into such court of oyer and terminer, &c., all indictments and presentments found or taken by such justices or recorder of offences which after the passing of this act they will not have any jurisdiction to try, and the several recognizances, examinations, and depositions relative to such indictments and presentments; and, if necessary, by writing or writing by Habeas Corpus may cause any person in the custody of any gaol or prison, charged with any such offence, to be removed into the custody of the common gaol of the county, that such offences may be tried under the said commission. The fourth section empowers any court of general or quarter-session or adjourned quarter-sessions to try all crimes and misdemeanours of which a court of common law or a court of admiralty is not competent to try and which may sit apart for the better despatch of business, in the manner and subject to the conditions in this section mentioned. The word BALKANAI, is remembered, not for his literary merits, but for the extraordinary fact that he, a person of very small talents, was for a time the successful rival of one of the greatest poets of the nation. The particulars of his
history, with specimens of his works, may be gathered from various parts of Scott's edition of the works of Dryden. Settle, born in 1618 at Dunstable, was entered a commissary of Trusty College, Oxford, in 1666, but left the university without a degree, and came to London as a literary adventurer. The introduction of his unscrupulous patron, the laureate of his tragedy of 'Cantilyea,' and the prolific Boethus, destined to humble Dryden, eagerly adopted the new dramatist as his instrument. Settle's next tragedy, 'The Emperor of Morocco,' introduced his unscrupulous patron, the laureate of his tragedy of 'Cantilyea,' and the prolific Boethus, destined to humble Dryden, eagerly adopted the new dramatist as his instrument.

of his history, the very little is known respecting the population. It is stated that a peculiar language is spoken by them. Their number, which formerly amounted to a thousand families and more, has lately been much reduced by the incursions of the Khan of Kundus, who has subjected Shagnan to a dependency on his authority.

(\textit{Wood's Journey to the Source of the River Oxus.})

\textbf{SHAGAN S. [LEATHER., F. C. S.]} \textbf{SHAGALLAS. [AUDITUS, P. C. S.]} \textbf{SHEATHING. Under SHIP-BUILDING, P. C. p. 386.} is given a notice of the introduction of copper sheathing in the British navy, and of Sir Humphry Davy's experiment for protecting the copper from the destructive action of seawater, as well as of the unexpected result by which his invention was rendered nugatory.

Owing to the great expense of copper sheathing, which has the effect of limiting its use in mercantile shipping, many attempts have been made to substitute for it either other metals, or alloys in which it is mixed with cheaper metals, or with metals that might increase its durability. In noticing several of these, Hebert, in the 'Engineer's and Mechanic's Encyclopaedia, art. 'Sheathing,' refers to a patent obtained by Mr. Robert Mushet (in what year he does not state), for 'certain mixtures or compositions of metals or mixtures of copper and alloyed copper, so as to render it more durable when employed as sheathing to ships' bottoms,' in which he directs that 100 lbs. of copper should be alloyed either with 2 oz. of the extract of zinc, 4 oz. of the extract of antimony, 8 oz. of the extract of arsenic, or 2 oz. of grain; or instead of using one of these separately, that the whole he used together in the proportion of half an ounce each of the zinc and tin, 1 oz. of the antimony, and 2 oz. of the arsenic, to 100 lbs. of copper. By these mixtures, Mr. Mushet states that the copper is rendered much more cohesive and firmous in its texture, and the corrosive effect of the sea-water is in a great measure prevented. We give an exact copy of the patent, and by the proper mixture of copper and metallic zinc, we are reduced to one fourteenth of the weight in the sheets.

Down to this time Settle had been a trusted servant and pamphleteer of Shaftesbury and the other whig leaders; and in November, 1680, he superintended with much approbation the laying of the first stone of the new church of St. Paul's. Beauforts afterwards left for ever suddenly changed his party, recanting his political heresies in a narrative which he published in 1683. By this change he perhaps preserved for the time his place as poet laureate for the city, and writer of verses for pageants and other civic festivities; but with the revolution his prospects were completely blighted. Although he retained his place as city-poet, he was reduced to great poverty. He had literally to suffer the fate satirized on by his own pen. Settle's final error in politics shows at Bartholomew fair in Smithfield; and in one of these he actually performed in person the part of the Dracon slaughtered by St. George, a fact which Pope has cited as a proof that Settle had become a Jacobite. In 1696, in the reign of his Julio, he was received into the Charter-house, and died there in 1723. He was the author of sixteen original plays that were printed, and of a good many occasional and political pieces. Mr. C. T. C.

\textbf{SHAEFF [Tunis. P. C. p. 309.]} \textbf{SHADOWS, PROJECTION OF. [PERSPECTIVE. P. C. p. 499, &c.]} \textbf{SHAGAN is a country in Asia, situated in the Upper Valley of the river Oxus, where that river has not yet left the mountains, which enclose the upper part of its course. It lies between 37° and 38° N. lat., and between 70° and 72° E. long., but its exact boundaries are imperfectly known; the river Oxus which runs along its southern and western boundary, divides Shagan from Badakshan. As the bed of this river in these parts, where it is called Panj, is several thousand feet above the sea-level, its course is extremely rapid, which renders the access to Shagan from this side very difficult, and for the greater part of the year impossible. The country is traversed by numerous elevated ridges, which are covered with snow for the greater part of the year. These ridges are at their eastern end connected with the immense mountain masses which surround the elevated table-land of Fannir, on which the Oxus originates in the lake of Sir-Kul or Sir-Kul, above the mountain pass of Fatir, 150 miles above it. For the description of this inland place, the province of iron, there should be as much as 5 inches of zinc to 100 inches of iron, and smaller plates of zinc in the proportion of 3 inches to every 100, should be applied to the inner surface of the iron. All other tapping parts of the iron vessels also applied under the heads of the spikes or bolts used in
fastening the sheathing; and the heads of the nails employed are made hollow, and filled with melted zinc. This method is said to have been found effectual in a vessel which had been two years at sea, the corrosion or oxidation of the metal being almost entirely prevented, and the ship returning with a bright and clean surface.

SHEPHERDING by has masting small observed considerable in the natural order of the funnel-shaped corolla, a dry fruit, crowned with the lirip of the calyx, which is 6-toothed.

S. arcuata, corn-field madder, is the only species. The stem is a decumbent, branched, square, and leafy. The whole plant is rough and hairy. The leaves are 6 in a whorl, acute, and obovate lanceolate; the flower is blue, in a small sessile terminal umbel. It is found on sandy soils, in Great Britain and Ireland, and the Crimea.

The seeds only require to be sown in the ground in an open situation.

(Don, Gardener's Dictionary; Babington, Manual of British Flowering Plants.)

SHERIFF (Scotland). In Scotland the duties of the sheriffs are not, as in England, almost entirely executive. He exercises an extensive judicial authority, and a large portion of the business of the sheriff is of a purely judicial character. The sheriff is the judicial officer of the county, and is administered by the sheriff's court. The sheriff is also ex officio the administrator of the laws of the county, and is charged with the management of the county's finances.

In Scotland, the sheriff is an officer of the executive branch of government, and has the power to enforce the laws of the country. The sheriff is also the highest authority in the county, and has the power to grant or deny the issuance of any warrants or other legal documents.

The sheriff is elected by the voters of the county, and serves a term of years. The sheriff is responsible for the enforcement of all laws in the county, and is charged with the management of the county's finances. The sheriff is also the administrator of the laws of the county, and is charged with the management of the county's finances.
The act referred to, prescribes that the sheriff of each county shall have power and authority of abolishing all those remains of the feudal courts of Scotland which were hereditary, or in any other shape the nature of property; of bringing all judicial offices within the appointment of sheriffs, and to the exclusion of all other persons; and of conferring upon sheriffs power and authority over the sheriff-substitutes. This was in conformity with old practice, by which the sheriff, who might not himself be trained to the law, generally appointed a legal practitioner to act as his substitute. At the present day, the legal practitioner is known as a conveyancer; in every large county, in the larger towns there are two or more. Both the sheriff and his substitute are lawyers, but the latter is the local resident judge, the former generally frequenting the courts in Edinburgh, while the sheriff acts as such where the business of his office is the most important, and making occasional visits to his county. By the Jurisdiction Act it was provided that each sheriff should reside in his county during four months in each year. This provision fell into disuse, and it came to pass for such sheriffs as continued to practise at the bar to remain in Edinburgh, while the greater portion, who had given up or had not obtained practice, resided at their county-seats, or wherever choice or convenience dictated. In its time the law, like the other laws of the time, was in a state of animadversion by the friends of law reform, and a wide difference of opinion was expressed on the matter, some maintaining that the sheriff as well as his substitute ought to have an effectual period of residence in his county. In the case above cited, the former (who is styled Sheriff Depute) in Edinburgh 'was in some degree countenanced by high legal authorities, who consider the attendance of the sheriffs-depute in the court of session' during the sitting, 'to be more useful than anything, to a great adherence to the statutory rule.' It has been supposed that such an attendance tends both towards a higher degree of legal learning in the sheriffs and to uniformity of practice being promoted by those who are continually consulting each other. It was very clear, however, that it was disadvantageous to the public that there should be any of those judges who neither reside within their counties nor at the fountain of Scottish legal learning in Edinburgh, and by the 1 & 2 Vict. c. 119, it was enacted that each sheriff appointed after the 31st December, 1838, shall remain in attendance on the court of session, but shall hold eight courts in his county during the year. The sheriffs of Edinburgh and Lanark are exempted from attendance on the court of session, in the understanding that the business of their respective courts is sufficient fully to occupy their time. It may be mentioned that many law reformers, in order to secure the full and effective effect of the sheriff-substitutes, have suggested that these men should be paid salaries greater than the others ought to be. The incumbents receive much higher salaries than the other sheriffs, and have their time fully occupied. It has been held that, in regard to the other officers of the crown, there is no reason why a maxim like that should not be applied to them, that it is a matter of what the others ought to be. The incumbents receive much higher salaries than the other sheriffs, and have their time fully occupied. It has been held that, in regard to the other officers of the crown, there is no reason why a maxim like that should not be applied to them, that it is a matter of what the others ought to be. It has been held that, in regard to the other officers of the crown, there is no reason why a maxim like that should not be applied to them, that it is a matter of what the others ought to be. The incumbents receive much higher salaries than the other sheriffs, and have their time fully occupied.
The population of Shikarpore, in 1840, consisted of about 30,000 individuals, of whom about two-thirds are Hindus, and the remainder Mohammedans, inclusive of Afghans and Sindis. The Hindus carry on all the trade, while the cultivation and mechanical arts of almost every denomination are in the hands of the Mohammedans.

The country round the city is low, and admits freely of irrigation from the inundations of the river Indus by means of small nullas, or water-courses, leading from the Sinda Canal. This canal was made by the Mogul emperor for the purpose of navigation and irrigation, and is, in its present state, only navigable from the end of April to the beginning of October, as it has been allowed to chock up at its mouth, and has generally got out of repair. But it is supposed that at the flood-time it may be rendered navigable for several months of the year. The soil in the vicinity of the city is alluvial, and produces rich crops of rice and jowar.

A few articles are manufactured at Shikarpore, but not to any extent, except coarse cotton-cloth, silk-cloth, and Sindibags. There are also several dyeing-houses, in which cloth made in some of the neighbouring places is dyed and prepared for the market; and there are some paper-mills. This town is the centre of a considerable trade. The most convenient commercial road between Hindustan, Afghanistan, and Persia, runs through it, and leads to the Bolan Pass, which, in spite of its formidable aspect, is much safer than the other roads which connect the valley of the Indus with the land of Iran, and this safety has been greatly increased since the British have got possession of the province of Sind, and have suppressed the predatory incursions of the Murries and Dzongies, two Beloochee tribes who inhabit the mountains contiguous to the pass. The Bolan Pass is also accessible all the year round, and a good road leads from it to Kandahar, and thence to Persia. Shikarpore is as it were built at the opening of this place.

European and Indian goods are brought to Shikarpore by three different routes. From Calcutta they ascend the Ganges, and are taken to Louliana, whence they go down the Sinda Canal, and thence to Shikarpore, passing through Kyprope. Some of them go from Louliana to Lahore and Mooltan. These imports consist of raw Bengal silk, ivory, cochineal, spices of all kinds, coarse cotton cloth, raw Chintz, and silk manufactures, hemp, flax, cotton, net, metals, groceries, druggs, indigo, opium, saffron, and dyes. The British textiles fabrics which reach Shikarpore by this route are red-dyed cotton cloth, white cotton cloth, partly-coloured cotton cloth, long cloth, glazed chintos, printed, bleached and unbleached cottons, red and white cottons, yellow cottons, Juggermat muslin, black velvet, sheathing cloth, and coloured coarse broad cloth.

The second commercial road connects Central Hindustan with Shikarpore. The goods are brought to Pulse in Marwar, situated not far from the Aravalli range, and are taken through Jussumure and Kyprope to Shikarpore. Only a few articles reach that place by this road, especially sugar, opium, spices, and groceries.

The same articles with European goods are sent from Bombay to Shikarpore by way of Kurachee, a sea-port of Sind, west of the Indus. From this place they are transported by land to Schwim and Larkhan, and then reach Shikarpore. The returns of Shikarpore to British India consist of the produce of the country, especially rice, glue, hides, and wool, which are brought from Afghanistan are also exported, and dried fruits.

The exports from Shikarpore to Kandahar and Persia (Herat) consist of Indigo, beche, metals, coarse and fine cotton cloth, silk, muslin, pepper, rice, wines, quinine, muslin, and coarse silk cloth, silk manufactures, spices, raw cotton, coarse sugar, opium, beche, shales, embroidered home clothes, and grain. The returns consist of turquises, raw silk, manufactured silk from Herat of various kinds, dried fruits (prunes, dried black grapes, walnuts, dried apricots, almonds, and dates) in great quantities, tinned thread for embroidery (from Jollanabad), broken copper and brass vessels, madder, saffron, safflower, gum salop from Herat, manag, a dye prepared from the walnut-tree, dried mint, cardaw.% year, as many as 240,000, according to the communication of Ampére, were seen in North America. On the night of November 13, 1854, vast numbers were again observed in America; and on the same day of the same month in the years 1836, 1859, and 1868 the display of meteors in different parts of the world was remarkably numerous. Professor
Quidnix, at Brussels, observed that during the year 1838, 1839, and 1840 the shooting stars occurred on the nights of the 8th and 10th of August more abundantly than on any other nights of the year except the 12th or 13th of November; and it has been observed that the nights about the 2nd of January are singularly favorable. The months of December and January are periods at which the phenomena are, in most years, very frequent. The attention of astronomers has, however, been particularly directed to the 8th of August and the 12th of November as the times at which the recurrence of the phenomena is most probable; but it must be admitted that during the four or five last years the shooting stars have not appeared to be more numerous on those nights than on many other nights of the year.

With respect to the use of shooting stars as means of finding the differences between the longitudes of terrestrial stations, the idea was first proposed by Dr. Maclay, the astronomer royal, and it is obvious that, as their appearance or disappearance is instantaneous to persons stationed at different places, if it can be ascertained that a meteor observed by persons so situated is the same, the observations of the same meteor in the sky utilized. The first attempt to ascertain a difference of longitudes by such observations was made in the United States of America in 1825; seven simultaneous observations were made at Philadelphia and New York, in the month of October, 1826, and the 3rd of November in that year; and the mean of the differences between the times of observation at the two places gave a result which agreed within 1° (2) (in time) with the distance (2) of longitude between those places, when determined by other methods. (Silliman's Journal, October, 1840.) On the 10th of August, 1838, twelve simultaneous observations were made at Alta, and the same nights, within the same difference (28° 07' in time) between the longitudes of those places, which agrees within one second with the former determinations of that difference.

Again, in the same year, the observed times of the first appearance of the meteors in London and in the United States were employed in determining the distance between the meridians of Rome and Naples; and though, on comparing the times of appearance, some discrepancies occurred, yet the times of disappearance, which can be determined with more precision, gave results which agreed with each other within a few tenths of a second. It is easy to perceive that much uncertainty may exist respecting the precise moment of the first appearance of a meteor, it being scarcely probable that the attention of the observers at different places would be at the same moment directed exactly to the same point in the heavens.

The impossibility, at present, of anticipating the nights in which the phenomena of shooting stars may be observed, and the great interest which all such meteorological phenomena have, make a meteor from uncertainty, the chief obstacle to the general employment of this method of finding the differences of longitude between places. A few observations of such a nature have been made, but a little on which much dependence can be placed; and a single observation appears to be liable to a risk of error amounting to several seconds of time in a computed difference of longitude.

(See Abstracts of the papers, by Messrs. Galloway and Drach, read before the Royal Astronomical Society, in the Monthly Notices for January, 1841, and December, 1841.)

SIBALIA (in honour of Robert Siddons, formerly Professor of Physick at Edinburg). A genus of plants belonging to the natural order Rosacea. It has a concea 10-petaled calyx, the inner segments necessary. It has 5 yellow or white petals, 5 sepals, and a lateral style. The fruit is in the form of a long axis, like a fruit, with a few seeds. It differs from the genus S. piperiflora in having a head of flowers, with three leaves at the apex, rather pilose, the flowers corolla-like, petals yellow, small, shorter than the calyx. It is found on dry mountains in Scotland, in Europe, Siberia, and North America.

S. piperiflora is a native of Cappadocia. It has trifidile leaves, the leaflets beset with aconite pili on both surfaces, the flowers con-

SIDDONS. MRS. SARAH, was born at Brecon, in South Wales, July 5, 1796. She was the eldest child of Mr. Roger Kemble and Sarah his wife (whose maiden name was Ward), and, while a mere infant, made her first appearance on the stage on the occasion of her father's benefit. The audience expressed their disapprobation of what they considered too premature an exhibition; but Mrs. Kemble boldly led the infant child forward, and displayed her as the well-known fable of 'The Boy and the Frog.' From that period Miss Kemble continued to perform regularly in her father's company till she attained her fifteenth year; and, at the age of thirteen, she was engaged at the Theatre, and placed under the protection of Mrs. Greenhead, of Guy's Cliff, Warwickshire, in the capacity of reader and companion. At the age of eighteen the affection of the young couple being unhindred by separation, Mr. and Mrs. Kemble consented to their union. They were married at Trinity Church, Coventry, November 26, 1773, and the young bride returned to the provincial stage at Cheltenham in company with her husband: 'It was a happy,' remarks Mr. Boswell, in his Life of Mrs. Siddons, 'in the present...'
Lady Randolph, Mrs. Crawford, at Covent Garden, and Mrs. Siddons, at Drury Lane, and added another leaf to the laurels of the latter. In 1784 a cabal was made against her, upon a most unfounded charge of illiberality towards two brothers performers, and in her absence she declined to sit upon the opening of Drury Lane, on the 5th of October, having been assailed by hooting and hissing on her appearance as Mrs. Beverley. On the 2nd of February, 1784, Dr. Siddons first performed Lady Macbeth, in 1789, Siddons opened Holland's new Drury Lane Theatre by the performance of Lady Macbeth, on which occasion her son Charles made his first appearance in the character of Macduff; and, in 1800, she again, as Lady Macbeth, was adored at the opening of the present Covent Garden Theatre, September 18th. The famous or rather infamous O. P. Row ensuing, seven months elapsed before she made her second appearance that season, repeating Lady Macbeth on the 24th of April, 1810. "Such an interval," says Mr. Bouden, "spoke loudly for the taste of a London audience." Two years afterwards, on the 29th of June, 1812, Mrs. Siddons herself, bare of the stage she had so long adorned by her genius and elevated by her private conduct, in the same celebrated character of Lady Macbeth, after which she spoke a farewell address, written by her nephew, Mr. H. B. Bordon, however, during the next season she was induced to revisit the scenes and revive the recollections of her former glories; she performed on the 25th of May for the Covent Garden Theatrical Fund; on the 16th of June for the benefit of Sir Charles Kemble's benefit, and the 29th of same month at Drury Lane for the fund of that theatre. In November, 1816, she acted for ten nights at Edinburgh for the benefit of the widow and family of her son Henry; again at Covent Garden in 1815, for benefits and charities, and at the request of the Princess Charlotte of Wales, who was, however, unfortunately prevented by illness from witnessing the performance. In 1817 she performed one of the last (June 5) for Mr. C. Kemble benefit, and made positively her last appearance upon any stage at Covent Garden, June 9, 1816, for the benefit of Mr. and Mrs. Charles Kemble, in the character of Lady Randolph. For two seasons after her public farewell in 1812, Mrs. Siddons gave occasional readings alternately from Shakspere and Milton at the Argyle Rooms, having been led to do so in the first instance by the kind desire of serving the widow of Mr. Cherry, author of "The Soldier's Daughter." She was also honored by a command to read to Queen Charlotte and the Royal family at Frogmore, and an invitation from the Universities of Oxford and Cambridge. "Whether this great actress regretted the stated calls to exertion, says Mr. Bouden; but she was not cowed; and the however there can be little doubt, from the following remarks, which she one day made, to an old and attached friend, an old friend, toasting her, "and if there is not love, I cannot speak. We were all in the month of the evening she had been accustomed to repair to the theatre to dress for the performance. At this time, she observed, every body in London is in the business of thinking of me. The tone in which this was spoken, and the sight which accompanied it, sufficiently indicated the feeling with which she contrasted her public and private life, although still the queen of every circle she condescended to enter. She died on the 8th of June 1831, about nine in the morning, at her residence in Upper Baker Street, in the 76th year of her age, and the prophecy of Henderson has not yet been falsified. The talents of this great woman, remarks one of her biographers, "are said to have been slowly developed, and the growing claims of her family seemed to be the only unrestrained calls upon her genius. At length fully kindled, it burst suddenly forth into an exhalation that had never been witnessed, and railed in its charm the spell of the greatest enchantress Garrick in all but his universality." Mrs. Siddons lost her second daughter, Maria, in 1793; her husband in 1802; her eldest daughter, Sarah, in 1803; and her son, Henry, in 1815; a third daughter not long after. Cecil, the last child, and George survived her. Amongst the most celebrated portraits of this unrivalled actress are a full-length in the character of Isabella holding her son Henry by the hand, painted by Hamilton in 1762; another, in the character of the tragic muse, painted by Reynolds, painted in 1784, and now in the collection of the Earl of Westminister; a third, reading "Paradise Lost," Mrs. Siddons' personal figure; a fourth, as a Lady Macbeth, by Hargreave, which graced her table with a well-known picture of the trial scene from "Henry VIII." executed for Mr. Thomas Welsh; and shortly before her death she sat to the late H. P. Briggs, Esq., R.A., whose interesting portrait of her (a three-quarter length) was exhibited at Somerset House, but has not been engraved.

Memoirs of Mrs. Siddons by Mr. Bouden, were published in 1827, 2 vols. 8vo.; and after her decease, Mr. Thomas Campbell became her biographer. His work, published in 1834, is also in two volumes, and partly compiled from the M.S. notes of Mrs. Siddons herself. There is also a memoir of her in Galv's "Lives of the Players," which, the writer informs us, in a postscript, he had but just completed when he received the news of her having that morning expired.

SIDMOUTH, a town on the Devonshire coast, in the east division of Budleigh Hundred, 134 miles E.S.E. from Exeter. The area of the parish is 1790 acres; the population at the successive enumerations was as follows: 1801, 1252; 1811, 1688; 1821, 2747; 1831, 3126; and 1841, 3306. The number of houses at the last enumeration was 715; namely, 634 inhabited, 77 uninhabited, and 4 building. The memorial of Mrs. Siddons by Mr. Bouden, was erected at the opening of the present Covent Garden Theatre, September 18th. In 1688; 1727, 4; 1794, 100; 1816, 73; 1827, 360; 1841, 2747; 1871, 374; and 1881, 4811. There were in the parish, in the year 1833, an infant-school, with 95 children; namely, 22 boys and 73 girls, supported by voluntary contributions; four day-schools, with 117 children, namely 29 boys and 88 girls (one of these schools, with 40 scholars, being partly supported by voluntary contributions); a boarding-school, with 12 girls; and a parish-school, with 137 children, namely, 100 boys and 37 girls, giving 300 children (namely 302 boys and 158 girls) or rather more than one in nine of the population, according to the enumeration of 1831, under daily instruction. The parish school was also a Sunday-school, attended by 148 children, namely, 88 boys and 60 girls, and there were two other Sunday-schools, with 145 children, namely 45 boys and 100 girls, giving a total of 298 Sunday-schoolers, namely 133 boys and 165 girls, or less than one in ten of the population. (Parliamantary Papers; Ordnance Maps; Lewis's Topographical Dictionary; Lysons's Magna Britannia.)

SIDMOUTH, HENRY ADDINGTON, VISCOUNT.

The father of Lord Sidmouth was Dr. Anthony Addington, a physician, who, after practising for some time with considerable distinction in London, was induced by the state of his health to retire from the metropolis, and to settle in Reading, where he died in 1750. Dr. Addington married in 1746 Mary, daughter of the Rev. Harland John Eliley, of Borrowingtoft, in the county of Lincoln, who died in the 30th of May, 1757, was their eldest son. Mrs. Addington died in 1778. In the beginning of that same year Dr. Addington obtained much notoriety by a strange attempt in which he, his wife, and their two daughters, the first and second attendant of the Earl of Burlington, to bring about a political
S I D

alliance between that nobleman and the Earl of Chatham, whom Addington had been in the habit of visiting in his professional capacity. The negotiation, which of course came to nothing, appears to have originated solely with the two physicians—who afterwards quarrelled upon the subject—and amounted to nothing more than a series of expressions and recriminations—and to have been carried on for the greater part without the knowledge of the two noble persons who were principally concerned. Lord Chatham was at the time on his deathbed.

Meanwhile Addington's son Henry, after having commenced his classical education at Winchester School, had been entered at Brasenose College, Oxford, in January, 1779, to the office of a resident of the Lord of Lincolns Inn, and in 1784 obtained the Bachelor's Prize for an English essay. On leaving the university he entered himself a student of Lincoln's Inn, and was called to the bar on the 11th of May, 1784.

Events, however, had by this time taken a course which had the effect of withdrawing him from the further pursuit of his profession upon which he had thus entered. His father's connection with the family of Lord Chatham had led to an intimacy while they were yet boys between him and the younger William Pitt, who was his junior by about three years, but had been in parliament since 1780, and was already, with Pitt, regarded as a promising name in the post of first minister of the crown. Addington is said to have been previously fond of attending the debates in the House of Commons; his brother-in-law, James Sutton, Esq., of New Park, had expressed to him, on Mr. Pitt's suggestion, that he stood for and succeeded in getting himself returned for that borough at the general election which proceeded the opening of the new parliament on the 18th of May, 1784.

The long political career upon which he now entered was not marked by many events in which he bore a prominent part, and its general course may be briefly traced. So long as he was only a young member of the House of Commons, in which he retained his seat for Devizes until he became a peer—he was, as might be expected, one of Mr. Pitt's steadfast supporters. Accordingly, when the office of Speaker became vacant in May, 1780, by the resignation of Mr. (afterwards Lord) Grenville to be secretary of state, Addington, although so comparatively young a member, was put forward as the ministerial candidate, and was elected by a large majority. He filled the chair, with considerable credit if not with any remarkable distinction, till on the retirement of Pitt, in March, 1801, he was induced to undertake the formation and chiefship of a new ministry, with the offices of chancellor of the exchequer and president of the board of trade, which time had been held by his predecessor. He differed, therefore, it now appeared, from Pitt upon the great question of Catholic Emancipation, upon which that minister had gone out; but there is no evidence that any conflict of principle or views had by this time considerably diverged. Addington had come to be considered as the leader or head of the class of persons especially styled the King's Friends; and it was thought to have been at the express request of his majesty that he now assumed office.

The most memorable event of Mr. Addington's short administration was the Peace of Amiens, which proved still shorter than his author's tenure of power. Soon after the renewal of the war in the beginning of 1803, Pitt, who had hitherto supported his old friend, began to intimate an apprehension that he was scarcely equal to the crisis, and then openly joined Fox and the opposition. The occasion was that Addington resigned, and Pitt was restored to power in May of the following year.

The displaced minister however made no attempt to form a party against his successor. He would probably indeed have admitted as readily as any one else that Mr. Pitt was the preferable person of the two to be at the head of affairs at such a moment, now that he was willing to accept the post upon the condition—namely, the abandonment of the question of Catholic emancipation—which he had formerly rejected, but which the king, and, it must be added, the great majority of the country and both houses of parliament, regarded as indispensable to the security of the nation. In May, 1804, was a concession on his part of a great point and a great principle, and a decided victory obtained by George III. and his friend Addington. The new government was from the first considerably supported by its public opinion, and in 1805, after he had taken office as president of the council, being at the same time made a peer by the title of Viscount Sidmouth. It is said that he accepted this elevation, which removed him from the House of Commons, with much reluctance.

The writer (probably a near relative) of an extended and elaborate memoir of Lord Sidmouth, in the 'Gentleman's Magazine' for April, 1844, ascribes full credit to every other event of any importance in his lordship's career, merely informs us, without a word of explanation, that he resigned the presidency of the council in July of the same year in which he accepted that office. The causes are thus stated in the 'Annual Register,' in the relation of the proceedings, so distressing to Pitt, which were taken against Lord Melville:—"During the whole of these proceedings the new chancellor [Addington] has been so pertinacious in adhering to the minister, and took an eager and an active part in bringing Lord Melville to the bar of public justice: conduct which must have been considered as a deflection from the government of which they formed a part, and, as such, must have been deeply resented by the minister. It was also rumoured that other causes of dissatisfaction and disagreement existed between Mr. Pitt and Lord Sidmouth at this period: that the former was jealous of the influence which the latter maintained in a certain quarter, which had lately been manifested in the conferring of high ecclesiastical dignities and that, instead of gaining a useful ally, Mr. Pitt had only exposed himself to the machinations of the individual—that the reports were founded in truth it is not our province to decide; but certain it is that on the 10th day of July the Viscount Sidmouth and the Earl of Buckinghamshire resigned their respective offices.

When Mr. Fox and Lord Grenville succeeded to power in February, 1806, after the death of Pitt, Lord Sidmouth was made lord privy seal; and when the ministry was re-constructed in October, he was replaced in his former post of president of the council, which he held till the breaking up of Lord Grenville's government in March following. After this he remained out of office for about five years. Then, in April, 1812, in the last moment of the Pitt administration, he was appointed president of the council for the third time. In June of the same year, when Lord Liverpool assumed the premiership after the assassination of Mr. Perceval, Lord Sidmouth became secretary of state for the third time. This office, which for the first time gave him much of a real share in the business of government, he continued to hold for the next ten years. His conduct on several occasions, as, for instance, on that of the great meeting for reform held in Manchester in August, 1819, exposed him to a good deal of popular outcry and obloquy; but he was never charged with being deficient in decision and fearlessness, and he at all times retained the confidence of the nation. He continued to attend frequently in the House of Lords, though he seldom spoke. He had at no time, indeed, been accustomed to come forward much in debate. He sur- vived till the 10th of August; dying at his residence, the White Lodge, in Richmond Park, of which he was deputy ranger. Lord Sidmouth was twice married; first in 1781, to Ursula Mary, daughter of Leonard Haunmond, of Cheven, in the county of Surrey, Esq., who died in 1811, after bringing him four sons and four daughters; secondly, in 1825, to the honourable Marianne, widow of Thomas Townsend, of Bonington Park, in the county of Warwick, Esq., and only daughter of Lord Stowell, who died also before him in 1842.

(Gentleman's Magazine, for April, 1844.)

SIEGEN, LUDWIG VON, the inventor of mezzotint engraving, was born in Utrecht in 1606, of an ancient and noble family of Westphalia. His mother was a native of Holland, but of Spanish origin; her name was Anna Perer, and Johann von Siegen, the father of Ludwig, was her second husband. Ludwig was the third son of his parents. In 1616 Ludwig's mother died, and his father Johann entered in the following year into the service of Prince Maurice of Hesse and removed to Cassel, where he was placed at the head of the Latin College in the princely residence. In 1634 he became professor of history, and in 1639 of law at the university; and in 1642 he also became professor of rhetoric. He was a very learned man and a capable jurist, and contributed to the development of the science of law in the territory of Hesse. In 1644 he was appointed professor of history at the University of Halle, and in 1649 he was made a member of the Academy of Sciences. He was a very active writer, and his works were widely read. He died in 1681.
ment in the year following, and his successor William V. surrendered the college altogether. Johann von Siegen retired to Juliers and afterwards to Kampen in Holland, where he died in 1655.

It is commonly believed that the death of Ludwig von Siegen from the time that he left the college of Casel in 1626 until 1637, except that he was in France and Holland, and it is probable that he was doing military service in this time. In 1637 after the death of the Landgrave of Hesse, he was appointed page to the young prince William VI., by his mother the regent Amelie Elisabeth of Hanau, and in two years afterwards he received the title of Kammerjunker, and served in that capacity until 1641. It was in the years between 1637 and 1641, that Siegen discovered his new method of engraving, but he removed in 1641, or in the beginning of 1642, to Amsterdam, without importing his secret in Germany. On the 18th of August, 1642 he sent a letter from Amsterdam to the Landgrave, enclosing some proofs of a portrait of his mother Amelie Elisabeth, and the plate of these prints is the first mezzotinto engraving. Siegen speaks of his portrait in the letter referred to as executed in a new and astonishing manner, invented by him: and to further observe, that no engraver will be able to devise the manner in which it was executed. This letter still exists among the archives in the library of Casel, and a specimen of this engraving is given in La Plaume's Histoire de la Gravure en Manière Noire, (History of Mezzotinto Engraving).

This earliest mezzotinto engraving, though as the above letter shows it was executed in 1642, was not published until 1648, when it appeared with the date altered to that year, together with a portrait of Elizabeth of Hungary; and the prints drawn off by Siegen himself, not already disposed of, were sold with a pen to the same date; specimens of all three still exist. The incision of the original print was as follows:

Comitissa Hannoverianus, etc.
him on the highest pinnacle of political popularity. The first was entitled "Essai sur les Privilèges," the second and the most remarkable, "Qu'est-ce que le Tiers Etat?" in which he asserts that the "Tiers Etat" is the nation itself; he then proceeded to show, by the most powerful and the most persuasive influence on the government of France, and he demands for it a political recognition. The title of the third pamphlet was "Moyens d'Exécution dont les Réprésentants de la France pourront faire usage pour obtenir l'abolition de l'illimité des nobles;" and it was thought soon became realities through his active influence. On the convocation of the States-General Siewes was elected deputy for Paris. An opportunity for carrying his scheme into effect was now afforded by the second三级 of the representatives of the people to constitute themselves into an independent body, called the National Assembly (June 16, 1789). He it was likewise who proposed the oath which was taken by all the members at the "Jeu de Paume" (Bailey, P. C.) never to separate themselves, but to assemble whenever circumstances required until the perfect establishment of the constitution. This sudden and vigorous measure, which must have proved the immediate signal of civil war had not the power of the other orders of the state been already paralysed. He was vehemently opposed by Mirabeau (Bailey, P. C.) at the head of the more moderate of the republican party; it was however carried by a very large majority. So great was the popularity of Siewes that, on presenting himself before the Assembly, he was hailed and reiterates against the members present, who rose up to receive him. On the meeting of the 23rd of June, when the king declared the resolutions of the Assembly to be null and void, and ordered the members to disband, he pointed out that they were still the same body to-day that they had been the day before, and tidied them proceed in their deliberations. They did deliberate," says a writer in the "Foreign Quaterly Review," "and the resolution was the result." Siewes was also the framer of the decree which was passed on the 30th of October, by which the ancient provinces were abolished, and France was divided into departments all governed by the same law. (France, P. C.)

He continued to take a prominent part in the deliberations of the National Assembly until the publication of those decrees which he considered of too levelling a nature, and which alarmed him as to the ultimate result of the innovations which he had himself been too eager to introduce. Acquainted with command, he was unable to endure contradiction, and when he found that the measures which he opposed were carried in spite of his influence, he betook himself to a sullen silence from which even the persuasions of his eloquent colleague, Mirabeau, were unable to rouse him. The most important of these occasions occurred a few days after the taking of the Bastille. To this he was favourable; but he considered that they should be purchased by the landed proprietors, and an indemnity for their loss made to the tithe-holders. To this indemnity, however, the Assembly adhered, and a few days later the Assembly determined to disband and to dismiss the National Guards. He behaved on this critical occasion with his usual coolness, and, as he charged, "the English who live in this country never return, Mr. Poule should return, inform him that I am not at home." In 1796 Siewes was named by the Council of Ancients one of the five directors, but he declined the proposed honour, and Carnot was appointed in his stead.

In 1798 Siewes was sent on a mission from the French Government to the court of Berlin, in which, though he failed in his attempt to bring France and Germany to a reconciliation in securing its neutrality. On his return to Paris the following year he was named member of the Directory, a nomination which showed the disposition of the councils, as he had openly expressed his disaffection with the directory government. Placing himself at the head of a conspiracy which had been formed against three of his colleagues, who were known for their republican sentiments, he procured their forced resignation, and a new Directory was formed in which the majority was favourable to his views. Another important measure which he effected through the Instrumentality of the Minister of Police, Fouche, was the closing of the Jacobin Club, a body which the author of "La Fuite" held "in the very centre of those exactions of the Revolution. These measures, as they destroyed the popularity of the author of the Tiers Etat, and exposed him to the vengeance of republican fury, made him anxious to secure political and temporary safety, and to turn his talent and energy to take upon himself the sole direction of the affairs of state. 'We must have no more dealings with declaimers,' said he, 'we want a head and a sword.'"

In 1798 he was appointed one of the six delegates to the newly organized Military chiefs that were to be the executors of the laws of the highest renown; but they appeared to Siewes to fail in the necessary requisites for a civil ruler. Jouber, in whom he hoped to find them, had recently fallen at Novi. Masseau and Desaunay, the Jacobin generals, and Couthon and Collot were too well known for their democratic sentiments. The arrival of Bonaparte from Egypt (Bonnare, P. C.; Kléber, P. C.) determined the difficulty; the penetration of the }
of Sieyes discovered in him a fit associate for his designs. They were favoured by the enthusiastic reception which Bonaparte met with from all ranks and parties on his arrival, by the sympathy of some of his old associates, and by the active  operation of many of the French generals and the most influential members of the legislature. The talents and influence of Sieyes were appreciated by Bonaparte, while the speculative and visionary character of his theories was probably appreciated the English but as children in the art of framing a constitution, and that he considered himself capable of giving a much better one to France. (Dumont, *Souvenirs de Mirabeau*, p. 60.)

Sieyes was probably more successful as a political philosopher than on one occasion he remarked that the art of government was a science which he considered he had brought to perfection. This disposition may have been the cause of many of his crude measures, the necessity of co-operation with the state, and the statesman perceived that a salutary change could not take place without the strong support of the People. The Revolution of the 18th Brumaire (9th Nov., 1799) was the result of this co-operation, and Napoleon, Sieyes, and Roger Ducos were the first consuls named, and two commissions of twenty-five members each were appointed from each Council of State to assist the consuls in the formation of a new constitution. In the formation of this constitution, however, Sieyes and Bonaparte soon disagreed; Sieyes was allowed to form a constitution according to his political speculations, and he made it consist of a Senate without the power of debate, and a Tribunate which was to discuss with the Council of State the legislative measures proposed. But to his disgust, he found that nothing, respecting the Tribunate, which he thought should be vested in a Grand Elector, whose sole power was to consist in the nomination of two consuls who were to exercise all the powers of government, Bonaparte offered a vigorous and determined opposition. Discontented with the overthrow of his political theory, and discovering with characteristic penetration that he had found his master, he refused to act a subordinate part in the new constitution, which was proclaimed on the 5th December, 1799. At this period he may be said to have terminated his public career. His services however were richly rewarded with 600,000 francs and the estate of Crome, which was afterwards exchanged for a magnificent hotel in Paris, and the valuable lands of Falsudrie in the park of Versailles. "Thus the democratic fervour of the author of the pamphlet "What is the Tiers Etat?" sunk into the interested apathy of the proprietor of fifty thousand pounds" (Allan). This writer quotes also from the "Memoirs of Gohier" an incident characteristic of the extreme cupidity of Sieyes, to use no severer term (History of Europe, vol. iii., p. 785), but it must be remembered that Gohier was the President of the Directory on the 18th Brumaire, that he was strongly opposed to Sieyes in political opinions, and that he evinces throughout his Memoirs much personal hostility towards him.

The 1st consul and the empire, Sieyes studiously avoided all participation in power. He declined the offer of the presidency of the Senate, and contented himself with accepting the title of Count. Napoleon borrowed largely from his works, and had the talent to translate into acts many of his political ideas formed the basis of the legislative measures which he introduced. At the Restoration he was exiled, and only returned to France after the Revolution of 1830, thirty years afterwards. He died at Paris, in tranquill obliquity, on the 20th June, 1836.

The character of Sieyes has been graphically depicted by Dumont (Dumont, P. C.) in his valuable and interesting Memoirs. "His manner, he says, was neither frank nor engaging; he was a man with whom it was difficult to become intimate, and who was wont to express his opinion without desiring to enter into any discussion upon it. His writings had given him the reputation of an established president; he that was put upon the oracle of the Tiers Etat, and the most formidable enemy of privileges. He was easily excited to a display of ill humour, and appeared to hold in extreme contempt the existing régime of society, and the institution of liberty necessarily a liking for the English nation, and the subject being familiar to me, I introduced it to him, but I very soon changed the subject. Of the English constitution was in his eyes a mere piece of charlatanry to impose upon the people: he seemed to pity my ignorance as I described the various modifications that system had undergone, the immense strides it had made. He was of opinion, that towards each other by the three orders of the state, the hidden checks which they opposed to each other's movements, and the disguised but real dependence which existed between them. The influence of the Pope and of the King tended to impress them, the opposition a mere court trick ("manque d'antichambre")."

The only thing he approved of among the English was trial by jury, which, however, he but little understood, and, in common with most Frenchmen, he had formed wrong notions concerning the whole system of parliamentary government. He thought the English but as children in the art of framing a constitution, and that he considered himself capable of giving a much better one to France. (Dumont, *Souvenirs de Mirabeau*, p. 60.)

Sieyes, no doubt, was a man of great ability, a warm and ardent supporter of the revolutionary principles, and a most formidable exponent of them; but he was also a man of an extraordinary independence of spirit, and in all his political speculations a child of the Revolution; that is, a man who lived and spoke only according to the ideas of the time in which he lived. Situation and opinions of course, are, with all men, the necessary consequence of the way in which they have been brought up. There is also an admirable sketch of his character in Mignet, *Hist. de la Révolution*, c. ii.

His speeches are printed in the "Moniteur" of the time.

SILVER, GERMAN. [Gilding, P. C., p. 504.]

SILVINGUM, a genus of composite plants belonging to the
tribe Cynareae and the section Silvenses. It has an imbricated
involucre, which forms a loose, spreading spinous receptacle. The
fruit is scaly. The fruit compressed, its terminal aroela surrounded by a papillose ring.

S. maximus, is the only species. It has a stem from 3 to 4 feet high, and is covered with the
involution of the involucral scale closely adpressed below. The florets are purplish, with a brown tube. This plant is found in waste places in
Great Britain.

(Babington, Manual of British Botany.)

SINDE or SCIINDA is that part of Hindostan which exten-
s the province of North and is bounded on the north by
the junction of the Indus with the Jamna. Its
area is
76,000 square miles, of which more than
10,000 is occupied by water.

The Indus. Sind is indebted for its fertility to the inundations of the Indus. As far as these inundations extend, the country yields abundant crops; where they cease, and no means of irrigation are used, the country is a desert. These inundations however are not derived from the same cause as those of the Ganges. The inundations in Bengal are almost entirely the effect of the periodical rains during the south-ea
windy season, while the Indus, in addition to the waters receive from the melting of the snow in the Himalaya mountains, is comparatively small. The waters of the Indus are very little increased by rains, as the rains which fall in its basin are principally used in supplying the waters of the rivers of the Punjab, the addition of which makes the waters receive not from the snow, but from the waters of the
Indus.

As in these parts the difference of the snow-line in summer and winter amounts to 5000 feet, an immense volume of snow must annually be dissolved, and the water thus produced must greatly raise the level of the river. Even in the lower course of the Indus the difference of the level between the highest and lowest points amounts to 12 feet. As the banks of the river in very few places attain such height, the waters spread over the adjacent levels and fertilize the soil.

Artificial means are employed to increase these advantages, especially canals and dams. The canals serve two ends. The river is carried to high grounds by means of the inundations; and where they do not naturally disperse over the adjacent country, they are conveyed there by means of the feminist wheel. These canals are only full during the rainy season, the waters of the Indus being dry in winter. The dam are made across the bed of the river, and are of
two different descriptions. Many of them have an opening in the middle, by which all the water escapes when the river is low, but which is covered and stopped up when the volume of water is great. The water thus impeded accumulates above the dam so as to cover a large tract of country. In those parts of the river however which have risen during the rainy season the water receives only a small amount, the water, the dam have no opening. The whole volume is thus driven back and spreads over the district above the dam, and the bed of the river below it would remain dry if the water which is carried by canals over the country did not find by these canals a way to the bed of the river below the dam. These dams are called bunds.

The river begins to rise in April. Early in May the swell of the waters begins to point out the necessity of deepening and cleaning out the various canals. Towards the middle of June there is sufficient water for sowing the crops, which ripen and are cut down in October. At the end of September the waters begin to recede, and in October the waters of the Indus are at low

A few miles below the point where the Indus is joined by the Jamna, the river enters Sind. About 60 miles lower down, and only about 24 miles above Buhur, it begins to divide into branches. About 10 miles below Buhur it branches off on the eastern side, which is called the Eastern Narra. It appears that this arm formerly received a great, if not the greatest, part of the waters brought down, but that the river changed its course more to the west. After this event had taken place, a hand was erected across the Narra, near the ancient town of Arore, which is still called the Arore Bund. Thus the Narra was deprived of the annual supply of water, except when the water in the Indus rose to an unusual height, as in 1831. Its bed would generally be dry, if it did not receive a small supply of water from a remarkable depression, which extends parallel to the Garha and Chhina rivers from the vicinity of the town of Arore, and in which running water is found during four or five months of the year. This depression, being considerably lower than the flood-level of the above-named rivers, receives a good deal of water from them through canals and becomes a small stream, and which sends two branches to the Poornam under the name of Goomeer. After this accession of water the Poornam has a well-defined channel from 12 to 20 feet deep and from 600-
The artesian well water is gaining importance in some of the towns of the state. The water table is shallow in the plains and mountains, and the artesian well water is of high quality. The water is used for irrigation, drinking, and industrial purposes. The artesian wells are dug by the villagers and are maintained by them. The water is stored in tanks and used as required. The artesian water is free from contamination and is considered to be healthier than the surface water. The artesian wells are an important source of water in the desert areas of the state.
parts of the river which run east and west, that the water may be thrown south into the interior. Some of these canals are of great extent. One of them, called the Meerwah, conducts by a southerly course the waters of the Indus from the north-western monsoon, which is, often over 150 miles in length, where they are lost in sands or dispersed over the fields. The soil of this tract is alluvial, with the exception of a small rocky district which crosses the Indus at Bukhar, and extends on the west of the river. The banks of all these canals are fringed with a broad agricultural hand, on which numerous large villages are built, many of which contain 500 houses. Besides fertilizing the land, these canals afford the means of hydrography, and are taken as a work of art. In the fair season, when dry, they become the beaten path of the people and are excellent cart-roads. Beyond the reach of the water of the canals, the country is very little cultivated. Though the components of the soil do not differ from those of the cultivated tracts, it is hard and sandy. Dry and cracked from the heat of the sun, the loosened sand is raised by the prevailing westerly winds into little hillocks from between thirty feet high, which gradually assume the appearance of a desert running imperceptibly into the Thurr. Only at a few places grain is cultivated, as its growth depends on rain, which is very uncertain in these parts of Sind. The lower parts of the non-cultivated ground are generally overrun with tamarisk jungle.

The country south of a line drawn from Hyderabad to Qandahar, and which runs through the channel of the Indus, generally resembles the region just noticed. In its most northern corner, where the Indus and its Falaloo branch run nearly parallel, is a low ridge of rocks which extends for some distance, and on which are seated small and isolated hills of limestone, of moderate elevation. Except these hills the country is flat and well cultivated in the vicinity of the numerous canals, which bring to the interior the waters of the Sutu and Pigharoe branches. Between the Pigharoe and the Poornua a considerable extent of country is covered by a salt-marsh. The country near the last-mentioned branch of the Indus is little cultivated, except in the vicinity of the Goomar river. Towards the south-west is a large desert, resembling the Rann. There are hardly any plants met with, except a saline plant called dorse, which forms the principal food of the camels in this uninhabited country. The soil is of such a description as not to absorb water, which therefore remains upon the level surface until it is carried off by evaporation. Indifferent water may be obtained in many parts of this desert by digging wells to the depth of eighteen feet. This sterile tract extends twenty miles from the sea and the Keree mouth of the Indus to the north-eastern part of the peninsula of Gujerat, a distance of about 200 miles; in breadth it is about 35, but there are various belts and ramifications, by the addition of which its area is increased to 7000 square miles. It is a perfectly level country, bathed in the sun, and not even the most stunted vegetable. The soil is a mixture of mud, sand, and clay, and is covered with a thick incrustation of salt in the dry season, and during the south-western monsoon, and banks of all the canals, and the common level of the sea, it is lower than the adjacent country. The southern banks are in many places very fertile, often sandy, and in some parts alluvial. On these waters of the Goomar, and on the valley of the Indus, there are tanks of rain-water, within 200 yards from the Rann itself, retain their sweetness for many months. There are some islands in it where fresh water occurs, but it is scarce. By some the Rann has been called a marsh, but it has none of its characteristics: it is not covered or saturated with water, but at certain periods: it has neither weeds nor grass in its bed, which, instead of being alimy, is hard, dry, and sandy, and of such a consistence as never to become clayey; nor is it otherwise funny or swampy. That singular phenomenon called mirage nowhere produces such delusions as in this tract; the smallest shrub at a distance assumes the appearance of a forest.

The climate of Sind differs greatly from that of other parts of Hindustan. Though the south-west monsoon commences in June, its breezes are not strong until the end of August, and the cold season is therefore much prolonged. The heat of the winter becomes intense in the middle of March, and it continues generally without intermission till the end of August or the middle of September. The storms of thunder attended by rain which occasionally occur in June or July afford a brief respite from the heat. A curious phenomenon is observed in this country on the setting in of one of these storms, it being always preceded for two or three days by a close atmosphere loaded with a fine description of which produces a heavy mist or thick fog. But immediately previous to the bursting of a storm the air is literally darkened by immense volumes of sand driven in black masses before the wind, and obscuring the whole surface of the country. These sand-storms, which bear a great resemblance to the pampers of Buenos Ayres, appear to be the natural effects of the desert countries surrounding Upper Sind, over which no violent wind can pass without raising clouds of the shifting sands which cover their surface. The heat of Upper Sind from the middle of April to the end of July is said to exceed that of any part of India, and the thermometer rises sometimes to 120° in the shade. The hot southern breezes are at times so strong till midnight, but the mornings are generally cool. During the hot season the whole country, except the green forests of balsoo which skirt the banks of the Indus, presents a most arid appearance. With it only rains, which by the general rise of the river laying much of the country on each bank under water. In September and October, when it leaves the country, the water quickly dries up, and leaves a dry and cracked soil, except in those tracts which have been cultivated.

During the cold season, from October to the end of February, the climate of Upper Sind is pleasant and salubrious. Frost is occasioned by the occasional return of the cold air which assumes the appearance of winter in the northern climates. The setting in of the cold and violent northern winds of November stops all vegetation except a few stunted
tamarisk and babool bushes. Frost and blighting dew follow, and tend also to destroy a great portion of what otherwise would have been germs of vegetable life, which, if they chance to escape, rise only to be annihilated by the heats of April. Some have supposed that Sind comprehends the whole of this effect, not only to the European, but the native constitution, and during certain periods of the year exposure to it is as much as possibly avoided by the people of the country. It is only lately become accessible to Europeans, we have not yet received any series of meteorological observations extending over a whole year. But we have observations made at Kurachee on the sea-shore, and at Sukkur in the Indus, for five months in 1844, and the result of them is very interesting.

**KURACHEE.**

Average Heat.

At noon. At 3 p.m. At 9 p.m.
May, 82° 88° 94°
June, 87 93 99
July, 83 89 99
August, 84 91 96
Sept., 77 81 83

From this table we learn that the climate of Sind is really hotter than in those parts of Hindostan which lie in the vicinity of the equator. The difference between the temperature of Kurachee and Sukkur ought also to be noticed. In the last-mentioned place the thermometer rises at noon to nearly 94°, but is a few degrees higher, though Kurachee lies nearly four degrees nearer the equator. This difference is to be ascribed to the desert countries by which Sukkur is surrounded. At this place the heat of 9 o'clock in the afternoon during the hottest part of the day only reaches 84°, whereas at Kurachee it is 94°. This difference is so intense that at noon. This is solely to be ascribed to the hot southerly winds, which invariably continue to blow with considerable force till midnight.

**Production.**—Sind is rich in productions. Though its botanical wealth is not great, the agricultural productions are numerous; all the grains and pulse common to India are grown. Rice is the staple in the delta and in the country between the Western Narra and the Indus, but in the other parts wheat and jowar (large maize) are most extensively cultivated; next to these Holcus sanguineus and Phaeaceus mango. Barley is grown in some districts; other articles are, Phaeaceus maximus, Erynum levis, Panicum italicum, and Cicer arietinum. Indigo is largely grown in the north-eastern districts, but it is inferior to that of Bengal. Oplum is cultivated near Shikarpore, and in some other districts.

The sugar-cane is pretty generally grown throughout the whole of the province, but its production is inferior to that of Northern Hindostan and the Punjab. Cotton is cultivated everywhere, but the quality in the north is superior. The cotton cloth of the country is grown in the vicinity of Khyporo. Hemp, cucumbers, water melons and musk melons, are extensively cultivated, as are also cucumis and anise. There is a great variety of greens grown in the country, and among the boiled vegetables, which grow spontaneously, are purslain and a species of amaranthus. The gardens produce carrots, turnips, radishes, onions, and several kinds of pumpkins, the egg-plant, three kinds of beans, peas, the *Admersonia charantia*, dill, and mustard.

The root of the lown, which covers a great portion of the Lake of Munchar, is eaten. Sesamin, garum, garci- cus, and turmeric abound, and the last is used as a dye. Among the fruits are the date, mango, pomegranate, apple, grape, lime, citron, fig, apricot, pista, and coconuts, several kinds of wild plum, and the tamarind, but most of these fruits are indifferent, and much inferior to those of Cabool, about Shikarpore and Bokhna. The dates are so plentiful as to constitute the principal food of the lower classes, but they are inferior in size and flavour to the Arabian and Egyptian dates, though superior to those of Northern India.

The tamarind is the most abundant production of the cultivated parts, and almost as useful to the inhabitants as the bamboo to the native of India. The flowers form an article of export to Persia and the Punjab under the name of amla. When dried and preserved in water, they yield a red fluid in which cottons are steeped to prepare them for dye. The wood supplies the inhabitants almost exclusively with fuel, and it is in the construction of houses, boats, and agricultural implements. The boughs are used for fences and cattle-sheds, to line wells and to catch houses, and are plaited into baskets and mats for boats. The young shoots form a nutritious food for goats and cattle.

Dromedaries and asses constitute the principal means of conveyance by land. The dromedaries are reared in great numbers, but they are not equal in strength and size to those of the neighbouring countries. The horses of Sind are small and inconstant, but harsh and spirited. There are not very many and horses and asses are imported from Afghanistan and Persia. Mules are only kept at a few places. Immense herds of buffaloes graze on the banks of the Indus and its arms, and at other places they are penned. There are five very important articles of export. Sheep and goats are met with almost everywhere in Upper Sind, and wool is exported from that tract which lies west of the Indus and north of Shikarpore.

Fowls are plentiful in some places; and tigers, wolves, jackals, wild hogs, porcupines, deer, and hares live in the woods. The tiger is only seen north of Bokhur. Hogs are very numerous, and very destructive to the fields. Among the amphibious animals are the alligator, otter, and badger. Badger and otter skins form an article of export to Afghanistan. Snakes, scorpions, and centipede abound in rocky situations. Among the birds are a peculiar kind of myraptor, or bee-eater, the black partridge, the grey plover, the quail, two kinds of woodpecker, the razor-beak, several kinds of gulls, the pelican, and a species of plover. Geese, ducks, divers, and the black water-fowl are plentiful at the banks of the Indus and those of Lake Munchar, as also on the swampy grounds; they form part of the food of the lower classes.

Fish abound in the sea, the Indus, the lakes, and the fisheries in the river and at its mouths are extensive, especially on the Gora Bank. The fins of small sharks, which abound near the Indus, form an article of export to China. As the three-fifths of the fish of the delta have been killed, the most important is called *polua*, and is a kind of carp, which is of delicious flavour, and caught in great quantities, but only in the four months that precede the swell of the river.

In the Murree and Boogtee hills, a spur of the Sulimian range, sulphur and alum are found, and form articles of trade. In the delta and other places the soil is impregnated with salt, and some is collected for home consumption. Not a portion of any kind besides waterstone, procurable in the Indus and Burce is found in the level parts of the country.

**Population and Inhabitants.**—Sind is a thinly peopled country; the whole population is stated not to exceed one million, but it appears to be underestamped. The greatest part is a desert, on which only some nomadic tribes wander about with their herds, and the bulk of the population is settled on the banks of the Indus and on the canals which are fed by its waters. The best populated districts extend from Shehwun on the south to Bokhur and Shikarpore on the north.

The population is divided into three distinct classes, the Sind ee, the Bheeleh, and the Hindu. The Bheeleh form the bulk of the population, and are divided into the lower and upper classes, and the former, who are generally termed Bheels, or Boolehooos, form the bulk of the people. The Hindu amount to about 200,000, and are divided into two classes, one of which consists of the Hindus proper, and is occupied chiefly in trade; the other is formed by the large number of traders and adventurers who have abandoned their occupation. In this last, however, have managed to make their way into the midst of the Bheels by degrees, and have formed a sort of a middle class, from which they gradually descend to the common herd of the people. The Bheels are divided into four distinct tribes, the individual members of which are connected by relationship, but the whole body is composed of a Hindostan and others which are termed Bheels, from the being the sole property of that nation. The Sind ee are the less fixed part of the population, being scattered over the whole country, whilst many thousands lead nomadic lives, moving their villages with the rise and fall of the river Indus; they are also boatmen and fishermen. The Bheels settled in Sind preserved their language, but the Sind ee, who have been鞑靼ized and who belong to a degree of wealth and considerations, the Indus was taken possession of by the British, but they are now entirely entitled to the greatest part of these classes and tribes are dispersed over the plain which lies between the Indus at Bokhur and the Beeman Pass, where till of late years they much impeded the passage of the caravans by their depredations. Some of these clans however have abandoned their wandering life, and become cultivators of the ground. The Bheels have adopted the language of the Hindustan, which however is considerably mixed up with Pushtoo and Peshawar. The language of the Bheels is quite different, and almost written in another alphabet. The Sind ees are a mixture of Guzeratees, Tamul, and Munsali and a corrupted Marwari. There are no colleges, libraries, or public schools in Sind, but the higher classes are well versed in Persian literature, and read and write that language.
Divisions and Towns.—Sinde is divided by the natives into two parts: Lar, which comprehends the southern portion as far north as Sehwan; and Sirra, which extends over the northern districts. Lar contains the three seaports of the country—Shah-Bunder, built on the Mull mouth of the Indus, is a small place, accessible for sea boats of 25 tons burden; it exports rice. Vikur, situated on the Hojammoo mouth, 55 miles from the sea, is a fine river being navigable to the place for more than 35 miles for sea boats of 40 tons burden; it exports the produce of the delta. Kurachee, on the west, and about 30 miles from the mouth, is the metropolis of the Indus, the Pittar. Built on the bank of a creek distant from the sea; a little market. A harbour, at its entrance protected by a high headland, affords safe anchorage at all seasons to vessels of 2000 tons, from its fine, large coasting barks. The town, which is built on a slightly rising ground and surrounded by a mud wall. The bazaars are extensive, but the streets are narrow and filthy. The inhabitants amount to 14,000, and carry on an extensive trade by sea with India, Arabia, and Persia, and by land with Shikarpore.

Hyderabad or Bunder, the present capital and seat of the government, is built not far from the east bank of the Indus, between the Chiver and the Feroom, on a rockyeminence. It has no remarkable buildings, and the population, amounting to nearly 30,000 individuals, live in mud huts. Nearly half-way between Hyderabad and the Hojjamoo mouth of the Indus, is the town of Euphrates. town of Shikarpore, is washed by the river, but is now five or six miles distant from it. It presents only a heap of mud ruins, and at present contains scarcely 8000 inhabitants. Some good cotton fabrics are still made here. An ancient hotel, or house of boats, is the town of Furrat, and Sirra, on the western banks of the Indus, is the town of Jurruck, which is built on a hill 150 feet high, has a good bazaar, and 4000 inhabitants. Moepore is built on a canal which runs eastward from the Indus, forming a branch into the interior and fertilizes a very large tract of country. This town has mud walls enclosing a circuit of three miles, and contains 10,000 inhabitants. There are more than 300 shops in the bazaar. It was founded by the last Ameer of Sirra, and is built near the edge of the Thurt. It exports the produce of the desert, and contains 2000 inhabitants, chiefly Rajpoots.

Sirra, or Upper Sinde, contains several large places, especially the west of the Indus. Sehwan, a large and formerly an important commercial place, is built on a rocky eminence not far from the place where the Arrul, or Western Nara, river joins the Indus. It contains between 10,000 and 12,000 inhabitants, and carries on an active trade with the fertile country to the north. The road between Kurachee and Shikarpore passes through this town. On the banks of a canal, 3 miles from the town, is the town of Kyrhojan, which has seven mosques, and between 2000 and 3000 inhabitants, and is a thriving place. Further north, on another canal of the Western Nara, is Larkhana, situated in a fertile plain, is an important place, and contains about 2000 inhabitants, and is exporting in large quantities; it has 12,000 inhabitants. Shikarpore is the principal emporium of Sinde. [SHIKARPORE, P. C. S.]

On the eastern banks of the Indus stands the town of Roeo, which is built on a rocky eminence, and contains about 8000 inhabitants. The streets are narrow and the houses built of sun-burnt bricks; many of them have three or four stories. Opposite this place, on an island of the river, is the fortress of Bukkur, and on the other side the small town of Sukkur. Kyrhojan, built on the canal of Meerwah, is a miserable-looking place, but it has for some time been the residence of one of the princes of the Talpore family; it has 18,000 inhabitants; the bazaar is spacious, and in the centre of it was the chief's residence. Subulcote lies on the road leading from Roeo to Bawulpore; it has some trade in the produce of the country, especially grain, hides, and opium.

Manufactures.—The manufactures of Sinde are not numerous; but they may be considered extensive, when the scarcity of the population is considered. Cotton-cloth of a coarse description is manufactured in the principal towns and villages, chiefly for home consumption, and a little is exported to Afghanistan and Persia. Among the silk manufactures there are several different kinds; the best are those called the laris, a rich fabric of silk, cotton, and gold, variegated in pattern and of close texture. Common laris are fabricated in the villages of Raneepore, Gumbat, Khooor, and Duroo, situated near to one another, south of the town of Kyrhojan.

They are chiefly of cotton with silk borders, or a few of silk and cotton mixed, and inferior to those of Tatta and Bawulpore. Some silk cloths for the lower classes are woven at Roeo, Kyrhojan, Shikarpore, and Sehwan. A peculiar kind of caps called Shoojahs, are used by all people, and are chiefly made at Shikarpore, Roeo, and Sehwan. In Lower Sinde are numerous tanneries, in which good shoe-leather is made. Shoes are exported to the neighbouring countries, but they are inferior to those worn by the British. There are manufactories of paper and gunpowder in all large towns. The best paper-manufactories are at Shikarpore and Larkhana, but their produce is inferior to that of Cashmere and Jaffn," said the British commander.

Commerce.—When the British occupied the main part of Sinde, it was concentrated in that of Sinakooran, under which an account is given of it. Roeo parts of the commerce carried on between Shikarpore and Bawulpore. Kurachee has some commerce with Arabia and Persia, and we have no account of its extent and the articles of export. A commercial relation between this place and Bombay has lately sprung up, which probably will become of importance.

History.—Sinde became known to Europeans by the expedition of Alexander the Great, who followed the course of the Indus to its mouth, and constructed a fleet, which sailed along the coast and up the Persian Gulf to the mouth of the Indus. Shikarpore was the place where the city of Sambus mentioned by Arrian. [ALEXANDER, P. C., p. 201.] It appears that at this time the country was divided among a number of independent sovereigns. Nothing is known of the political changes that have taken place since the middle of the world before Mahommed of Ghizni conquered a part of Hindostan and subjected Sinde to his rule. Since that time up to the last century, Sinde appears always to have been an independent country, which comprehended all the northern parts of Hindostan. But by the peace, which Shah Nadir concluded in 1739 with the Mogul emperor, Sinde was dismembered from it and became a part of the Persian monarchy. After the death of Shah Nadir (1747), Ahmed Khan founded the kingdom of Afghanistan, and Sinde was annexed to it, but the government of the country remained in the hands of a Belooch family, the Kalhoras, who before that period had settled there and acquired great authority. Among the other Belooch tribes settled in the country was that of the Talporees. Their chief, Byram Khan, was minister of Mirjan Surluxan Khan, the Khalora ruler, and was with one of his sons cruelly put to death by him in 1774. His death produced violent disturbances in Sinde, owing to the extensive influence which he had with his tribe and the country. In 1781 Beur, another son of Byram Khan, shared the fate of his father and the same fate; and also Byram Khan; this exasperated the Talporees, who rose in a body, and having dethroned the tyrant, raised Futtih Ulee, the grandson of Byram and chief of their tribe, to the government. Times were more peaceful during the reign of Shah Nadir, and Sinde was tributary, endeavoured in the commencement of the struggle to restore the Kalhoras, but he had too much to do in the Punjab to assist them effectually, and he thought it prudent to invest the Talporees formally with the government. The Talporees divided the country into three unequal parts, and each of the three families of which it consisted received a portion of the country. These sovereigns were called Ameers.

When Shah Shojoah had lost the throne of Cabool, these sovereigns considered themselves as quite independent, and in 1834, when he made an attempt to recover the throne of Cabool, they refused assistance, and opposed the march of his army through their territories. But he beat them in a battle fought seven coins from Roeo, and obliged them to pay seven lakhs of rupees, and to form him the distinction of Shikarpore. Meanwhile Sir Ahmad Shah-Durrani visited Sinde (1831) and a treaty of commerce had been concluded between the Ameers and the British government, by which the Indians were to open Cabool to the British. No advantage to British commerce had resulted from this treaty, when the British resolved to replace the dethroned Shah Shojoah on the throne of Cabool. The Ameers, who were still to be considered independent, opposed the march of the British army through their countries to the Bolan Pass, and surrendered by treaty the fortress of Bukkur and Kurachee to the British commander. When however the British armies in Afghanistan were nearly destroyed...
(in 1841), a spirit of insurrection manifested itself in Sind among the Beloochee tribes, which however subsided when the British army had again advanced into Afghanistan. As the navigability of the Indus for flat-bottomed steam-boats was now ascertained, the British wished to retain the places in Sind which were still in their possession, and they attempted to establish a free navigation by a new treaty. The Afghan Government had not the strength to resist the British willing to go back to the proposed conditions, except one, that is, to permit a track-road to be made along the banks of the Indus, because such a road would partly destroy their shikargars along the river. But the British were quite prepared for the change of the arrangements, to their large extent of the shikargars. It was however soon evident that this was only a pretext for breaking the treaty; the narrow track-road along the banks of the river, required for a track-path, would not only diminished the immense extent of their shikargars. The negotiations were speedily broken off, when an army of 22,000 Beloochees was ready to attack the British, and to expel them from Sind. Sir Charles Napier, who commanded 3000 men, British and native troops, stationed at Bukkur and its vicinity, immediately put them in motion. He found the army of the Ameers near Meaneer, a place near the spot where the Fulahlee branch leaves the Indus. On the 17th of February, 1843, an obstinate battle was fought at Meaneer, between the British troops and the Beloochees. It was fought with the same spirited resolution with which the Beloochees were completely defeated. They lost 6000 men, with all their artillery and military stores. The Ameers, six in number, came to the British camp and surrendered unconditionally. On the 24th of February, the capital of Gujerat was taken, and the entire possession of the British. The Ameers were removed to Bombay and received liberal allowances. Thus Sind became a portion of the British empire in India. Partial insurrections followed, especially among some of the most powerful Beloochee tribes, but the activity of the governor of Sind, Sir Charles Napier, has put them down, and Sind begins to enjoy that peace and prosperity which the British army have so often conferred on or secured to other parts of Hindustan.

SINGLETON, HENRY, was born in London, 1796. His father died while he was an infant, and he was brought up by an uncle, William Singleton, a miniature-painter, who gave him instruction in the practice of Miniature-painting, and also was his intimate studies with him. At the age of eighteen he obtained the first silver medal for drawing in the Royal Academy; and in 1788 he obtained the gold medal for the best drawing of monument in the Academy. He was next in the competition of Mortier's "Odyssey Alexander's Feast." The medal was presented by Sir Joshua Reynolds, the last time but one that he presided at the distribution of the Academy prizes, and he is said on the occasion to have exclaimed, "How much are the prices of Microscopists?" He also was a frequent exhibitor with him. At the age of eighteen he obtained the first silver medal for drawing in the Royal Academy; and in 1788 he obtained the gold medal for the best drawing of monument in the Academy. closed at the lower and open at the upper extremity; and the open end of the cylinder is screwed to the table of the air-pump immediately about the orifice of a brass tube which passes directly under the orifice of the receiver, and which, passing through the pump-plate, opens into the receiver, and the lower end being immersed in a small cistern of mercury; for the air in the receiver and that in the barometer tube having the same density, the quantity of rarefaction is directly proportional to the pressure of the external atmosphere on the surface of the mercury in the cistern forces mercury into the tube, so that, if the exhaustion within the receiver could be carried far enough, the column of mercury would stand at the same height in the tube as it stands in the tube of an accurate barometer, and would indicate a perfect vacuum in the receiver. The degree of rarefaction in the receiver is consequently indicated by the number of inches expressing the height of the column of mercury in the tube. The siphon-gauge is also provided with a scale of inches which are decimally subdivided; but, while the pressure of the air in the receiver and in the barometer-tube is the same, the indication of the siphon-gauge in relation to the weight of the column of mercury in the closed branch, the gauge presents no indications: from the time however that, by continuing the process of exhausting the receiver, the pressure of the air in the barometer-tube was taken off, the column of water in the siphon-gauge indicates the height to which the column of mercury in the other, that column descends in the latter branch and rises in the former; and then the degree of rarefaction in the receiver is indicated by the difference between the two; the height of the column of mercury in the two branches of the siphon.

The Pear-Gauge alluded to in the article Air-Pump, P. C., and a description of which has been inadvertently omitted, was also invented by Smeaton for the purpose of determining the degree of rarefaction attained in the receiver of an air-pump. It consists of a small glass vessel nearly similar in form to a pear, or rather to a Florence flask, terminating in a cylindrical stem; the upper or smaller extremity is hermetically sealed, and the lower extremity is open. To the upper extremity of the gauge is affixed a wire which passes through an air-light orifice at the top of the receiver on the air-pump so as to be capable of sliding up and down, carrying with it the gauge in the interior of the receiver; and under the lower extremity of the gauge is a vessel of mercury. When the receiver has been exhausted as much as may be thought proper, the gauge is pressed down till its lower or open extremity enters into the mercury in the vessel below it; at which time, evidently, the air in the gauge will have the same density as the air in the barometer-tube. Then, on admitting the air into the receiver, its pressure on the surface of the mercury in the vessel about the bottom of the gauge will force mercury into the latter, when the air which, in its rarefied state, occupied the whole interior of the gauge, will be brought to the same density as that in the receiver, and consequently as that of the atmosphere, and will occupy only a small space at the upper extremity of the gauge. A graduated scale serves to show the volume of the air in its compressed state; and this, being compared with the known volume of the whole gauge, serves to determine the degree of rarefaction which had been produced by the partial exhaustion of the air. At the time when the siphon-gauge and pear-gauge were invented, it was the custom to place the receiver of the air-pump on a ring of leather soaked in oil and laid on the pump-plate, in order to prevent the atmosphere from entering the receiver during the process of exhaustion; when, on the air within being rarefied, a quantity of elastic vapour extracted from the moisture occupied the receiver; now the barometer and siphon gauge, as well as the pear-gauge, having been converted into a siphon-gauge, and the air-vapour, is diminished by the partial exhaustion; but, in employing the pear-gauge, which, during the process of exhaustion, contains a portion of the elastic vapour, on re-admitting the air which had been extracted from the body of water, and the gauge shows only the quantity of pure air which is left in the receiver after the exhaustion. This discovery was made by the Honourable Mr. Cavendish on wit-
there, they determined upon emigrating to the country of their ancestors, and arrived at Florence in October, 1798. They invested the produce of the estate which they had sold in purchasing a small farm in Valsugna near Pavia, a spot selected by the young Simondi. Here he divided his time between the active superintendence of his farm and the preparation of a work which he had projected during his travels, entitled "De la Richesse Commerciale, ou Principes d'Economie Politique appliquées à la Législation du Commerce." This work he began to write immediately on his return, and in 1819, published at Paris under the title "Nouveaux Principes d'Economie Politique." The views of Adam Smith (Smith, Adam, P. C.) are almost implicitly followed in this treatise, and, as they happened to coincide with the popular notions on the subject, they brought the writer into repute. The vacant chair of political economy in the university of Wilna was soon after offered to him by Count Plettenier, who came purposely to Geneva to urge in person his proposal. Though the offer was made, as the account which the writer received of it, the acceptance of it on that account urged upon him by his parents, it was declined by him from his dislike to teaching. He was at this period that Simondi began to apply himself earnestly to historical investigations, and, by the advice of his mother, a woman of cultivated mind and sound understanding, to devote himself chiefly to the study of history.

His residence at Geneva, though it was enlivened by his enjoying the intimacy of several literary persons, such as Benjamin Constant and Madame De Suel, could not deliver him from the desponding feelings which are so common to the young author, and, to the suggestion of his earnest mother, he was induced, in 1806, to accompany Madame De Stael on a tour through Italy. Sympathy of literary tastes had produced the sincerest friendship between these two distinguished literary persons. The interest of their life was shadowed together in that classical country, and the poetic charm cast upon them by the conversation of the authoress of "Corinne," (Stael, Anne Germaine de, P. C.) fixed the determination of Simondi to induce it in the path of learning and his ancestors in the page of history. The first-fruits of his historical studies appeared in the first two volumes of his "Républiques Italiennes," which were published at Zürich, in 1807. His publisher, G enerst, is stated to have dealt hardly with him, and the publication of the subsequent volumes, the last of which appeared in 1818, was transferred to Treuttel and Wurtz. A new and more complete edition, in sixteen volumes, appeared during the years 1826 and 1827, both at Paris and Brussels. In the composition of this his first and most important historical work, Simondi has been blamed for his insufficient use of public archives and private collections; he is, however, acknowledged to have carefully consulted every printed book from which he could derive information. It is to this conscientious examination of authorities, the result of personal research, that the value of this work, the "Républiques Italiennes," as a historical truthful record, is chiefly due. The style is pleasing and attractive, but, though a good French scholar, he never hesitates to use an authoritative authority when it is necessary to convey meaning with greater precision. The part of the work, which is generally considered to be most defective, is that which treats of the development of the republican constitutions and institutions in Italy, as both in Italy and France the biographer is not an eyewitness of the events he narrates. The manuscript pages of his history to his mother, and, with the humility of filial obedience, to lend an attentive ear to the corrections she suggested. To her pious care he has gratefully acknowledged the benefit, and not a little of the success he has attained as an author; in his desponding moments she was ever a present comforter, and the rough path to literary fame was softened by her counsels and cheered by her example.

In 1811 he delivered at Geneva a course of lectures upon the Literature of the South of Europe, which were printed at Paris in 1813, and a third edition, in four volumes, was published in 1829. It comprises an introductory history of the decline of the Latin language and the formation of the languages of Southern Europe, and presents us with a history of Italian, Spanish, and Portuguese literature to the end of the eighteenth century. The portion of this work which treats of the literature of Spain and Portugal is the most imperfect, as the information which it contains is derived from secondary sources.

In 1822 he visited Paris, which at that time presented an interesting study for a political observer; he formed an acquaintance with an illustrious brother historian, M. Guizot, who, when, in 1819, he became Minister of Public Instruction, invited him to Paris, where he resided at the Hotel de France, at Paris, which, however, he declined. During the Hundred Days a series of lectures, which he published in the Moniteur, on the French Constitution, attracted the attention of Napoleon, who requested an interview with the author. The interesting details of this interview were immediately after reported by Simondi to his mother, and an abridgment of them may be seen in the article of the "Quarterly Review" referred to at the end of this year.

In the year 1819 Simondi began his longest, and, as it is by some considered, his best work, "L'Histoire des Français," which occupied him till the close of his life. It was not at first the intention of the author to bring down this history to a later period than the Edict of Nantes, which terminates the twenty-first volume; he was induced to continue it, on a more abridged scale, to the period of the Revolution, but he carried it no further than the year 1790. His principal motives for undertaking this important work were, the connection of French history with Italian, and the fact that French literature possesses no history of the kind which can be looked upon as a work of authority. To those motives he added the great interest which Simondi evinced in the affairs of a country which he had adopted as his own. He has not, however, allowed his bias in favour of France and the French to interfere with his judgment; he has been in all respects impartial in the presentation of it. So little indeed did he seek to gratify in it the national vanity, that he has not hesitated to expose the weak foundation on which had rested undisturbed for centuries many traditions and even the authority of a name, and, as far as his account responded to the popular feeling, had been fondly cherished in the memory of the people.

The history is divided into eleven periods: the first the history of the early races of French kings, the Merovingian, Carolingian, and early Capetian races, to the accession of Louis X.; the fourth brings it down to the death of Charles IV., 1328; the fifth, from the death of Philip in Valois to Charles V., 1429; the sixth, from 1429 to 1515; the seventh, and most interesting, presents us with the reign of Francis I., and is a beautiful specimen of historical portraiture, in which the colouring is so perfectly blended with the ideas that the reader is no more exaggerated than the eighth embraces the period of the religious wars of Francis I., which are treated of with an impartiality scarcely to be looked for in a Genevan Protestant; the ninth is the reign of Francis II., and of the death of the young Prince, and the Bourbon, and here, more perhaps than in any other part of his writings, may be seen the honest spirit by which he was actuated; indeed in his endeavour to be impartial, he has perhaps sometimes indulged in an unseemliness, as a consequence of his reverence for the name of Henry IV. The last three periods embrace the history of France under the Bourbons to the latter period of the reign of Louis XV. (Francé, P. C.)

In the year 1830, after finishing, in "Lambert's Cabinet Cyclopaedia," an abridgment, in English, of his "Républiques
Italianians; a French edition of this work appeared in Paris in 1832, under the title ‘Histoire de la Renaissance de la Fabrique d’Italie.’

The last and least known of his historical works is entitled ‘Histoire de la Chute de l’Empire Romain et du Déclin de la Civilisation.’ This work, which was published at Paris in 1833, describes the history of 750 years, from A.D. 250 to 1000; the other writings of Sismondi are of the same general nature as described above—albeit an historical novel in imitation of Sir Walter Scott, in which he describes the condition of Gaul at the time that Rome was a great and prosperous city; it was published at Paris in 1822: 2. ‘Etudes sur les Sauvages.’ Published at Paris in 1816, this work contains a collection of articles which he had previously contributed to various periodicals: 3. ‘De la Vie des Peuples de l’Asie.’ Published at Paris in 1807, in 8to.

The above is a brief account of the life of Sismondi; but it would be doing injustice to his memory to omit some of the details of his private life and character which have been recorded by his biographers. Surrounded by a circle of all that was most distinguished in literature, he was conscious among them for the amiability of his disposition and the devotedness of his friendship. Though he never reached a state of affluence, he was liberal in contributing to the necessities of the poor, and he is said to have spent considerable sums in the furtherance of causes which had political freedom for their object. Fond of society, he never allowed his inclination for the trimming of the garb to which he had marked out for study, usually nine or ten hours a day. The time be allotted to this object was never broken in upon, except to assist a friend or to alleviate misfortune. As a public character he displayed no indifference to the matters of his national politics, and he was careless of the unpopularity which this conduct often entailed upon him. About the year 1840 he felt the first symptoms of the cruel malady to which he fell a victim, which was a cancer in the stomach. A short journey which he made to England appears to have aggravated his disease; but his sufferings, though intense, scarcely interrupted his application to study, and he never spared himself to the point of death. Indeed three days before his death, which occurred on the 25th of June, 1842, he was occupied in correcting the last proof sheets of his ‘Histoire des Francs.’

Sismondi married, in 1819, Miss Allen, sister to the late Mr. Allen of Crastilly, member of parliament for Pembroke, and to the second wife of Sir James Mackintosh. [Mackintosh, Sir James, P. C.]

The following extract, which we translate from the conclusion of ‘l’Histoire des Francs,’ will be found an interesting supplement to this biographical sketch of Sismondi:—‘My life has been divided between the study of political economy and history; in this last, the current of events is not political economist will ever be discovered conjointly with the historian. I have endeavoured to prevent those lessons being lost which experience has given us on the causes which contribute to the formation and renewal of the human and political societies; Subcutaneous Ichthyosis, Argenteum. above all, I have always looked upon wealth as a means, not as an end; I have always inquired respecting it, whether it really advanced the well-being of all classes, and I trust my readers will discover that I have taken in the welfare of the cultivator of the land, the artisan, and in the poor, who has to earn his bread by the sweat of his brow, that all my sympathies belong to the needy and suffering classes of the community.

SKIN DISEASES OF. The healthy functions of the skin and its structure have been described under Skin, P. C. Most of the diseases of the skin have been described in this work under the head of their particular names. In this article we shall only arrange them in the alphabetical order, and a description of those which have been omitted. The following arrangement is that adopted by Bayer in his work on diseases of the skin.

Class I. Inflammation of the Skin.

Order 4. Pustulosis. Verruca, Varicela, Varicium, Vacci-...
extensive, and the tendency to inflammatory action in the skin so strong as to produce pustules instead of vesicles. Such are the three forms of Eczema, usually described by writers on diseases of the skin—E. solaris, E. rubrum, E. impetiginosus. Eczema is more likely to be confounded with itch than any other disease, from which it may be distinguished, among other causes, by the catabrosis of the person attacked, which is called E. mercuriure.

The treatment of Eczema must be adapted to the causes which have produced it. According to the general state of health, and the duration of the affection, the treatment may be either acute or chronic. In slight cases of acute eczema require only a simple treatment, a light diet, saline purgatives, and cooling or emollient applications to the part being all that is required. In some cases the inflammation is great and the pain intense, and where this occurs bleeding and a more active general treatment should be had recourse to. Chronic eczema is much more difficult to treat. The general health demands attention, and alternates and tonics, according to circumstances, are demanded. Astringent lotions and ointments, such as the preparations of silver, zinc, alum, &c., may be used; sulphurous baths, and various mineral waters have also been recommended in chronic cases of this disease. The tincture of cantharides and the preparations of arsenic have also been employed in the chronic forms of eczema.

Millaria (Fibris milliari, Millary Eruption) is also a vesicular affection, and is characterized by multiple small pustules. It is accompanied with inflammation of the gastro-intestinal mucous membrane, and is accompanied by profuse sweating. Millaria as an epidemic and independent disease is only seen between the 45th and 48th degrees of latitude, and its existence has been doubted by some nosologists. It frequently accompanies other diseases, and retires with the cessation of the disease which it attends. When the fever accompanying it is slight, the treatment is a gentle and purgative diet. As demilements will be found sufficient. In the epidemic form however it is often a formidable disease, and requires the same treatment as other epidemic contagious fevers.
